A New and Complete DICTIONARY OF Arts and Sciences.

Including the latest Improvement and Discovery

And the Present State of every branch of Human Knowledge.

BY G. GREGORY. D.D.

Domestic Chaplain to the Bishop of Landaff. Author of the Economy of Nature &c. &c.

IN THREE VOLUMES.

Vol. I.

first American edition considerably improv'd & augmented.

SURGEON GEN'L'S LIBRARY 112168.

PHILADELPHIA.

PUBLISHED BY ISAIC PEIRCE,

No. 316 Market Street.

1816.

A

DICTIONARY

OF

ARTS AND SCIENCES.

BY G. GREGORY, D. D.

DOCTOR IN PHILOSOPHY AND THE ARTS, AND HONORARY MEMBER OF THE IMPERIAL UNIVERSITY OF WILNA; MEMBER OF THE MANCHESTER AND NEWCASTLE LITERARY AND PHILOSOPHICAL SOCIETIES; HONORARY MEMBER OF THE BOAD OF AGRICULTURE; DOMESTIC CHAPLAIN TO THE LORD BISHOP OF LANDAFF; AUTHOR OF ESSAYS HISTORICAL AND MORAL, THE ECONOMY OF NATURE, &c. &c.

IN THREE VOLUMES.

VOL. I.

FIRST AMERICAN, FROM THE SECOND LONDON EDITION,

CONSIDERABLY IMPROVED AND AUGMENTED.

PHILADELPHIA:

PUBLISHED BY ISAAC PEIRCE, No. 12 SOUTH FOURTH STREET.

1815.

TO THE RIGHT HONOURABLE

THOMAS, LORD ERSKINE,

BARON ERSKINE OF RESTORMEL CASTLE, IN THE COUNTY OF CORNWALL,

LORD HIGH CHANCELLOR OF GREAT BRITAIN, &c.

MY LORD,

THOUGH a Dedication is in general an expression of gratitude from an Author to his Patron, or of friendship from one literary character to another, yet I cannot but be of opinion, that there should be some accord between the character of the Work and that of the Patron to whom it is presented.

In this point of view the world will see the propriety of a Work which professes to treat of the Sciences and the Arts in general, being inscribed to a nobleman who unites in himself more various, as well as more splendid talents, more general knowledge, and more diversified taste, than any other public character of the present age; who, deservedly filling the chair of Bacon, possesses the same excursive and expanded genius; but whose public duties, being more onerous than they were in the time of that great man, alone preclude him from gratifying and enlightening the Public by researches out of the line of his profession.

If a private sentiment might be indulged on such an occasion, the Editor would add, that your Lordship's unremitted zeal for true Religion, and your tried and disinterested Patriotism, must for ever endear the name of ERSKINE to every friend of liberty, piety, and active virtue.

That your Lordship may long continue to serve your country, and promote the best interests of humanity, in the arduous situation to which the Divine Providence has been pleased to call you, is the fervent prayer of,

My Lord,

Your Lordship's

Ever faithful humble servant,

G. GREGORY.

West Ham, Jan. 20, 1807.

PREFACE.

FROM the time of Chambers, Dictionaries of Arts and Sciences have been increasing in magnitude, without, it is to be feared, a proportionable increase of utility. The authors appear to have regarded it as a kind of sacrilege to retrench, while they have equally thought it their duty to add every thing that came within their reach. Hence not only obsolete terms, but obsolete sciences, as magic, alchymy, and astrology, have been retained even in works of high character, and otherwise of distinguished merit. Hence, that which was new even in the living sciences, has been combined with what had been long since exploded: a practice calculated not only to confuse but to mislead.

It was upon this view of the subject it occurred to the editor of this work, that in framing a new Dictionary, selection was a more urgent duty than accumulation; that perspicuity, not less than convenience, would be consulted by reducing the size; and that whatever is practically useful in science and in art might be compressed within a smaller compass than had been commonly imagined. However deficient he may have been in the execution of his plan, he has the satisfaction to say, that in this idea he was not deceived or disappointed.

A dictionary of this kind is intended for two purposes: first, as a book of reference, to lie on the table of a man of letters, for occasional consultation where recollection has failed, or where a subject occurs in reading or conversation which had not previously come within the course of his studies. The second is, to serve as an introductory or elementary work for students, or for those who may not have leisure to bestow on the great works of science, or to travel through the many volumes which at this time almost every branch of knowledge includes.

The first of these ends, it is humbly presumed, will be sufficiently answered by the present publication. Most of the technical terms in science and the arts, are inserted with a proper definition or explanation, in the alphabetical order; or should there be a casual omission, the word will still be found under the head of the science to which it belongs, and probably in the index to the treatises at the end of each volume. To some sciences it was found necessary to attach a glossary. The technical phrases, however, in anatomy, surgery, &c. are generally referred to those branches of science expressly treating of them, that nothing may appear, on casually opening the book, to offend the most modest or delicate reader. Terms also which now constitute a part of common colloquial language, and which, therefore, every person must understand, have been omitted.

With respect to the second object, no pains have been spared in preparing those articles which treat of the respective sciences. In a work of this nature it cannot be expected that the whole should be original, nor could it in that case answer so well the ends for which it is designed. An Encyclopedia is in its nature a compilation; and its best commendation is, that it amasses together the best information from the best sources. Yet in this work there is much original composition; and such is the progress of science, that it contains scarcely any articles of importance which are to be found in any similar publication.

In order also to facilitate as much as possible the study of the sciences, every attention, consistent with the nature of the work, has been paid to method; and the student will not be much at a loss to distinguish the order in which the several parts of each science are to be read. Thus, under Natural History, he will find a synopsis

of the several branches, the classes and orders, and under these the names of the genera; under Zoology, again, he will not only meet the classes and orders, but also an immediate reference to the genera. Under Chymistry, he will find the outlines of the science, and references to the different branches, which are treated more at large in other parts of the work. Thus under Furnace and Laboratory, is included the whole of the apparatus; and he will then turn to Air, and the simple substances as they stand enumerated there, or under the word Elements. Astronomy and Mineralogy, he will see, have similar references. Electricity, Hydrostatics, Hydraulics, Magnetism, Mechanics, Meteorology, Optics, Pneumatics, and the Medical Branches, are complete in themselves. Those articles which relate to the Arts are also complete. Those which treat of the different subjects of Trade and Commerce are also complete, and contain all the new information which could be obtained on those important topics.

The Editor cannot conclude this address without frankly stating, that whatever may be thought of the merits of the new Dictionary of Arts and Sciences, they are more to be attributed to the very able assistance with which he has been favoured from different quarters, than to his own exertions. He wishes he could make his acknowledgments in terms equal to his sense of the obligation. To his industrious and truly able coadjutor, the Rev. Mr. Joyce, he is indebted for much general assistance, and for the exclusive superintendence of all the mathematical and astronomical articles. A similar acknowledgment is due to his friend and neighbour, Luke Howard, Esq. particularly for his attention to all those articles connected with the almost new, and important science, Meteorology.

The public will estimate better than he can point out the extent of his and their obligations to Mr. Grellier, of the Royal Exchange Assurance Office, when he mentions, that all the articles relative to Trade, Commerce, Political Economy, Finance, and Revenue, were drawn up by that gentleman.

The Medical and Physiological articles were written by Dr. Uwins, of Somers Town; Husbandry and Surveying by Mr. Crocker, of Froome; Rhetoric by Dr. Thomson, well known as the Continuator of Watson's History; Architecture by Mr. Henderson, the plates by Mr. Moore; Exchanges by Mr. P. Hamsbrow; Farriery by Mr. Lawrence; and Anatomy by Mr. A. Walker.

Those articles which are connected with History and Antiquities, have been furnished by a distinguished scholar, as will be easily perceived; those relative to the Fine Arts, by a gentleman well known in the literary world; Poetry by a lady, who, like Vida, has asserted her title to the character of a critic, by having excelled in the art itself; the Military articles are the production of a literary gentleman who was educated in that profession; and some of the principal Law articles are by a member of one of the inns of court. Besides these, the editor has been favoured with single communications from Dr. Mavor, Mr. M. Smart, and several correspondents who desire their names to be concealed.

A

DICTIONARY

OF

ARTS AND SCIENCES.

A, the first letter of the alphabet, is used, on many occasions, as a mark, or abbreviation. Thus, in the calendar, it is the first of the dominical letters: among logicians, it denotes an universal affirmative proposition; as a numeral, A signified one among the Greeks; but among the Romans it denoted 500, and with a dash over it, thus, $\overline{A}$, 5000. The Romans also used it on public occasions for *antiquare*, to antiquate or reject a proposed law; as did the judges of the same people for *absolvo*, I absolve or acquit; whence it had the name of *litera salutaris*. A is frequently also met with, denoting *Aulus*, *Augustus*, *Ager*, *Aiunt*, &c. A.A. stands for *Augusti;* A.A.A. for *aurum*, *argentum æes;* and, among chymists, for *amalgama*. A.M. is used for *anno mundi*, *artium magister*, or *ante meridiem;* A.A.U.C. for *anno ab urbe condita;* A.B. for *alia bona*, or *artium baccalaureus;* A.C. for *acta causa*, *alius civis*, or *ante Christum;* and A.D. for *anno domini*. On ancient medals, A. stands for *Argus*, and sometimes for *Athens;* but on French coins of modern date, it is the mark of the mint of *Paris*. A, *a*, or $\overline{aa}$, among physicians, denotes *ana*, or an equal weight or quantity of several ingredients. The letter A is also used by merchants, to signify accepted.

AAM, a measure of capacity used by the Dutch, otherwise called haam; it contains 128 mingles, or 288 English pints.

AAVORA, a fruit of a kind of palm tree, found in the West Indies and in Africa. It is of the size of a hen's egg, and is included with others in a large shell. In the middle of the fruit there is a hard nut, which contains a white almond, very astringent, and used in cases of diarrhœa.

AB, in the Hebrew chronology, the eleventh month of the civil, and the fifth of the ecclesiastical year; it comprehended part of July and August, and contained thirty days.

ABACATUAIA. See Zeus.

ABACK, a sea term, which signifies the situation of the sails in a ship, when the surfaces are driven by the wind flat against the mast. They may be brought *aback* by a sudden change of the wind, or an alteration in the ship's course.

ABACOT, the name of the ancient coronet, or cap of state, worn by the English kings, the upper part of which was made up in the form of a double crown.

ABACTORS, drivers away and stealers of cattle in herds, or great numbers. In Spain this crime is very common, and the punishment severe.

ABACUS, in architecture, the uppermost member of the capital of a column. In the Tuscan, Doric, and Ionic orders, the abacus is flat and square; but in the richer orders, its four sides, or faces, are arched inward, with some ornament, as a rose or other flower, in the middle of each arch, and its four corners cut off.

According to Vitruvius, the abacus was originally intended to represent a square flat tile, laid over an urn or a basket. The invention is ascribed to Callimachus; who observed a small basket covered with a tile, over the root of an acanthus plant which grew on the grave of a young lady; the plant shooting up encompassed the basket, till, meeting the tile, it turned back in the form of scrolls. The philosopher took the hint, and executed a capital on this plan, representing the tile by the abacus, the leaves of the acanthus by the volutes, and the basket by the body of the capital. See Architecture.

Scamozzi also uses abacus for a concave moulding in the capital of the Tuscan pedestal.

Abacus, or Abaciscus, in the ancient architecture, likewise denoted certain compartments in mosaic pavements, and the like.

Abacus, among the ancient mathematicians, was a table strewed over with dust, or sand, on which they drew their figures or schemes.

Abacus, an instrument for facilitating the operations of arithmetic, by means of counters. Its form is various; but that chiefly used in Europe, is made by drawing parallel lines, distant from each other at least twice the diameter of a counter; which placed on the lowermost line, signifies 1; on the second, 10; on the third, 100; on the

fourth, 1000; and so on. Again, a counter, placed in the spaces between the lines, signifies only the half of what it would do on the next superior line. According to this notation, the same number, 1806 for example, may be represented by different dispositions of counters. See A and B, in Plate IX. fig. 1.

Abacus *pythagoricus*, a multiplication table, or a table of numbers ready cast up, to facilitate operations in arithmetic.

Abacus *logisticus*, is also a kind of multiplication table, in form of a right angled triangle; each side contains the numbers from 1 to 60, and its area the product of each two opposite numbers.

ABAFT, in sea language, a term applied to any thing situated toward the stern of a vessel: thus, a thing is said to be abaft the foremast, or mainmast, when placed between the foremast, or mainmast, and the stern.

Abaft *the beam*, denotes the relative situation of any object with the ship, when it is placed in that part of the horizon which is contained between a line at right angles with the keel, and that point of the compass which is directly opposite to the ship's course.

ABAGI, a silver coin, current in Georgia, worth about 18 pence.

ABARCA, a kind of shoe, made of raw hides, formerly worn by the peasants of Spain. Some mention another kind of abarca, made of wood, like the French sabots.

ABAS, a Persian weight, used in weighing pearls. It is one eighth less than the European carat.

ABASED, *abaissé*, in heraldry, is said of the wings of eagles, &c. when the tip inclines downward to the point of the shield; or when the wings are shut; the natural way of bearing them being spread. A chevrond, pale, bend, &c. are also said to be abased, when their points terminate in or below the centre of the shield. Lastly, an abased ordinary, is one placed below its due situation.

ABASSI, or Abassis, a silver coin, current in Persia, worth from 16 to 18 pence English. It derives its name from Shah Abbas II. under whom it was first struck.

ABATE, in the manege. A horse is said to abate or take down his curvets, when he puts both his hind legs to the ground at once, and observes the same exactness in all the times.

Abate, in law, signifies to overthrow, demolish, or destroy. It is likewise used to denote the act of him who steps into an estate, void by the death of the last possessor, before the heir can enter, and by this means keeps him out.

ABATELEMENT, is used for a prohibition of trade to all French merchants in the ports of the Levant, who will not stand to their bargains, or refuse to pay their debts. The abatelement is a sentence of the French consul, and must be taken off before they can sue any person for the payment of their debts.

ABATEMENT, in law, signifies the rejecting a suit, on account of some fault either in the matter, or proceeding. Hence, plea in abatement is some exception alleged, and proved, against the plaintiff's writ, declaration, &c. and praying that the plaint may abate or cease; which being granted, all writs in the process must begin *de novo*.

Abatement is also an irregular entry upon houses or lands, and in this sense, is almost synonymous with intrusion.

Abatement, in heraldry, a mark which is attached to a coat of arms, in order to lessen its true dignity, and point out some imperfection or stain in the character of the person who bears it. Abatements are either made by reversion or diminution; the whole escutcheon being turned upside down, or another inverted one added, in the former case; and as to diminutions, they are either a delf, a point, a point dexter, a point champain, a plain point, a goar sinister, or two gussets.

Abatement, in commerce, is a discretionary allowance for damage of goods sold, for a defect of weight or measure, on account of bad markets, &c.

Abatement in the customs, is an allowance made on the duty of damaged goods, upon the judgment of two merchants upon oath, and ascertained by a certificate from the surveyor and landing waiter.

Abatis, in a military sense, is formed by cutting down many entire trees, the branches of which are turned toward the enemy, and designed to guard entrenchments, to cover the passage of a river, to block up roads, &c.

ABATOR, in law, one who enters into a house or lands, void by the death of the last possessor, before the true heir; and thereby keeps him out till he brings the writ *intrusione*.

ABB, in our old writers, is used for the yarn of a weaver's warp; and hence the wool of which it was made, had the name of abb wool.

ABBA, a Syriac term literally signifying father, and used as a title of respect and honour. Slaves were not allowed the use of this term, which explains the meaning of St. Paul, Rom. viii. 15. The Jews assumed the name as a title of dignity; and in many of the eastern churches it is the title which the people give to their bishops. But the bishops themselves bestow it particularly on the patriarch of Alexandria.

ABBE', the denomination of a class of persons in France, who have not obtained any fixed settlement in the churches, but are expectants of one that may happen to become vacant. Their dress is that of an academic, rather than of an ecclesiastic.

ABBESS, the superior of a convent of nuns. The abbess enjoys the same privileges, and has the same authority over her nuns, that the abbots have over their monks; spiritual functions only excepted, of which the sex renders her incapable.

ABBEY, the name of such religious houses as are governed by a superior, under the title of abbot or abbess. Abbeys differ in nothing from priories, except that the latter are governed by priors, instead of abbots.

The abbeys of England, at their dissolution under king Henry VIII. became lay fees: no less than 190 were then dissolved, of between 200*l*. and 35,000*l*. yearly revenue, which at a medium amounted to 2,853,000*l*. *per annum;* an immense sum in those days.

The abbey lands before this dissolution were chiefly tithe free; and these exemptions were continued to the lay possessors by the act 31 Hen. VIII. c. 13.

ABBOT, the superior, or governor of a monastery of monks erected into an abbey or prelacy.

The abbots of the primitive monasteries, from the poverty they professed, and commonly practised, had no other claim to superiority or respect than what arose from the

sanctity of their lives; but afterward, affecting not only pre-eminence over each other, but even to be independent of the bishop, there arose new species and distinctions of abbots into mitred and not mitred, croziered and not croziered, and œcumenical abbots.

Abbots, *Mitred*, were those who were privileged to wear a mitre, and besides enjoyed the full episcopal jurisdiction of their several precincts. Among us, these were called abbots sovereign, or abbots general, and were lords of parliament: they were twenty-seven in number, besides two mitred priors. The unmitred abbots continued subject to their diocesan bishop.

Abbots, *Croziered*, were those entitled to carry a crozier, or pastoral staff.

Abbot, *Oecumenical*, the same with universal, was a title assumed among the Greeks, in imitation of the patriarch of Constantinople: nor have those of the Latin church been backward in this respect; some having called themselves *abbas abbatum*, or the abbot of abbots; and others assumed the title of cardinal abbot.

Abbots, however, are chiefly distinguished, at present, into regular and commendatory; the former being real monks or religious, and the latter only seculars or laymen. These last, notwithstanding that the term *commendam* seems to signify the contrary, have the perpetual enjoyment of the fruits of their abbeys. Anciently the ceremony of creating an abbot consisted in clothing him with the habit called *cuculla*, or cowl; putting the pastoral staff into his hand, and the shoes called *pedales*, on his feet; but at present, it is only a simple benediction, improperly called, by some, consecration.

Abbot is also a title given to others besides the superiors of monasteries: thus bishops, whose sees were formerly abbeys, are called abbots; as are the superiors of some congregations of regular canons, particularly that of St. Genevieve at Paris, and among the Genoese the chief magistrate of their republic formerly bore the title of abbot of the people. It was likewise usual, about the time of Charlemagne, for several lords to assume the title of *count abbots, abba comites;* and that for no other reason, but because the superintendency of certain abbeys was committed to them.

ABBREVIATE of *adjudication*, in Scotch law, is an abstract or abridgment of a decree which is recorded in a register kept for that purpose.

ABBREVIATION, is a contraction of a word or passage, made by dropping some letters, or by substituting marks or characters in their place. Abbreviations are employed in language three ways; in terms, in sorts of words, and in construction. Lawyers, physicians, chymists, &c. use many abbreviations.

Abbreviation of fractions, is the reduction of them to lower terms thus, $\frac{24}{36} = \frac{8}{12} = \frac{2}{3}$, and $\frac{9abx}{3bc} = \frac{3ax}{c}$.

ABBREVIATORS, a college of 72 persons in the chancery of Rome, whose business, according to Champini, is to draw up the pope's briefs, and reduce the petitions granted by him into proper form.

The abbreviators are divided into two parts, or ranks; the one called *abbreviatores de parco majore*, who are twelve in number, and all prelates; the other *abbreviatores de parco minore*, called also *examinatores*, who may be all laymen.

ABBREUVOIR, in masonry, certain indentures made with a hammer, in the joints and beds of stones, in order that the mortar, being received into these, may bind them the more firmly together.

ABCEDARY, Abcedarian, or Abecedarian, an epithet given to compositions, the parts of which are disposed in the order of the letters of the alphabet: thus, we say abcedarian psalms, lamentations, hymns.

These are met with chiefly among Hebrew writers, and as they have but 22 letters in their alphabet, poems of this kind consist of 22 lines, or systems of lines or periods, and every line or period begins with each letter in its order, The cxixth Psalm is a very remarkable instance of this kind. Psalms cxi. cxii. and Lam. iii. are perfectly alphabetical, in which every line is marked by its initial letter. There are others, as Psalms xxv. xxxiv. xxxvii. cxlv. &c. in which the stanza only is distinguished. This was a contrivance probably intended to assist the memory, and was employed in subjects of common use, as maxims of morality and forms of devotion.

ABDALS, in the Asiatic customs, a kind of furious enthusiasts, whose madness impels them frequently to run about the streets and kill all they meet of a different religion from what they profess: this our sailors call *running a muck*, from the name of the instrument, a sort of poniard.

ABDEST, among Mahometans, a kind of washing or lotion practised both by Turks and Persians, before prayer, entering the mosque, or reading the alcoran.

ABDICATION, the act of a magistrate, who relinquishes or divests himself of an office. It differs from resignation, as this last is done in favour of some other person; whereas abdication is done without any such view. In this sense, Dioclesian is said to have *abdicated* the crown; but Philip IV. of Spain resigned it. The parliament of England voted that James II. having endeavoured to subvert the constitution of the kingdom, had abdicated the government, and that the throne was thereby vacant.

Abdication is also used by civilians, for a father's discarding his son. This, called likewise a *familia alienatio*, was different from exheredation, or disinheriting, as being done in the father's life time; whereas exheredation never took place till his death: so that an abdicated son was actually disinherited, but not *vice versa*.

Abdication, among the Romans, was also used for a citizen's renouncing his liberty, and voluntarily becoming a slave.

ABDOMEN, the lower part of the trunk of the body reaching from the thorax to the bottom of the pelvis. See Anatomy.

For diseases and wounds of the abdomen. See Medicine and Surgery.

ABDUCTION, in logic, a form of reasoning called by the Greeks *apagogue;* by which from a certain or undeniable proposition, we infer the truth of something supposed to be contained in that proposition: thus in this syllogism:

Whatever God has revealed is certainly true:
Now, God has revealed a future retribution;
Therefore a future retribution is certainly true.

In arguments of this kind, it is always necessary to prove the minor proposition to be contained in the major, or undeniable one, otherwise, the reasoning loses all its force.

ABDUCTION, in surgery, a kind of fracture, wherein the bone being entirely broken near a joint, the two stumps recede considerably from each other. See SURGERY.

ABDUCTION, in law, is the act of carrying off a woman, and marrying her against her will. (*a*)

ABDUCTOR, or ABDUCENT, in anatomy, a name given to several muscles on account of their serving to withdraw, open, or pull back the parts to which they are fixed. See ANATOMY.

ABEL TREE. See POPULUS.

ABELONIANS, a sect of heretics, called also *abelians* and *abeloites*, whose distinguishing doctrine was to marry, and yet live in professed abstinence; a tenet which, according to some authors, they founded on that text, 1 Cor. vii. 29. *Let them that have wives be as though they had none.* To perpetuate the sect, they allowed each man and woman to adopt a boy and girl, who were to be their heirs, and who were to marry under the same obligation of continence.

ABERRATION, in astronomy, an apparent motion of the celestial bodies, occasioned by the progressive motion of light, and the earth's annual advance in her orbit.

This effect may be explained by the motion of a line parallel to itself, in a way similar to the explanation of the composition and resolution of forces in *mechanics*. Let the proportion of the velocity of a ray of light, to that of the earth in her orbit, be as BC (see Plate XIV. figure 2.) to the line AC; then, by the composition of these two motions, the ray will seem to describe BA or DC, instead of its real course BC, and will appear in the direction AB, instead of its true direction CB. Therefore if AB represent a tube, carried with a parallel motion by an observer along the line AC, in the time that a particle of light would move over the space BC, the different places of the tube being AB, *ab*, *cd*, CD; and when the eye, or end of the tube, is at A, let a particle of light be supposed to enter at B; then when the tube is at *ab*, the particle will be at *e*, in the axis of the tube; and when the tube is at *cd*, the particle of light will be at *f*; and when the tube has arrived at CD, the particle will be at C, and will appear to come in the direction DC of the tube, instead of the true direction BC. Thus one particle succeeding another, forms a continued stream of light in the apparent direction DC. So that the apparent angle made by the ray of light with the line AE, is the angle DCE, instead of the true angle BCE; and the difference BCD, or ABC, is the quantity of the *aberration*.

We are indebted for this great discovery to the late Dr. Bradley, astronomer royal, who was led to it by the result of observations made with a view of determining the annual parallax of the fixed stars, or that which arises from the motion of the earth in its annual orbit about the sun. See PARALLAX.

ABERRATION *of the planets*, is equal to the geocentric motion of the planet, or the space it appears to move as seen from the earth, during the time that the light employs in passing from the planet to the earth. Thus in the sun, the aberration in longitude is constantly 20″; that being the space moved by the sun, or, which is the same thing, by the earth, in eight minutes and seven seconds, which is the time that light takes in passing from the sun to the earth. Hence the aberration of the other planets is found: for knowing the distance of the sun from the earth, it will be by common proportion, as the distance of the earth from the sun is to the distance of the planet, so is 8′ 7″, to the time of light's passing from the planet to the earth; then computing the planet's geocentric motion in this time, that will be the aberration of the planet, whether it be in longitude, latitude, right ascension, or declination.

The aberration will be greatest in the longitude, and very small in latitude, because the planets deviate very little from the plane of the ecliptic; so that the aberration in the latitude of the planets may be neglected as insensible, the greatest in Mercury being only 4″$\frac{1}{3}$, and much less in the other planets. The aberration in declination and right ascension, depend on the situation of the planet in the zodiac. The aberration in longitude, being equal to the geocentric motion, will be more or less, according as that motion may be. It will be least when the planet is stationary; and greatest in the superior planets, when they are in opposition; but in the inferior planets the aberration is greatest at the time of their superior conjunction. The maxima of aberration for the several planets, when their distance from the sun is least, are as follow:

Saturn	27′	0
Jupiter	29	8
Mars	37	8
Venus	43	2
Mercury	59	0
The Moon	0	40

Between these numbers and nothing, the aberrations of the planets in longitude vary according to their situations. But that of the sun is always 20″: the sun may, however, alter his declination by a quantity which varies from 0 to nearly 8″, being the greatest about the equinoxes, and vanishing in the solstices.

ABERRATION, in optics, a deviation of the rays of light, whereby they are prevented from meeting in the same point.

Aberrations are of two kinds; one arising from the figure of the reflecting body, the other from the different refrangibility of the rays themselves: this last is called the *Newtonian aberration*, from the name of the discoverer.

With regard to the former species of aberration, or that arising from the figure, we may observe, that if rays issue from a point at a given distance, then they will be reflected into the other focus of an ellipse, when the luminous point is in one focus; or directly from the other focus of an hyperbola, and will be variously dispersed by all other figures. If the luminous point is infinitely distant, or the incident rays parallel, then they will be reflected by a parabola into its focus. These figures being difficult to form, curved specula are commonly made spherical; the figure of which is generated by the revolution of a circular arc, which produces an aberration of all rays, whether they are parallel or not: and therefore it has no accurate geometrical focus, which is common to all rays.

ABERRATION, *crown of*, is a luminous circle about the real disk of the sun, and depending on the aberration of the solar rays, by which his apparent diameter is enlarged.

ABETTOR, or ABBETTOR, the person who promotes a crime or procures it to be committed: thus, an abettor of murder is one who commands or counsels another to

commit it. An abettor, according as he is present or absent, at the time of committing the fact, is punishable as a principal or accessory.

An abettor is the same with one who is deemed *art and part* by the law of Scotland.

ABEYANCE, Abeiance, or Abbayance, in law, the expectancy of an estate or possession: thus, when a parson dies, the fee of the glebe belonging to his church is said to be in abeyance during the time the parsonage is void.

It is a fixed principle of law, that the fee simple of all lands is in somebody, or else in abeyance.

ABHORRERS, a name given to a party in England about the 1680, in opposition to those who petitioned for a redress of grievances.

ABIB, the first month of the ecclesiastical year among the Hebrews. It was afterward called Nisan, and answered to our March.

ABIGEAT, *abigeatus*, the crime of stealing or driving off cattle in droves, otherwise called *abactus*. It was more severely punished than simple theft, *viz.* by condemnation to the mines, banishment, or even death.

ABILITY, in a law sense, is the power of doing certain actions, principally with regard to the acquisition or transfer of property. Every person is supposed to have this power, who is not disabled by any specific law.

ABJURATION, in law, is used for renouncing, disclaiming and denying the Pretender to have any manner of right to the throne of these kingdoms; and that upon oath, which is required to be taken upon divers occasions under certain pains and penalties by many statutes, particularly 1 W. and M. 13. W. III. 1 Anne. 1 Geo. I.

Abjuration, in our ancient customs, was an oath taken by a person guilty of felony, and who had fled to a place of sanctuary, to leave the world for ever. This is much the same with what in Scotland is called *signing an act of banishment.*

ABLATIVE, in Latin grammar, the name of the sixth case, which is peculiar to that language. The ablative is opposed to the dative; the latter expressing the action of giving, and the former that of taking away; thus, *ablatum est à me*, it was taken from me. It is sometimes called the comparative case, as being much used in comparing things together: thus, *dulcior melle*, sweeter than honey.

Ablative *absolute*, among Latin grammarians, is so called, because governed by no other word.

ABLECTI, in Roman antiquity, a select body of soldiers, chosen from among those called *extraordinarii.*

ABLEGMINA, in Roman antiquity, choice parts of the entrails of victims. The ablegmina were sprinkled with flour, and burnt on the altar; the priests pouring some wine on them.

ABLUENTS, diluting medicines, or such as dissolve and carry off acrimonious and stimulating matter, in any part of the body, especially the stomach and intestines.

ABLUTION, in a religious sense, a ceremony in use among the ancients, and still practised by the Mahometans; it consisted in washing the body, which was always done before sacrificing, or even entering their temples. This custom was probably derived from the Jews.

Ablution, in the church of Rome, a small quantity of wine and water, which the communicants formerly took to wash down, and promote the digestion of, the host. They also use this term for the water with which the priest washes his hands after consecrating the host.

Ablution, among chymists and apothecaries, is used for washing away the superabundant salts of any body; an operation otherwise called edulcoration.

ABOLITION, in law, denotes the repealing of any law or statute, or prohibiting some custom, ceremony, &c. sometimes also it signifies leave granted by the king, or a judge, to a criminal accuser to forbear any further prosecution.

Abolition, is also used by ancient civilians and lawyers, for desisting from, or annulling, a legal prosecution; for remitting the punishment of a crime; and for cancelling or discharging a public debt.

ABOLLA, a military garment, worn by the Greek and Roman soldiers: it was lined, or doubled, for warmth.

ABOMASUS, Abomasum, or Abomasius, in comparative anatomy, names used for the fourth stomach of ruminating beasts, or such as chew the cud. These have four stomachs, the first of which is called *venter;* the second, *reticulum;* the third, *omasus;* and the fourth, *abomasus.* It is in the abomasus of calves and lambs that the runnet is found, used for curdling milk.

ABORTION, an untimely or premature birth of a fœtus, otherwise called a miscarriage; if this happens before the second month of pregnancy, it is called a false conception.

Abortion, which is always a dangerous, and but too often a fatal accident, may be owing to a multiplicity of causes; but the most frequent ones are immoderate fluxes of any kind, violent passions of the mind, stimulating medicines, strong purges or vomits, sudden commotions of the body, as running, leaping, falls, blows, &c. to which we may add a too frequent use of venery, copious bleeding in the foot, a debility or laxity of the womb, and a plethoric habit of body: this last is often the cause of abortion in young women, pregnant of their first child.

In order therefore to prevent abortion, the above causes must be carefully guarded against. It is likewise conducive to the same end, to bleed at proper times; as also to use strengthening and attemperating medicines. It ought however to be carefully attended to, not to give any thing restringent either internally or externally, when the abortion is become unavoidable. The signs of an approaching or threatened abortion are, a sudden flaccidity of the breasts, a constriction or subsiding of the belly, a pain in the head and eyes, grinding pains in the stomach, coldness of the extremities, faintings, shiverings, &c.

As to the immediate forerunners of an abortion, they are these: violent pains in the loins and hips, a dilation of the orifice of the womb, the formation of waters, an eruption of the same, a discharge of pure blood, or blood mixed with the waters. When these symptoms appear, immediate delivery becomes absolutely necessary, without waiting for strong pains, which seldom return after the flooding is grown so excessive. This is performed in the same manner as for a timely birth. See Midwifery.

ABOU-HANNES, or Father John, the name of a bird found in Ethiopia, and supposed to be the Ibis, which the Egyptians formerly held in high veneration, but which no longer exists in that country. (a)

ABOUT, in sea language, the situation of a ship immediately after she has changed her course. *About ship*, is the order to the ship's crew for tacking.

About, in military language, expresses the movement by which a body of troops changes its front, by facing according to any given word of command.

ABRA, a silver coin in Poland, nearly equivalent to the English shilling. The abra is current through all the dominions of the grand seignior, where it passes for a fourth part of the Dutch dollar, called assani in the Levant.

ABRAHAMIANS, or ABRAHAMITES, in church history, heretics who renewed the doctrines of the Paulicians; a sect, who, to the principles of the Manichees, added an abhorrence of the cross, which they are said to have employed in the most servile offices. The term is also used for another sect, who suffered death for the worship of images.

ABRAUM, a name by which some call adamic earth, a kind of clay used by cabinet makers to give a red colour to new mahogany. It is found in the Isle of Wight, also in some parts of Germany and Italy.

ABRAXAS, a word denoting a power which presides over 365 others, the number of days in a year. It is thought to be made up of the Greek numerals A, 1; β, P, 100; A, 1; Ξ, 60; A, 1; Σ, 200: which added together make the number of 365.

ABRAXAS, a mystical term expressing the supreme God, under whom the Basilidians supposed 365 dependent deities.

It was the principle of the Gnostic hierarchy, whence sprang their multitude of æons. From abraxas proceeded the primogenial mind; from the primogenial mind, the logos, or word; from the logos, the phronesis, or prudence; from phronesis, sophia and dynamis, or wisdom and strength; from these two proceeded principalities, powers, and angels; from these other angels, to the number of 365, who were supposed to have the government of so many celestial orbs committed to their care.

ABRAXAS, among antiquaries, an antique gem or stone, with the word abraxas engraven on it. There are many kinds of them, of various figures and sizes, mostly as old as the third century. They were used as amulets, and were supposed to have great efficacy in driving away flies.

ABREAST, a sea term, expressing the situation of two or more ships, that lie in a parallel direction. When the line of battle at sea is formed *abreast*, the whole squadron advances uniformly, the ships being equally distant from and parallel to each other.

ABRIDGING, in algebra, is the reducing a compound equation to a more simple form.

This is done to save room, or to simplify the expression. Thus the equation $x^2 + \overline{a+b} \times x - \frac{ab}{c} = 0$, by putting $p = a + b$ and $q = \frac{ab}{c}$, becomes $x^2 + px - q = 0$.

ABRIDGMENT, signifies much the same with an epitome, or abstract of a large work.

The perfection of an abridgment consists in taking only what is material and substantial, and rejecting all superfluities, whether of sentiment or style. It is very seldom, however, that a good work will bear this retrenchment; and above all, the practice of *teaching* by abridgment is reprehensible. It is a practice which has unfortunately been too common in schools; and is calculated to make smatterers, and not scholars. Abridged history, for instance, can only give a dull chronology of events, without the manners, sentiments, characters, the knowledge of human nature in short, which well written history is intended to convey; and abridged geography supplies only a knowledge of the latitude and longitude, or at most of the relative situations of places, with a few charges upon the memory, the least improving parts of the study. The climate, soil, the productions, the manners of the country, its commerce and political relations, are only to be learned from larger works. But the worst effect is, that when the pupil has committed a few barren facts to memory, he concludes himself master of the science; even his curiosity is blunted, and his desire of acquiring knowledge anticipated; and the great probability is, that he never afterward is sanguine enough to open a work of real information on the subject.

ABRIDGMENT, in law, is the shortening a count or declaration: thus, in assize, a man is said to abridge his plaint, and a woman her demand in action of dower, if any land is put therein, which is not in the tenure of the defendant; for on a plea of non-tenure, in abatement of the writ, the plaintiff may leave out those lands, and pray that the tenant may answer to the remainder. The reason is, that these writs run in general, and therefore shall be good for the rest. *Cowel.*

ABROMA, in botany, a genus of the *polyadelphia dodecandria* class and order. The corolla consists of five petals larger than the calyx: and the essential character is, *pistils* 5; *capsule* five celled one valved, gaping at top; *seeds* subovate, incompletely arilled.

We know of only two species: the one *abroma angusta*, a native of New South Wales, and the Philippine isles; the other of the East Indies. The former is a tree bearing a purple flower, the other only a shrub in its native climate. With us, the abroma angusta is treated as a stove plant, and may be propagated by cuttings; the abroma Wheleri is not known in Europe.

ABRUS, in botany and the materia medica, a genus of plants of the class and order diadelphia decandria, called vulgarly the *wild liquorice*. The essential character is, the calyx obscurely four lobed, the upper lobe broadest. *Filaments* nine, united in a sheath at bottom, gaping at the back. *Stigma* blunt, *seeds* subglobose.

We know of but one species of this elegant plant, which grows wild in both Indies, Guinea and Egypt; and produces those beautiful red seeds resembling beads with a black spot or eye at the end annexed to the pod, which have been so much admired. They have been worn in many countries as ornaments. They are eaten in Egypt, but are the most unwholesome and indigestible of the pulse tribe; one variety produces white, and another yellow seeds, but otherwise they are not essentially different. The abrus is with us a stove plant, raised from seeds sown in light earth, and plunged in a hot bed. It sometimes ripens seed in England.

ABSCESS, an inflammatory tumour, containing purulent matter, pent up in a fleshy part.

Abscess is synonymous with apostem, imposthume, and imposthumation; and is always the effect of an inflammation, which frequently may be discussed without coming to a suppuration, or before an abscess is formed. See SURGERY, &c.

ABSCISSE, in conic sections, the part of the diameter of a curve line intercepted between the vertex of that

diameter, and the point where any ordinate or semi-ordinate to the diameter falls.

From this definition it is evident, that there are an infinite number of variable abscisses in the same curve, as well as an infinite number of ordinates. In the parabola, one ordinate has but one abscisse; in an ellipsis, it has two; in an hyperbola consisting of two parts, it has also two; and in curves of the second and third order, it may have three and four. In the parabola, the abscisse is a third proportional to the parameter and semi-ordinate. In the ellipsis, the square of the semi-ordinate is equal to the rectangle of the parameter into the abscisse, subtracting another rectangle of the same abscisse into a fourth proportional to the axis, the parameter, and abscisse. In the hyperbola, the squares of the semi-ordinates are to each other as the rectangles of the abscisse, into a line composed of the same abscisse and the transverse axis. See Conic Sections.

ABSCISSION, in rhetoric, a figure of speech, whereby the speaker stops short in the middle of his discourse: *e. g.* "One of her age and beauty, to be seen alone, at such an hour, with a man of his character! I need say no more."

ABSCISSION, *in surgery*, is used to express the cutting away any unsound and soft part of the body; while amputation is the cutting away of bones. See Surgery. (*a*)

ABSINTHIUM. See Artemisia.

ABSOLUTE *number*, is the known quantity which possesses one side of an equation; thus, in $x^2 + 12x = 24$, the absolute number is 24, which is equal to the square of x added to 12 times x.

Absolute *equation*, in astronomy, is the sum of the optic and eccentric equations. The apparent inequality of a planet's motion, arising from its not being equally distant from the earth at all times, is called its *optic* equation; this would subsist if the planet's real motion was uniform. The eccentric inequality is caused by the planet's motion not being uniform.

ABSOLUTELY, among divines, is used for completely, or with full power and effect, independently of any thing else: thus catholics hold that the priest forgives sins absolutely; whereas protestant divines do it only declaratively.

Absolutely, in grammar; a word is taken absolutely when it has no government: thus, in "Pray without ceasing;" the word pray is taken absolutely, as it governs nothing.

ABSOLUTION, among civilians, is used for a definitive sentence, declaring the accused person innocent, and releasing him from all further prosecution.

Absolution, among catholics, is a pretension assumed by the priests to forgive sins absolutely, that is, by virtue of a power inherent in themselves. By stat. 23 Eliz. to procure absolutions from Rome is declared to be high treason. Protestant divines pretend to no such power, but only declare the scripture terms of pardon.

Absolution, in the Scotch presbyterian church, is chiefly used for a sentence of the church judicatories, releasing a man from excommunication, and receiving him again into communion.

Absolutio *ad cautelam*, is a provisional absolution, granted to a person who has appealed from a sentence of excommunication.

ABSORBENTS, are such medicines as have the power of drying up redundant humours, whether applied to ulcers, or inwardly taken.

Absorbent *Vessels*, in anatomy, is a name indiscriminately given to the lacteals, lymphatics, and inhalent arteries. See Anatomy.

Absorbent *Vessels* is also a name used by some naturalists for the fibres of the roots of plants, which draw nourishment from the surrounding earth. See Physiology of Plants.

ABSORBING, the swallowing up or imbibing any thing: thus black bodies are said to absorb the rays of light; luxuriant branches to absorb or waste the nutritious juices, which should feed the fruit of trees, &c.

ABSORPTION, the effect of absorbing: thus we read of absorptions of the earth, when large tracts of land have been swallowed up.

Mount Vesuvius has in the course of time lost half its height; the upper part having been undermined by the fire beneath, and falling in, has been *absorbed* by the under part and the sea. In the year 1646, during the terrible earthquake in the kingdom of Chili, several whole mountains of the Andes disappeared, and were one after another wholly absorbed in the earth.

Absorption. It is a well known chymical fact, that in most cases of the combination of gaseous substances, either with other gases, or with liquids and solids, a very considerable diminution of the volume is experienced. This effect is called *absorption*.

ABSTEMII, a name given to persons who could not partake of the cup of the eucharist, on account of their natural aversion from wine.

ABSTERGENTS, medicines proper for cleansing the body from concretions and other impurities, not to be effected by simple abluents.

ABSTINENCE, the abstaining or refraining from certain enjoyments; but more especially from excessive eating and drinking; thus, it has always been a practice to abstain from a luxuriant diet at stated times, as well out of a religious view, as to confirm and preserve health.

Abstinence is highly extolled by some physicians; and that justly, when no more is meant by it than a proper regimen; but it must have bad consequences, when practised without a due regard to the constitution, age, strength, &c. of the person who uses it. There are many instances of the cure of disorders, and of protracting the term of life, by means of a strict and well regulated abstinence. Cornaro, a nobleman of Venice, after all other means had been tried in vain, recovered, and lived to the age of a hundred years, by rigid abstinence only. Many of the early Christians who retired from persecution into the deserts of Arabia, lived to a very advanced age upon bread and water only. St. Anthony lived 105 years; James the hermit 104; Arsenius 120; Epiphanius 115, &c. The records of the Tower mention a Scotsman imprisoned, and watched six weeks, during which he took no sustenance whatever; and on this account he obtained his pardon.

ABSTRACT *idea*, among logicians, the idea of some general quality or property considered simply in itself, without any respect to a particular subject; thus, magnitude, equity, &c. are abstract ideas, when we consider them as detached from any particular body or person.

It is generally allowed, that there are no objects in nature corresponding to abstract ideas; nay, some philosophers, and particularly lord Bolingbroke, dispute the existence of abstract ideas themselves, thinking it impossible for the human mind to form any such.

Abstract ideas are the same with those called universal ones; and the manner of forming them, according to modern philosophers, is this: we readily observe a resemblance among some of our particular ideas, and thus form a general notion applicable to many individuals. Thus, horses are found to resemble each other in shape, voice, and the general configuration of their parts. Now, the idea which takes in this resemblance, excluding what is peculiar to each individual, becomes of course common to this whole family or class of animals, and is therefore called a general, universal, or abstract idea.

Abstract is an epithet given to several other things, on account of their purity or universality; thus, we say abstract numbers, abstract mathematics, &c.

ABSTRACTI, a name given to a sect of Lutherans, who asserted that Christ was to be adored not only in the concrete, as the son of God, but that his flesh in the abstract was an object of adoration.

ABSTRACTION, in logic, that operation of the mind whereby it forms abstract ideas.

According to Mr. Locke, abstraction is performed three ways. First, when the mind considers any one part of a thing by itself, without attending to the whole; as the arm, leg, &c. of a man's body. Secondly, by considering the mode of a substance, without taking in the idea of the substance itself: thus, geometricians consider the properties of lines, or the length of bodies, without attending to their breadth or depth. Thirdly, by generalizing our ideas in the manner mentioned under Abstract *idea*.

This doctrine, however, of abstraction, is denied by Berkeley, bishop of Cloyne, who owns that he can imagine a man with two heads, or the upper part of a man joined to the body of a horse; "nay," adds he, "I can consider the hand, the eye, the nose, each by itself, abstracted or separate from the rest of the body; but then, whatever hand or eye I imagine, it must have some particular shape and colour; likewise the idea of a man that I frame to myself, must be either of a white or a black, or a tawny, a straight or a crooked, a tall or a low, or a middle sized man. Neither can I, by any effort of thought, conceive an absolutely abstracted idea of motion, for instance, distinct from the body moving, and which is neither swift nor slow, curvilinear nor rectilinear; and the like may be said of all abstract ideas whatsoever."

Abstraction, in chymistry, is the evaporating or drawing off, by means of heat, one part of a compound from the other. If the part abstracted is collected, it is called *distillation* or *sublimation*, according as the process is wet or dry.

ABUCCO, Abocco, or Abocchi, a weight used in the kingdom of Pegu, equal to twelve *teccalis* and a half. Two *abuccos* make an *agiro*, or *giro;* two *giri* make half a *biza*, which weighs 100 *heccalis* (2 pounds 5 ounces) the heavy weight, or 3 pounds 9 ounces light weight, of Venice. See Weight.

ABUNDANT *numbers*, those whose aliquot parts added together make more than the whole number: thus the parts of 20 make 22, *viz.* 1, 2, 4, 5, and 10.

ABYSS has been used by some philosophers, particularly Dr. Woodward, to denote a vast cavity filled with water, which they supposed, but with little argument, to exist in the centre of the earth. Conformably with this idea, it has been imagined by some writers, that there is a communication between the Caspian sea and the ocean, by means of a subterraneous abyss; and to this it is attributed that the Caspian sea does not overflow, notwithstanding the number of large rivers that run into it, of which Kempfer reckons fifty in the extent of sixty miles. But the daily evaporation is by others thought sufficient to account for this fact.

Abyss is also used for several other things, as the cavernous bowels of a mountain, or hell, or the bottomless pit, the centre of an escutcheon, a gulf, &c.

ABYSSINIAN church, that established in the empire of Abyssinia. It makes but a branch of the Cophts or Jacobites, a sect who admit only one nature in Jesus Christ.

ACACIA, in botany, a name applied, but erroneously, to several sorts of shrubs and trees. See Guilandia, Guiacum, Mimosa, Poinciena, and Spartium.

Acacia, in the materia medica of the ancients, a gum made from the Egyptian thorn, and thought to be the same as our gum-arabic.

Acacia *Germanica*, an inspissated juice, made of wild sloes, hardly ripe. The true acacia is said to be very scarce in the shops, where the German acacia is used in its stead, both being powerful astringents, and consequently good in hæmorrhages, and all kinds of fluxes.

Acacia, Akakia, a roll or bag represented on the medals of the Greek and Roman emperors; some think it is only a handkerchief, which they used as a signal; others take it for a volume, or roll of memorandums or petitions; and finally, others suppose it to be a purple bag filled with earth, to remind the prince of his mortality.

ACACIANS, the name of several sects of heretics, some of whom maintained that the Son was only of a like, not the same substance with the Father; and others, that he was not only of a distinct, but also of a dissimilar substance.

ACADEMIC, or Academician, a member of some academy.

Academics is a term more particularly used for a sect of ancient philosophers, the followers of Socrates and Plato, who maintained that all things were uncertain, and consequently that men ought to doubt of every thing. They even went so far, as to doubt whether or not they ought to doubt, it being a received maxim among them, *se nil scire, ne hoc quidem, quòd nihil sciunt.*

Of this sect, however, Cicero, who was an academic philosopher himself, gives a more favourable account. He tells us, that all the difference between the academics, and those who imagined themselves possessed of the knowledge of things, consisted in this: that the latter were fully persuaded of the truth of their opinions; whereas the former held many things to be only probable, which might very well serve to regulate their conduct, though they could not positively assert the certainty of them. "In this," says he, "we have greatly the advantage of

the dogmatists, as being more disengaged, more unbiassed, and at full liberty to determine as our judgment shall direct. But the generality of mankind, I know not how, are fond of error, and choose rather to defend with the utmost obstinacy the opinion they have once embraced, than with candour and impartiality examine which sentiments are most agreeable to truth."

ACADEMY, in Grecian antiquity, a large villa in one of the suburbs of Athens, where the sect of philosophers called Academics held their assemblies. It took its name from Academus or Ecademus, a citizen of Athens, as our modern academies take theirs from it.

Academy was also used metaphorically, to denote the sect of academic philosophers.

Academy, in a modern sense, signifies a society of learned men, established for the improvement of arts or sciences. Hence,

Academies *of antiquity*, are those designed for the illustration of whatever regards antiquity; as medals, coins, inscriptions, &c.

There are several academies of this kind in different parts of the world, as at Upsal in Sweden, at Paris, and at London. These two last are called the academy of inscriptions and belles-lettres, and the antiquarian society.

Academies *of architecture*. See Academies of Painting, *infra*.

Academies *of belles-lettres*, those chiefly designed for the cultivation of eloquence and poetry. Besides the academy of belles-lettres at Paris, and one at Caen, there are several in Italy, *viz.* one at Florence, and two at Rome.

Academies *chirurgical*, those established for the improvement of surgery.

Academies *cosmographical*, those which make geography and astronomy the chief objects of their researches. Such is that called the Argonauts, at Venice.

Academies *of dancing*. Of this kind there was one instituted by Louis XIV. with ample privileges, worthy of the nation!

Academies *ecclesiastical*, those which employ their studies in illustrating the doctrines, discipline, ceremonies, &c. that obtained in each age of the church. Such is that of Bologna.

Academies *historical*, those erected for the improvement of history. Such are those at Lisbon and Tubingen.

Academies of *languages*, those established in many parts of Europe, for refining and ascertaining the language of each country; thus the Paris academy was designed to illustrate and polish the French, that of Madrid the Spanish or Castilian, &c. But besides these, there are others in Italy, Germany, &c.

Academies of *law*: such are those of Bologna and Beryta.

Academies *medical*, those instituted with a view to promote medical knowledge and improvements. Such is that of the *Naturæ Curiosorum*, in Germany, and those of Venice, Geneva, Palermo, &c. to which some add the colleges of physicians at London and Edinburgh.

Academies *musical*; these are frequent in most parts of Europe, but more especially in France and Italy.

Academies of *painting*, *sculpture*, and *architecture*. There is one of these at Paris, and another at Rome.

The royal Academy of *arts* was instituted in London for the encouragement of *designing*, *painting*, *sculpture*, &c. in the year 1768. It has for its patron the king, and is under the direction of forty artists of the first rank in their profession. It furnishes living models to draw and paint after. Nine of the academicians are annually elected to attend and set the figures, to examine the performances of the students, and to give them the necessary instructions. The admission to this academy is free to all students qualified to reap advantage from the studies cultivated in it. There are professors of painting, architecture, anatomy, and perspective, who annually read lectures on the subjects of their several departments.

The Academy of *arts* at Petersburg was established by the empress Elizabeth. The scholars are admitted at the age of six, and continue twelve years; they are lodged, clothed, boarded, and taught at the expense of the crown. Besides this, there is the imperial academy of sciences at Petersburg, the transactions of which were formerly entitled *Commentarii Academiæ Scientiarum Imperialis Petropolitanæ*, but now are called *Nova Acta Acad. Scient. Imp. Petrop.*

Academies of *sciences*, those chiefly designed for the improvement of natural history and mathematics, with their numerous branches, botany, chymistry, mechanics, astronomy, geography, &c.

There are many other academies in different countries: as at Cortuna, for the study of Etrurian antiquities; at Florence and Milan, for painting, &c. the American, of arts and sciences; the royal Irish, &c.

Academy is also more particularly used with us for a kind of schools, where youth are instructed in various branches of learning. Of this kind we have two royal ones, *viz.* one at Portsmouth, for teaching navigation, drawing, &c. which may be called a naval or maritime academy; and another at Woolwich, where youth are taught fortification, gunnery, &c. which may be styled the military academy. Besides these, there are numerous academies, especially in London, for teaching mathematics, languages, writing, accounts, drawing, and other branches of learning. The dissenters have likewise their academies for teaching philosophy, divinity, &c. See University.

Academy *figure*, in painting, a draught or design, made after a model, with a crayon or pencil.

ACÆNA, a genus of the tetrandria monogynia class and order of plants. Its essential character is, the calyx four leaved; corolla four petalled; berry dry, inferior, one seeded, with spines bent backward. We know of only one species, the acæna elongata, which is a Mexican shrub of about two feet high.

ACAJOU, the cashew nut tree. See Anacardium.

ACALYPHA, in botany, a genus of the monoecia monodelphia class and order. The essential character is, in the male blossoms, calyx three or four leaved; corolla none; stamina eight to sixteen. In the female, calyx three leaved; corolla none; styles three; capsule three grained, three celled; seed one.

There are fourteen species of this plant, some of them annual, and resembling the broad leaved pellitory of the wall; some of them are shrubs, but none appear to have either beauty or utility to recommend their cultivation.

ACANACEOUS *plants*, those which are prickly, and bear their flowers and seeds on a kind of heads.

ACANGIS, in Turkish military affairs, the name of a kind of light armed horse.

ACANTHA, the prickles of a thorny plant.

Acantha is also used by zoologists for the spines of certain fishes, as those of the echinus marinus, &c.

ACANTHACEOUS, an epithet given to all plants of the thistle kind, on account of the prickles with which they are beset.

ACANTHOPTERYGIOUS fishes, one of the general classes or families of fishes; distinguished by having the rays of their fins bony, and some of them prickly at the extremities.

ACANTHUS, bear's breech, in botany, a genus of plants of the class and order didynamia angiospermia. The essential character is, calyx two leaved, bifid; corolla one lipped, bent down, trifid; capsules two celled. See Plate Nat. Hist. fig. 1.

There are about ten species, only four of which are exotic and tender. The acanthus mollis, or smooth leaved acanthus, is that which was formerly used in medicine, though, we apprehend, with little effect, as it seems to differ very little in its medical virtue from the altheas, and other mucilaginous vegetables. It is also the plant which is said to have afforded the hint to Callimachus for the invention of the Corinthian capital. The Gothic sculptors are supposed to have adopted for their ornament the leaves of the acanthus spinosus.

ACARUS, the tick or mite, a numerous genus of insects, of the order of aptera, or those which have no wings. The acarus has eight legs; two eyes, one on each side of the head; and two jointed tentacula. They are in general very prolific. The eggs of the cheese mite hatch in about fourteen days in summer, but in winter take more. Ninety millions of these eggs may be comprehended in the size of a pigeon's. The acarus will live seven months without food. There are thirty-five species. See Plate Nat. Hist. fig. 1—3.

ACATALECTIC, a term in ancient poetry, applicable to such verses as have all their feet and syllables, without any defect at the end. In the following lines of Horace, the first two are *acatalectic*, the last *catalectic:*

Solvitur acris, hyems, grata vice
Veris et Favoni;
Trahuntque siccas machinæ carinas.

ACATALEPSY, among ancient philosophers, the impossibility of comprehending something. The distinguishing tenet of the *pyrrhonists* was, their asserting an absolute acatalepsy with regard to every thing.

ACATERY, or Accatry, an officer of the king's household, designed to be a check between the clerks of the kitchen and the purveyors.

ACATIUM, in antiquity, a kind of boat or pinnace used in military affairs. The acatium was a species of the *naves actuariæ*.

ACAULOSE, or Acaulous (*Acaulis*) among botanists, a term used for such plants as have no *caulis*, or stem.

ACCALIA, in Roman antiquity, solemn festivals held in honour of Acca Laurentia, Romulus's nurse; they were otherwise called *Laurentalia*.

ACCAPITARE, in our old law books, the act of becoming a vassal, or paying homage to some lord. Hence

ACCAPITUM, signified the money paid by a vassal, upon such an occasion.

It is likewise used for the relief due to the chief lord. See Relief.

ACCEDAS *ad curiam*, in law, a writ lying where a man has received or fears false judgment in a hundred-court, or court-baron. It is issued out of the Chancery, and directed to the sheriff; but returnable in the King's Bench or Common Pleas. It lies also for justice delayed, and is said to be a species of the writ *Recordare*.

ACCELERATION, in mechanics, denotes the augmentation or increase of motion in accelerated bodies. The accelerated motion of falling bodies is produced by the impulse of gravity, which keeps continually acting upon them, and thereby communicates a new augmentation of motion every instant. If this increase is equal in equal times, the motion is said to be uniformly accelerated. See Mechanics.

Acceleration, in astronomy, is a term applied to the fixed stars. The *diurnal* acceleration is the time by which the stars, in one diurnal revolution, anticipate the mean diurnal revolution of the sun; that is, a star rises or sets, or passes the meridian, about 3′ 36″ sooner each day. This apparent acceleration of the stars is owing to the real retardation of the sun, which depends upon his apparent motion toward the east, and that is at the rate of 59′ $8\frac{1}{2}$″ daily: therefore to find the acceleration we say, As 360°: 59′ $8\frac{1}{2}$″ :: 24h.: 3 min. 56 sec. nearly, the acceleration required.

This acceleration serves to regulate the length and vibrations of pendulums. If, for instance, the pendulum marks 9h. 6m. when a fixed star sets or passes behind any object one day; and on the next, the eye being precisely in the same situation, the same appearance occurs at 9h. 2m. 4s. by the pendulum; it may be inferred, that such a pendulum is truly regulated, or measures time accurately.

Acceleration *of the moon*, is a term used to express the increase of the moon's mean motion from the sun, compared with the diurnal motion of the earth, which is said to be about 10″ in a hundred years. This by some is thought to be occasioned by the sun's becoming less, from the particles of light continually flowing from it, which renders the motion of the earth slower; or if the earth's by any means be increased, the motion of the moon will be accelerated. This acceleration is shown by M. La Place to arise from the action of the sun upon the moon, combined with the variation of the eccentricity of the earth's orbit.

ACCENDENTES, or Accensores, in the church of Rome, a lower rank of ministers, whose business it is to light, snuff, and trim the candles and tapers.

ACCENDONES, or Accedones, in Roman antiquity, a kind of officers in the gladiatorian schools, who excited and animated the combatants during the fight.

ACCENSI, in the Roman armies, certain supernumerary soldiers, designed to supply the place of those who should be killed, or anywise disabled. Accensi also denoted a kind of inferior officers, appointed to attend the Roman magistrates.

ACCENT, in a general sense, denotes a certain tone or manner of speaking peculiar to some nation, country, or province; thus we say, the Scotch accent, the Irish accent, &c. Among grammarians, it is the raising or lowering the voice in pronouncing certain syllables.

We have three kinds of accents, viz. the acute, the grave, and the circumflex. The acute accent, marked

thus (´), shows that the voice is to be raised in pronouncing the syllable over which it is placed. The grave accent is marked thus (`), and points out when the voice ought to be lowered. The circumflex is compounded of the other two, and marked thus (ˆ or ʌ): it denotes a quavering of the voice, between high and low.

Some call the long and short quantities of syllables accents, but erroneously. See QUANTITY.

Accents not only give a pleasing variety and beauty to the modulation of the voice, but serve to ascertain the true meaning of the word, as in *présent* and to *presént*. The Chinese are remarkable for the use they make of accents: thus the word *ya*, according to the way in which they place the accent, signifies God, a wall, an elephant, stupidity, and a goose. The Hebrew likewise abounds with them; there being no less than twenty-five tonic accents, showing the proper tone of the syllables over or under which they are placed; besides four euphonic ones, serving to render the pronunciation more sweet and agreeable. It is generally allowed, however, that the accents now in use were unknown to the ancient Hebrews.

Concerning the antiquity of the Greek accents authors are not agreed; some making them of modern date, and others contending for their having been known to the ancient Greeks.

ACCENT, in music, a certain modulation or warbling of the sounds, to express passion; either naturally by the voice, or artificially by instruments. Every bar or measure is divided into the accented and unaccented parts; the former being the emphatical, on which the spirit of the music depends. The harmony ought always to be full, and void of discords, in the accented part of the measure.

ACCENTOR, in the old music, denotes one of the three singers in parts, or the person who sung the predominant part in a trio.

ACCEPTANCE, in common law, the tacitly agreeing to some act before done by another, which might have been defeated without such acceptance. Thus if a husband and wife seized of land in right of the wife, make a joint lease of feoffment, reserving rent, and the husband dies; after which the widow receives or accepts the rent; such receipt is deemed an acceptance, confirms the lease or feoffment, and bars her from bringing the writ *cui in vita*.

ACCEPTANCE, among merchants, is the act by which the party on whom a bill of exchange is drawn, makes himself liable to the amount. An acceptance may be absolute to the bill itself at all events; or it may be partial, that is, to pay a certain part of it; or it may be conditional, that is, upon the performance of a certain condition; in which last case, when the condition is performed, the acceptance becomes absolute. An acceptance may also be collateral, as an acceptance upon protest.

An acceptance may be given either verbally or in writing; the latter, however, is the most regular and customary. But any thing tending to show that the party means to be bound by his undertaking; such as the signature of the initials, or the day of the month, keeping the bill longer than usual, or any verbal promise or agreement; will be an acceptance.

Bills payable at sight are not accepted, because they must either be paid on being presented, or else protested for want of payment. The acceptance of bills payable at a fixed day, at usance, &c. needs not be dated; because the time is reckoned from the date of the bill; but it is necessary to date the acceptance of bills payable at a certain number of days after sight, because the time does not begin to run till the next day after that acceptance. This kind of acceptance is made thus: *Accepted such a day and year*, and signed.

In general, he to whom a bill of exchange is made payable ought to demand the acceptance of the person on whom it is drawn, and that in the full extent of the terms of the bill, and on refusal of acceptance to return it with protest. This he ought to do for his own security, as well as for that of the drawer. Thus, if the bearer of a bill consents to an acceptance at twenty days sight, instead of eight days expressed in the bill, he runs the risk of the twelve days prolongation; so that he can have no remedy against the drawer, should the acceptor break in that time. Again, if a bill is drawn for three thousand pounds, and the bearer agrees to take an acceptance for two only, and should receive no more than that sum, the remaining thousand would be at the hazard of the bearer, as well as in the former case.

If, therefore, a bill is only accepted in part, or for a longer time than that expressed in it, the bearer ought to protest it, at least for the sum not accepted. Again, if the acceptor breaks, or refuses to make payment when the bill becomes due, it is necessary to get the bill immediately protested by a public notary, to be sent along with the protest to the remitter, to procure satisfaction from the drawer.

By statute, inland bills of exchange must be accepted by signing or endorsing in writing, and protested for refusal of such acceptance, otherwise the drawer is not liable to costs; it must likewise be returned to the drawer within fourteen days. Such protest, however, is not necessary, unless the value is acknowledged in the bill to be received, and unless the bill is drawn for 20l. or upward.

A bill drawn on two jointly must have a joint acceptance, otherwise be protested; but if on two or either of them, the acceptance of one is sufficient.

ACCEPTANCE, among civilians, denotes the consenting to receive something offered to us, which by our refusal could not have taken effect; or acceptance is the actual concurrence of the will of the donee, without which the donor is at liberty to revoke his gift at pleasure.

ACCEPTANCE, in the church of Rome, is particularly used for the receiving the pope's constitutions.

The acceptance of the constitution *unigenitus* has occasioned, and still continues to excite, a world of confusion in the popish countries, but more especially in France, where many of the clergy refuse to accept it.

ACCESSARY, or ACCESSORY, in law, a person who is in anywise aiding in the commission of some felonious action.

By statute, he who counsels, abets, or conceals, the committing of such an action, or the person who has committed it, is deemed an accessory.

There are two kinds of accessories, *viz.* before the fact, and after it. The first is he who commands or procures another to commit felony, but is absent when it is done; for if he is present, he is a principal. The accessory after the fact is one who receives, comforts, or assists, the felon; knowing him to be such.

In the highest crimes, as high treason, &c. and the lowest, as riots, forcible entries, &c. there are no accessories, but all concerned are principals.

It is a maxim among lawyers, that where there is no principal, there can be no accessory; so that it is necessary the principal be first convicted, before the accessories can be arraigned. If, however, the principal cannot be taken, the accessory may be prosecuted for a misdemeanor, and punished by fine, imprisonment, &c. Accessories in petty treason, murder, and felony, are not allowed their clergy.

A wife may assist her husband, without being deemed accessory to his crime; but not *e contra*. A servant assisting his master to escape, is reckoned an accessory; also furnishing others with weapons, or lending them money, &c. will make persons accessories. Persons buying or receiving stolen goods, knowing them to be such, are deemed accessories to the felony. Also if the owner of stolen goods, after complaint made to a justice, takes back his goods, and consents to the escape of the felon, he becomes accessory after the fact.

ACCESSION, a term of various import; thus among civilians, it is used for the property acquired in such things as are connected with or appendages of other things; among physicians, it signifies the same with what is more usually called paroxysm; among politicians, it is used for a prince's agreeing to and becoming a party in a treaty before concluded between other potentates, or it more particularly denotes a prince's coming to the throne by the death of the preceding king; and lastly, it is used by Romanists for a peculiar way of electing a pope, which is, when one candidate has got two thirds of the votes, the rest are enrolled by accession.

ACCESSORY *nerves*, or *par* Accessorium, a pair of nerves of the neck: which arising from the spinal marrow in the vertebræ of the neck, enters the cranium by the great foramen in the os occipitis. Here it is joined by the par vagum, and coming out of the cranium again by the same aperture, it recedes from the par vagum, and is bent back to the trapezius, a muscle of the shoulder. See Anatomy.

ACCIACATURA, is a term in music, which denotes the putting down with any interval the half note below it, and instantly taking off the finger which has struck the lowest of the two notes, continuing the sound of the other note till the harmony is changed.

ACCIDENS, *per*, is used to denote what does *not* follow from the nature of a thing, but from some accidental qualities of it, in which sense it stands opposed to *per se*, which denotes the nature and essence of a thing; thus fire is said to burn *per se;* but a piece of iron made hot, only burns *per accidens*, by a quality accidental to it.

ACCIDENT, among logicians, is used in a threefold sense. 1. Whatever does not essentially belong to a thing, as the clothes a man wears, or the money in his pocket. 2. Such properties in any subject as are not essential to it; thus whiteness in paper is an accidental quality. 3. In opposition to substance, all qualities whatever are called accidents, as sweetness, softness, &c.

Accident *absolute* is used by the Romish church for an accident which may possibly subsist, at least miraculously, without any subject; an absurdity which has been strenuously maintained by many of their casuists, and even solemnly decreed by some of their councils.

Accident, in heraldry, an additional note or mark, in a coat of arms, which may be either omitted or retained, without altering the essence of the armour.

ACCIDENTAL, in philosophy, is applied to that effect which proceeds from a cause occurring by *accident*, without being subject to general laws or regular returns. In this sense accidental is opposed to constant. The sun's greater or less altitude is the *constant* and chief cause of the heat in summer and cold in winter; but wind, snow, or rain, are accidental causes.

Accidental *colours*, are those which depend upon the affections of the eye, in contradistinction to such as belong to the light itself. The impressions made on the eye by looking steadfastly on objects of a particular colour, frequently give a false colouring to other objects which are viewed during their continuance.

Accidental *point*, in perspective, that point in the horizontal line, where all lines parallel among themselves meet the perspective plain. See Perspective.

Accidental, in music, is an epithet added to such sharps, flats, and naturals, as do not occur in the clef, and which imply some change of key or modulation different from that in which the piece began.

ACCIPENSER, in ichthyology, a genus of fishes, belonging to the order of nantes, and class of amphibia, in the Linnæan system. The accipenser has a single linear nostril: the mouth is in the under part of the head, and contains no teeth; the cirri are below the snout, and before the mouth. There are three species of this genus, *viz.*

1. Accipenser Huso has four cirri; the body is naked, *i.e.* has no prickles or protuberances. The skin of the huso is so tough and strong, that it is employed to draw carts and other wheel carriages; and the ichthyocollo, or isinglass of the shops, is made from its sound or scales. The huso is the largest of the genus, and grows to 24 feet in length. It inhabits the Danube and the rivers of Russia.

2. Accipenser Ruthenus has four cirri, and fifteen squamous protuberances. It is a native of Russia.

3. Accipenser Sturio, or the sturgeon, has four cirri, and 11 squamous protuberances on the back. This fish annually ascends our rivers, but in no great numbers, and is taken by accident in the salmon nets. It seems a spiritless fish, making no manner of resistance when entangled, but is drawn out of the water like a lifeless lump. It is seldom taken far out at sea, but frequents such parts as are not remote from the æstuaries of great rivers. It is admired for the delicacy and firmness of its flesh, which is white as veal, and extremely good when roasted. It is generally pickled. The greater part of what we receive comes either from the Baltic rivers or North America. Great numbers are taken during summer in the slake Frischehaff, and Curisch-haff near Pillau, in large nets made of small cord. The adjacent shores are formed into districts, and farmed out to companies of fishermen, some of which are rented for 6000 guilders, or near 300*l.* *per annum*. They are found in vast abundance in the American rivers in May, June, and July; at which time they leap some yards out of the water, and, falling on their

sides, make a noise to be heard in still water at an immense distance. Caviare is made of the rows of this, and also of all the other sturgeons, dried, salted, and packed up close. Isinglass is likewise made of the sound of this fish, but in very small quantities. The sturgeon grows to the length of 18 feet, and the weight of 700 pounds; but it is seldom taken in our rivers of that bulk. In the manner of breeding, this fish is an exception among the cartilaginous kind; being, like the bony fish, oviparous, and spawning in water. See Plate Nat. Hist. fig. 4—6.

ACCIPITRES, the name of a whole order of birds, the distinguishing characteristic of which is, that they have a hooked or crooked beak.

This order comprehends four genera, *viz.* the vulture, falco, strix, and lanius kinds; and 72 species.

ACCLAMATION, in Roman antiquity, a shout raised by the people to testify their applause, or approbation of their princes, generals, &c. Such is that of Ovid, Fast. I. 613. *Augeat imperium nostri ducis, augeat annos.*

The acclamations of the theatres, which were at first confused and tumultuous shouts, became in process of time a kind of regular concerts. When Nero played in the theatre, a signal was given, and upon this 5000 soldiers began to chaunt his praise, which the spectators were obliged to repeat. The honour of acclamations was chiefly bestowed on the emperors; but sometimes it was conferred on their children and favourites, and on magistrates who presided at their games.

The Greeks were accustomed to practise acclamation, an instance of which is mentioned by Plutarch, in consequence of Flaminius's restoring liberty to Greece, when the shouts were so loud, that it was hyperbolically said, the birds fell from the sky with the noise.

Acclamations which were at first practised in the theatre, passed to the senate, and other departments of civil society, and were at length admitted into the acts of councils, and the ordinary assemblies of the church. Chrysostom checked acclamations of this kind, but Augustin received them very willingly. Sermons were applauded with hands and feet, by leaping up and down, and exclaiming "orthodox," and by shaking the loose garments, and waving handkerchiefs. These were some of the ancient forms of acclamation: of the Hebrews, "Hosanna;" of the Greeks, Αγαθη Τυχη, good luck; of the Romans, *Dii te nobis servent*, may the Gods preserve you! To the disgrace of the famous French convention in 1792, it may be added, decrees were voted in a legislative assembly, not upon discussion, but "by acclamation."

Acclamation *medals*, among antiquaries, those whereon the people are represented as expressing their joy by acclamation.

ACCOLADE, in ancient customs, the ceremony of conferring knighthood, by the king's laying his arms about the young knight's neck, and embracing him.

ACOLLE'E, in heraldry, a term used in different senses; sometimes it denotes the same with accolade; sometimes two things joined together; at other times, animals with collars, or crowns about their necks; and finally, battons, or swords placed saltierwise behind the shield.

ACCOMMODATION, or Accommodating, in geometry, is the fitting a line or figure into a circle, &c. agreeably to the conditions of the problem; and in philosophy, is the application of one thing by analogy to another.

ACCOMPANIMENT, in music, is used for the instruments which accompany a voice, to make the music more full. Among the moderns, the accompaniment frequently plays a different part or melody, from the song it accompanies; but authors are not agreed, whether or not it was so among the ancients.

Accompaniment, in heraldry, denotes any thing added to a shield by way of ornament, as the belt, mantling, supporters, &c. It is also used for several bearings about a principal one; as a saltier, bend, fess, &c.

ACCOMPLICE, in law, a person who is privy to, or aiding in, the perpetration of some crime. It is generally applied to such accessories as are admitted to give evidence against fellow criminals. By the law of Scotland, accomplices cannot be prosecuted till the principal offenders are convicted.

ACCORD, in music, the same with what is more usually called concord. See Concord. It is sometimes used for chord.

Accord, in law, a verbal agreement between two or more, where any one is injured by a trespass, or other offence committed, to make satisfaction to the injured party; who, after the accord is performed, will be barred in law from bringing any new action against the aggressor for the same trespass. It is safest, however, in pleading, to allege satisfaction, and not the accord alone; because in this latter case, a precise execution in every part must be alleged; whereas, in the former, the defendant needs only say, that he paid the plaintiff such a sum in full satisfaction of the accord which he received.

ACCOUNT, or Accompt, in a general sense, is used for all arithmetical computations, whether of time, weight, measure, money, &c. Account is also used collectively, for the books in which merchants, traders, and bankers enter all their business, traffic, and bargains with each other. See Book-keeping.

Account, in law, is a writ or action, which lies against a person, who, because of his office, or business, is obliged to render an account to another, but refuses to do it; as a bailiff, for instance to his lord. It is now seldom used.

Accounts, *Chamber of*, in the ancient French polity, a sovereign court, answering nearly to our exchequer.

ACCOUNTANT *general*, in the court of chancery, an officer appointed by act of parliament to receive all monies lodged in court, and convey the same to the bank of England for better security. The salary of this officer and his clerks is to be paid out of the interest made of part of the money; it not being allowable to take fees in this office.

ACCOUNTS, *public, commissioners of*, are commissioners appointed, with handsome salaries, to examine and state in what manner, and at what times, the receipts, issues, and expenditures of the public monies are accounted for; and to consider and report, by what means and methods the public accounts may in future be passed, and the accountants compelled to pay the balances due from them, in a more expeditious, effectual, and less expensive manner.

ACCRETION, in natural history, the increase or growth of a body by an external addition of new parts; thus it is salts, shells, stones, &c. are formed.

ACCRETION, among civilians, a term used for the property acquired in a vague or not occupied thing, by its adhering to or following another thing already occupied; thus, if a legacy is left to two persons, and one of them dies before the testator, the legacy devolves to the survivor by right of accretion. Alluvion is another instance of accretion.

ACCROCHE', in heraldry, denotes one thing being hooked into another.

ACCRUED, in heraldry, a term applied to a tree full blown.

ACCUBATION, the posture used among the Greeks and Romans at table: which was with the body extended on a couch, and the head resting on a pillow, or on the elbow supported by a pillow.

Pitiscus tells us the manner in which the guests were disposed, which was this: a low round table was placed in the dining room, about which stood sometimes two, but more usually three beds or couches; from the number whereof the dining room got the name of *biclinium* or *triclinium*. These couches were covered with richer or plainer cloths, according to the quality of the person, and furnished with quilts and pillows. Each couch usually contained three persons; it being deemed sordid to crowd more. The first lay at the head of the bed, with his legs extended behind the second, who lay in the same manner to the third. The middle place passed for the most honourable. However, before placing themselves, they always took care to pull off their shoes, and put on what was called the *vestis cœnatoria*, or the dining garment.

ACCUMULATION, among lawyers, denotes the concurrence of several titles to the same thing, or of several circumstances or proofs to make out one fact.

ACCUMULATION OF DEGREES, in an university, the taking several of them together, or at smaller distances from each other than usual, or than the rules allow of.

ACCUSATION, among civilians, the bringing a criminal action against any person. The ancient Roman lawyers distinguished between postulatio, delatio, and accusatio. For, first, leave was desired to bring a charge against one, which was called postulare: then he against whom the charge was laid, was brought before the judge; which was called deferre, or nominis delatio: lastly, the charge was drawn up and presented, which was properly the accusatio. The accusatio properly commenced, according to Pædianus, when the reus or party charged, being interrogated, denied he was guilty of the crime, and subscribed his name to the delatio made by his opponent. In England, by Magna Charta, no man shall be imprisoned or condemned on any accusation, without trial by his peers, or the law; none shall be vexed with any accusation, but according to the law of the land; and no man may be molested by petition to the king, &c. unless it be by indictment or presentment of lawful men, or by process at common law. Promoters of accusations are to find surety to pursue them; and if they do not make them good, shall pay damages to the party accused, and also a fine to the king. No person is obliged to answer upon oath to a question whereby he may accuse himself of any crime.

ACCUSATIVE, among Latin grammarians, the fourth case, which is always governed by an active verb or preposition, expressed or understood; thus, *amo Deum*, I love God; *eo Londinum, i.e. eo ad vel versus Londinum*, I am going to London, or I am on my way to London. In the English noun there is no difference between the nominative and accusative, except that the *former* precedes and the *latter* follows the verb.

ACER, the maple tree in botany. It is of the class and order polygamia monoecia. The essential character is, calyx five cleft; corolla five petalled; stamina eight or ten; germen two, or three, superior; stylus simple; capsule two, sometimes three, with one seed in each terminated by a wing. The male blossoms are without germen or stylus.

The maple genus consists entirely of trees, and embraces twenty species. The acer pseudoplatanus or great maple, vulgarly called the sycamore tree, or mock plane, and in Scotland the plane tree, is too well known to require a description. Before earthen ware came into common use, the wood of this tree was in great request for trenchers; and it is still much used by the turners for bowls, dishes, &c. It is of quick growth, but not of long duration. In spring and autumn the wounded stem of this tree will, like the birch, pour forth a saccharine juice, from which wine may be made. There are two varieties in the nurseries, one with very broad leaves, the other variegated; both very ornamental for large plantations.

The acer campestre is also well known, growing very commonly in our woods and hedges. It is much cultivated in some parts of the kingdom for hop poles. The *scarlet* maple is also propagated with us for its beautiful scarlet flowers.

The acer saccharinum, or American sugar maple, however, is perhaps the most distinguished of the tribe. It grows to the height of forty feet; and large tracts in North America are covered with it. The sugar is procured by tapping, or wounding, the tree with an augur about the months of February, March, or April, when the sap is rising; and from 23 gallons one quart of sap drawn from two trees in twenty-four hours, 4 pounds 13 ounces of sugar have been obtained; and in some cases one pound of sugar from every 3 gallons of sap. The sugar thus obtained is grained, clayed, and refined in every respect as that from the cane in the West Indies, and is of a very excellent quality. There is no doubt that it might be cultivated with great advantage in this country; since the Indians of Canada have practised the making of sugar from the maple, time out of mind, even in that ungenial climate.

ACERRA, in antiquity, a kind of altar erected near the bed of a dead person, on which incense and other perfumes were burnt till the time of the burial.

ACERRÆ also denoted the pots wherein the incense was burnt; hence we read of *plena acerra*, a full acerra.

ACETABULUM, in antiquity, a kind of utensil wherein sauce was served to table, and not unlike our salts or vinegar cruets.

ACETABULUM was also a Roman measure, used as well for dry things as liquids; and equal to a cyathus and a half.

ACETABULUM, in anatomy, a hollow cavity in the heads of certain bones serving to receive the protuberant heads of others, and forming the articulation called enarthrosis. See ANATOMY.

AC-ETIAM, in law, a clause devised by the officers of the king's bench, and added to the usual complaint of trespass. This is done in some cases to save the suitors the trouble and expense of suing out special originals.

ACETIC ACID differs from acetous acid, by having a larger proportion of oxygen. See ACETOUS ACID and CHYMISTRY.

ACETITE *of Potash*. This salt occurs native in the sap, and some other vegetable juices, and also in the urine of quadrupeds. It is prepared artificially by adding carbonate of potash to distilled vinegar, till the liquor contains a slight excess of acid; if the salt is wanted in a solid state, it may be obtained by evaporation. It has a strong affinity for water, and deliquates readily in the air. For this and the other acetites, see CHYMISTRY.

ACETOUS ACID, a transparent colourless fluid, obtained from distilled vinegar, in the proportion of 7 or 8 per cent. to the distilled vinegar. See CHYMISTRY. This acid forms an important article in the materia medica. Common vinegar, which is this acid in an impure state, is also much used in food, and for the preservation of animal and vegetable substances.

ACETUM *rosatum*, vinegar of roses, is made of rose buds infused in vinegar five or six weeks; the roses are then pressed out, and the vinegar preserved. It is used in cases of headache.

ACETUM *prophylacticum*, is a preparation of acetic acid, camphor, flower of lavender, &c. It is called also the *vinegar of the four thieves*, who during the plague at Marseilles plundered the sick, the dying, and the dead, and escaped unhurt by the use of this preparation.

ACHALALACTLI. See ALCEDO.

ACHANE, in Persian antiquity, a corn measure equal to forty-five attic medimni.

ACHANIA, a genus of the monodelphia polyandria class, and the natural order of columniferæ. The essential character is, calyx double; outer many leaved; corolla convolute, berry five seeded.

The achania genus includes three species, all exotics, and cultivated, chiefly from cuttings, as stove plants.

ACHERNER, a star of the first magnitude, in the southern extremity of the constellation Eridanus; invisible in our latitude. See ERIDANUS.

ACHERSET, an old English measure of corn, probably the same with our quarter, or eight bushels; the monks of Peterborough had, among other things, an allowance of 12 *achersotes de frumento*.

ACHIAR, a Malayan word, signifying a mixture of all sorts of fruits and roots, pickled with vinegar and spice. The Dutch import this pickle from Batavia.

ACHILLEA, a genus of plants comprehending the millefolium and ptarmica of Tournefort. It is of the class and order syngenesia polygamia superflua. The corolla is compound radiate: and the essential character is, calyx ovate, imbricate; florets of the ray about four; down none; recept. chaffy.

It includes twenty-seven species, most of them hardy, though natives of the south of Europe, only two being indigenous here. The achillea ptarmica, or sneezewort, is of this description. It is used in medicine as a sternutatory; and in Siberia in decoction, to stop hæmorrhages. A beautiful double variety is cultivated in our gardens, under the name of white bachelors' buttons. The other English milfoil is the yarrow, well known in our meadows. This has also by some been recommended in hæmorrhages, dysenteries, &c.

ACHILLES, an appellation sometimes given to the principal argument made use of by each sect of ancient philosophers, in defence of their system. It has obtained this name in allusion to the strength of Achilles; and is particularly used for Zeno's argument against motion, which consisted in making a comparison between the swiftness of Achilles and the slowness of a tortoise; whence he inferred that a slow body, if but ever so small a distance before a swift one, could never be overtaken by it.

ACHILLES, *tendon of*. See ANATOMY.

ACHIMBASSI, the name of an officer who presides over the practice of medicine at Cairo.

ACHIROPOETOS, in church history, a name given to certain pictures of Christ, supposed to have been painted in a miraculous manner.

ACHOR, a kind of running ulcer on the face, chiefly infesting children, but sometimes also grown persons.

ACHRAS, the wild pear tree, a genus of plants of the class and order hexandria monogynia, the flower of which consists of five erect petals, of a cordated shape; and the fruit is an oval berry divided into ten cells. The essential character is, calyx six leaved; corolla ovate, sexfid, with six scales alternate, more within; pome celled; seeds solitary. There are four species, and they are called mammee, sapoti, and bully tree. They are all natives of the West-Indies, where the fruit is eaten.

ACHROMATIC, a term used to denote telescopes contrived to remedy the aberration in colours. See OPTICS.

ACHTELING, a measure for liquids used in Germany.

ACHYRANTHES, a genus of the pentandria monogynia class of plants, belonging to the natural order of misal laneæ, Linn. The characters are; the calyx is a double perianthium; the exterior one consisting of three lanced acute leaves, which are persistent; the interior of five leaves, also persistent. No corolla; the nectarium is five valved, surrounding the germen, bearded at the top, concave, and falling off. The stamina consist of five filaments the length of the corolla; the antheræ are ovate and incumbent. The pistillum has a top shaped germen; the stylus is filiform, and the length of the stamina; the stigma is villous, and divided into two segments. The perianthium is a roundish one celled capsule, not gaping. The seed is single and oblong. Of this genus eleven species are enumerated; but the character of the genus does not agree in them all. They are all natives of the Indies. Only one of them, the altissima, is commonly cultivated in botanic gardens, and that more for the sake of variety than beauty. It grows to the height of three feet, with oblong pointed leaves. The flowers come out in long spikes, from the extremities of the branches, and appear in July, the seeds ripening in September. Plants of this kind must be reared in a hotbed, and may be transplanted, when they have acquired sufficient strength. If kept in pots, and sheltered during the winter in a warm greenhouse, they will live two or three years.

ACIA, a genus of the monadelphia dodecandria class and order, and natural order of pomaceæ. The essential character is, calyx five parted; corolla five petalled, unequal; drupe full of chinks. We know of only one species,

a native of Guiana, which rises to a tree of sixty feet in height. The fruit is eaten by the Creoles, and accounted pleasant.

ACICULÆ, certain small spikes, or prickles, in form of needles, wherewith nature has armed several animals, as the hedgehog, *echinus marinus*, &c.

ACID, in chymistry. The word acid, originally synonymous with sour, and applied only to bodies distinguished by that taste, has been gradually extended in its signification by chymists, and now comprehends under it all substances possessed of the following properties:

1. When applied to the tongue, they excite that sensation which is called *sour* or *acid*.

2. They change the blue colours of vegetables to a red. The vegetable blues employed for this purpose are generally tincture of litmus and syrup of violets or radishes, which have obtained the name of *re-agents* or *tests*. If these colours have been previously converted to a *green* by alkalies, the acids restore them again.

3. They unite with water in almost any proportion.

4. They combine with all the alkalies, and most of the metallic oxides and earths, and form with them those compounds which are called *neutral salts*.

It must be remarked, however, that every acid does not possess all these properties, but they all possess a sufficient number by which they may be distinguished from other substances.

The acids are by far the most important class of bodies in chymistry. It was by their means indeed, by studying their properties, and by employing them as instruments in the examination of other bodies, that men of science laid the foundation of chymistry, and brought it to that state in which we find it at present. The nature and composition of acids, therefore, became a very important point of discussion, and occupied the attention of the most eminent cultivators of the science.

Paracelsus believed that there was only one acid principle in nature, which communicated taste and solubility to the bodies in which it was combined. Beccher embraced the same opinion; and added to it, that this acid principle was a compound of earth and water, which he considered as two elements. Stahl adopted the theory of Beccher, and endeavoured to prove that this acid principle is sulphuric acid; of which, according to him, all the other acids are mere compounds. But his arguments were only conjectures or vague experiments, from which nothing could be deduced. Nevertheless, his opinion, like every other which he advanced in chymistry, continued to have supporters for a long time, and was even countenanced by Macquer. At last its defects began to be perceived: Bergmann and Scheele declared openly against it: and their discoveries, together with those of Lavoisier, demonstrated the falsehood of both parts of the theory, by showing that sulphuric acid does not exist in the other acids; and that it is not composed of water and earth, but of sulphur and oxygen.

The opinion, however, that acidity is owing to some principle common to all the salts, was not abandoned. Wallerius, Meyer, and Sage, had advanced different theories in succession about the nature of this principle; but as they were founded rather on conjecture and analogy than direct proof, they obtained but few advocates. At last Mr. Lavoisier, by a number of ingenious and accurate experiments, proved that several combustible substances when united with oxygen form acids; that a great number of acids contain oxygen; and that when this principle is separated from them, they lose their acid properties. Thus phosphorus, charcoal, and sulphur, being separately inflamed in oxygen gas, combine with its base; acquire an additional weight, equivalent to that of the air consumed, or absorbed; and are converted into phosphoric, carbonic, and sulphuric acids.

The Lavoiserian theory is further supported by experiments, in which the known acids are decomposed into oxygen and one or more combustible bases. If purified nitre (nitrat of potash,) previously deprived of its water of crystallization, is exposed in a silver retort to a low red heat, a large quantity of gas, consisting of oxygen and azote, in the proportion of four of the former to one of the latter, will be given out, and pure potash will remain in the retort; the weight of which, with that of the gases, will be equivalent to that of the original nitre. But force the gases into union, by means of the electric spark, their volume is gradually diminished, and at length the whole is reduced to an acid liquor, possessing all the qualities of nitrous acid; if this, and the potash remaining in the first process, are mixed together, chymical union immediately ensues, and nitre is reproduced. He concluded, therefore, that the acidifying principle is oxygen, and that acids are nothing but combustible substances combined with oxygen, and differing from one another according to the nature of the combustible base.

This conclusion, as far as regards the greater number of acids, is certainly true. All the simple combustibles, except hydrogen, are convertible into acids; and these acids are composed of oxygen and the combustible body combined. This is the case also with four of the metals. It must not, however, be admitted without some limitation.

1. When it is said that oxygen is the acidifying principle, it is not meant to affirm that oxygen possesses the properties of an acid, which would be contrary to truth; all that can be meant is, that it enters as a component part into acids, or that acids contain it as an essential ingredient.

2. But, even in this sense, the assertion cannot be admitted: for it is not true that oxygen is an essential ingredient in all acids, or that no body possesses the properties of an acid unless it contains oxygen. Sulphurated hydrogen, for instance, possesses all the characters of an acid, yet it contains no oxygen.

3. When it is said that oxygen is the acidifying principle, it cannot be meant to affirm that the combination of oxygen with bodies produces in all cases an acid, or that whenever a body is combined with oxygen the product is an acid; for the contrary is known to every chymist. Hydrogen, for instance, when combined with oxygen, forms not an acid, but pure water, and the greater number of metallic bodies form only oxides.

All that can be meant, then, when it is said that oxygen is the acidifying principle, is merely that it exists as a component part in the greater number of acids; and that many acids are formed by combustion, or by some equivalent process. The truth is, that the class of acids is altogether arbitrary; formed when the greater number of the bodies arranged under it were unknown, and before

any precise notion of what ought to constitute the characteristic marks of an acid had been thought of. New bodies, when they were discovered, if they possessed any properties analogous to the known acids, were referred without scruple to the same class, how much soever they differed from them in other particulars. Hence we find, under the head of acids, bodies which have scarcely a single property in common, except that of combining with alkalies and earths.

From what has been stated, however, it follows, that the acids are compound bodies, and almost all of them formed by the union of some other substance with oxygen: this substance is called the base or radical. In some cases the radical has never been found in a separate state, when it is said to be *unknown*. See ACIDIFIABLE *base*.

The acids as combined with oxygen may be arranged as follows:

States of Oxygenation, according as the compound contains less or more oxygen.

Bases.		1st.	2d.	3d.
With simple radicals.	Sulphur	Sulphureous	Sulphuric	
	Azote	Nitrous	Nitric	
	Phosphorus	Phosphoreous	Phosphoric	
	Carbon		Carbonic	
	Arsenic	Arsenious	Arsenic	
	Molybdena		Molybdic	
	Chrome		Chromic	
With double radicals.	Carbon and hydrogen in different proportions.	Acetous	Acetic	
			Tartaric	
			Citric	
			Oxalic	
			Malic	
			Gallic	
			Benzoic	
			Succinic	
			Saccholactic	
			Formic	
			Sebacic	
			Prussic	
With triple radicals.	Carbon, Hydrogen, and Azote.		Lithic	
With unknown radicals.			Muriatic	Oxymuriatic
			Fluoric	
			Boracic	

See CHYMISTRY.

ACIDIFIABLE *base*, or RADICAL, is any substance, whether simple or compound, that is capable of uniting, without decomposition, with such a quantity of oxygen as to become possessed of acid properties. Almost all the acids agree with each other in containing oxygen, but they differ in their radicals; of course the acidifiable base or radical determines the species of acid. Sulphur combined with oxygen, forms sulphuric or vitriolic acid. Almost all substances will combine with oxygen, but they are not all acidifiable bases. That the process of acidification may take place, a large proportion of oxygen is necessary, otherwise the result is only an oxyd. See CHYMISTRY.

ACIDOTUM, a genus of the monoecia polyandria class and order. The essential character is: male, calyx five leaved; corolla none; stamina fixed to a globular receptacle. Female, calyx six leaved; corolla none; style trifid; capsule three grained. One species only is noted of this plant, which is a native of Jamaica. But of its qualities little seems to be known.

ACIDULÆ, a term used for the cold mineral waters, distinguished by their sparkling appearance when poured from one vessel to another, and by their brisk acidulous taste. They contain a considerable quantity of free carbonic acid.

ACIDULUM, a term to express a kind of native compound salts, in which the alkaline base is supersaturated with acid; these are employed in chymical processes, and for economical purposes as acids. The two species already known are, the tartareous acidulum or acidulous tartrite of potash; and the oxalic acidulum, or acidulous oxalat of potash.

ACINACES, a kind of cutlass, or cimeter, in use among the Persians.

ACINUS, a name given to grapes or berries growing in clusters, in opposition to baccæ, or such berries as grow single.

ACKLYS, in medicine, signifying dimness of sight, or blindness, arising from opacity of the cornea. (*a*)

ACLIDES, in Roman antiquity, a kind of missive weapon, with a thong fixed to it, whereby it might be drawn back again.

Most authors describe the aclides, as a sort of dart or javelin; but Scaliger makes it roundish, or globular, with a wooden stem to poise it by.

ACNIDA, Virginian hemp, a genus of the dioecia class, and pentandria order of plants. The characters are; in the male, the calyx is a perianthium consisting of five leaves, ovate, concave, acute, and membranous on the margin. No corolla. The stamina consist of five very short capillary filaments; the antheræ are versatile, two celled, and forked at both ends. Female on a separate plant, of which the calyx consists of an involucrum many leaved, linear, and deciduous; and a perianthium two leaved, very small and persistent. No corolla. The pistillum has an ovate germen; the styli are five, long, reflected, and downy; the stigmata are simple. The pericarpium is an egg shaped fruit, compressed, many angled, sulcated, and covered with a succulent calyx. The seed is solitary, round, and compressed. There is only one species of it, *viz.* the acnida cannibina. It is a native of Virginia, but rarely cultivated in Europe, except for the sake of variety. It has little beauty, and at present is applied to no useful purpose.

ACNUA, a measure of land, among the ancient Romans, containing about a quarter of an acre.

ACOEMETI, a kind of ancient monks, who performed divine worship night and day in their churches. They divided themselves into three classes, each of which officiated in their turn, and relieved others, so that their churches were never silent, night or day.

ACOLUTHI, or ACOLYTHI, denote candidates for the ministry, so called from their continually attending the bishop. It is a term applied to persons who are steadfast and immoveable in their resolutions.

ACOLUTHI, is used for the body guards who attended the emperors of Constantinople.

ACOLUTHI, is also an appellation given to the stoics, on account of their steady adherence to what they had once resolved.

ACOLYTHIA, in the Greek church, denotes either the order of divine service, or the book containing it.

ACON, an instrument used in ancient exercises, like the dircus; a name likewise given to an ancient order of knighthood.

ACONITI, an appellation given to some of the ancient *athletæ*, who anointed their bodies with oil, instead of covering them with dust; or who overcame their antagonists with ease.

ACONITON, signifies not plastered, and is a name applied to vessels not lined within.

ACONITUM, wolfsbane, or monks-hood, a genus of plants of the class and order polyandria trigynia. The essential character is, calyx none; petals five, the highest arched; nectaries two, peduncled, recurved; capsules three or five.

Nine species, all hardy herbaceous perennials, are enumerated of this genus, which has received the name of monks-hood from its flower, being composed of five irregular petals, resembling in some measure a man's head with a helmet or hood on it. The upper petal represents the hood or helmet; the two lower ones stand for that part which covers the lower jaw; and the two wings seem adapted for covering the temples. From the centre of the flower there arise two pistils, resembling feet, and received into the hollow of the upper petal, or hood; as is also another pistil, which finally becomes a fruit, composed of several membranaceous vaginæ collected into a head, and usually containing angular and wrinkled seeds.

All the species of aconite are extremely acrimonious, occasioning mortal convulsions, or inflammations that end in a mortification. It is even said that some persons by only smelling at the flower of the common monks-hood have been seized with swooning fits, and lost their sight for two or three days. Like other poisons, however, it has been used as a medicine in small doses, particularly in rheumatisms and intermittents.

Acontias is used for a kind of meteor, with a roundish or oblong head, and a long slender tail, resembling a javelin.

ACONTIUM, in Grecian antiquity, a kind of dart or javelin, resembling the Roman pilum.

ACORN, a little ornamental piece of wood, in the shape of a cone, fixed on the top of the spindle on the mast head, above the vane, to keep it from coming off the spindle in a whirlwind.

ACORUS, *calamus, aromaticus, sweet flag*, or *sweet rush*, a genus of the monogynia order, belonging to the hexandria class of plants, and ranking in the second natural order, piperitæ. The characters are, the calyx is a cylindric simple spadix covered with florets; there is no spatha, nor perianthium; the corolla is composed of six obtuse, concave, loose petals; the stamina consist of six thickish filaments, somewhat longer than the corolla; the antheræ are thickish and didymous; the pistillum has a gibbous oblong germen the length of the stamina, no stylus, the stigma a prominent point; the pericarpium is a short triangular, obtuse three celled capsule, attenuated at both ends; the seeds are numerous, and of an oblong egg shape. There are two species: the acoros calamus grows naturally in shallow standing waters, and is found wild in rivulets and marshy places about Norwich and other places in this island, in the canals of Holland, in Switzerland, and in other countries of Europe. The shops have been usually supplied from the Levant with dried roots, which do not appear to be superior to those of our own growth. The root of this plant has a very agreeable flavour, which is greatly improved by drying. It is reckoned carminative and stomachic, having a warm, pungent, bitterish taste, so is frequently used as an ingredient in bitters.

Acorus, a blue coral, found on the coasts of Africa, from Rio del Re, to the river Camarones. It grows in form of a tree, on a rocky bottom.

ACOUSMATICI, in Grecian antiquity, such disciples of Pythagoras as had not finished their five years probation.

ACOUSTICS, the science of hearing, or of sounds in general. See Pneumatics.

Acoustic *duct*, in anatomy, a name sometimes given to the external passage of the ear, more usually called meatus auditorius. See Anatomy.

Acoustic *instrument*, or ear trumpet, one contrived to assist hearing. It is fashioned in manner of a horn, with a perforation in the smaller end, which is fitted to be put into the ear.

ACQUEST, or Acquits, in law, denotes goods not descended by inheritance, but acquired by purchase or donation.

ACQUIETANDIS *plegiis*, in law, a writ which lies for a surety against a creditor, who refuses to acquit one after the debt is paid. *Cowell.*

ACQUIETANTIA *de shires et hundredis*, a freedom from suits and services in shires and hundreds.

ACQUITTAL, in law, is a deliverance or setting free from the suspicion of guilt.

Acquittal is either in fact, or in law; in fact, it is where a person, on a verdict of a jury, is found not guilty: in law, it is when two persons are indicted, one as a principal, &c. the other as accessory: here if the former is discharged, the latter of consequence becomes acquitted.

It is also used for a freedom from entries and molestations of a superior lord, on account of services issuing out of land.

ACQUITTANCE, a discharge in writing for a sum of money, witnessing that the party has paid the same.

Every man is obliged to give an acquittance on receiving money; and a servant's acquittance for money received for the use of his master, shall bind him, provided the servant used to receive his master's rents. An acquittance is a full discharge, and bars all actions, &c.

ACRE, a measure of land containing four square roods, or one hundred and sixty square poles.

The *arpent*, or French acre, is equal to $1\frac{1}{4}$ of the English acre. That of Strasburg is only about one half of the English acre. The Scotch acre is to the English acre by statute, as 100,000 to 78,694.

We have computations of the number of acres contained in several countries; thus, England is said to contain forty-six millions and upward; and the United Provinces about four and one third millions.

Acre *tax*, a tax levied upon lands, at a certain rate by the acre, otherwise called acre shot.

ACRID, an appellation given to such matter as is of a sharp or pungent taste.

Ancient naturalists distinguished two kinds of acrid tastes; one proceeding from hot and dry, as in pepper; the other from hot and moist, as in garlic.

ACRIFOLIUM, signifies any prickly leaved plant.

ACROATIC, in the Aristotelian schools, a denomination given to such lectures as were calculated only for

the intimate friends and disciples of that philosopher; being chiefly employed in demonstrating some speculative or abstruse part of philosophy. Acroatic is also used, in a more general sense, for any thing that is sublime or abstruse; thus we read of an acroatic philosophy, theology, &c.

ACROATICI, an appellation given to such of Aristotle's disciples as were instructed in his acroatic, or sublime philosophy. The acroatic lectures stood contradistinguished from the exoteric, which were adapted to a common auditory.

ACROBATICA, or ACROBATICUM, in Grecian antiquity, an engine on which people were raised aloft, that they might have the better prospect.

ACROCHIRISMUS, in Grecian antiquity, a kind of gymnastic exercise performed with the fists, without closing at all.

ACROCHIRISTES, in Grecian antiquity, one who practised, or excelled at, the exercise called acrochirismus.

ACROCHORDUS, or Warted Snake, a genus of snake, with body and tail completely covered with warts: there are three species; 1st, the Acrochordus Javanicus, which is whitish beneath, with the sides marked by dusky spots. The remarkable snake which gave rise to the institution of this new genus, is a native of the island of Java, and was first described by Mr. Hornsted in the Swedish transactions for the year 1787. It was found in a large pepper ground near Sangasan, in the year 1784, and measured about eight feet in length; the thickness of the neck being six inches, that of the largest part of the body ten inches, and that of the tail an inch and an half: the colour of the upper part of the animal was blackish, and of the under part whitish; the sides marked with dusky spots: the head truncated, depressed, and scaly: the jaws equal, the superior being emarginated beneath; the inferior curved: the eyes lateral, on the fore part of the head; the irides lived: the nostrils circular, small, approximated, and situated above the tip of the snout: the rictus or gape rather small for the size of the body: the teeth in both jaws subulate, very sharp, and reversed, without any appearance of fangs, and accompanied by a double row of very small teeth in the palate: the tongue thick at the base, the forked part black and slender: the body entirely covered, as well as the tail, with rough tricarinated warts: the vent small, the body very suddenly tapering toward the tail. This snake was secured by a Chinese, by means of a split bamboo applied over its neck, and thus carried to Batavia, where, on being skinned and opened, exclusive of a quantity of indigested fruit, were found five completely formed young, measuring nine inches each; the flesh of the animal was eaten by the Chinese people, who affirmed that it was excellent food, and the skin, being preserved in spirits, was brought over to Europe by Mr. Hornsted, and deposited in the museum of the king of Sweden.

2dly, Doubtful or Brown Acrochordus, with carinated abdomen, and sides spotted with black. In its general appearance and proportion so very nearly does the present serpent resemble the preceding, or Javan species, that one description might almost serve for both, except that the head in this is covered with very minute rough or warted scales, differing in size alone from those on other parts of the animal; whereas, if we may rely on the accuracy of Mr. Hornsted's description and figure of the Javan Acrochordus, that part is covered with flat, ovate scales, and of a far different appearance from the muricated or wartlike scales on every other part. The size of the present specimen also falls much short of the former, measuring only about three feet in length: its colour is an obscure brown, with some ill defined clouds and patches of a darker colour dispersed along the sides and abdomen; the shape of the vent, thickness of body, and sudden contraction at the beginning of the tail, as well as the comparative size and shape of that part are exactly similar: the abdomen, however, in this serpent is slightly carinated beneath toward the tail, which is a circumstance not particularized in Mr. Hornsted's description of the Javan species. The present specimen is in the British Museum, and the engraving which accompanies this article will show in the most satisfactory manner the resemblances and discrepances between this and the former animal. Its native place is not particularized. See Plate Nat. Hist. fig. 7.

3dly, Fasciated Acrochordus, with carinated abdomen, and whitish ascendent lateral bands. This is so much allied to the preceding, that it may perhaps be doubted whether it really differs in any other respect than age, size, and cast of colours, measuring about 18 inches in length, and being of a dusky brown colour, with several paler fasciæ which take their rise from the abdomen, and ascend on the sides; the abdomen is carinated, as in the former. This is certainly the Hydrus granulatus of Mr. Schneider, who, in his work on the Amphibia, describes it as a water snake, though, seemingly, without any other foundation than its having a carinated abdomen; its other characters by no means agreeing with those of the genuine Hydri.

ACROMION, or ACROMIUM, in anatomy, the name of the upper part of the scapula, or shoulder blade. See ANATOMY.

ACROMONOGRAMMATICUM, a kind of poem, wherein every verse begins with the same letter with which the preceding verse terminates.

ACROSPIRED, in malt making, a term used for such grains of barley as shoot or sprout out at the blade end, as well as at the root end.

ACROSTIC, in poetry, a kind of poetical composition disposed in such a manner, that the initial letters of the verse make some person's name, title, motto, &c.

ACROSTICUM, *Wall Rue*, the name given by Linnæus to a distinct genus of fern, of the class and order crytogamia filices, formerly called ruta. The generic character is, that the fructification covers the whole under the surface of the frond. The species are 44 in number, two only of which are natives of Britain.

ACROSTOLIUM, in the naval architecture of the ancients, the extreme part of the ornament used on the prows of their ships. This was of various forms; sometimes in the shape of a buckler, helmet, animal, &c. but more frequently circular, or spiral. It was usual to tear the acrostolia from the prows of vanquished ships, as a token of victory. Authors, not unfrequently, confound the acrostolia with the decorations of the poop, as also with the rostra; from which, however, they are very distinct.

ACROTELEUTIC, among ecclesiastical writers, an appellation given to any thing added at the end of a psalm or hymn; as the *gloria Patri*, or doxology.

ACROTERIA, in architecture, small pedestals upon which globes, vases, or statues, stand at the ends or middle of pediments, or frontispieces. The height of those at the extremes should be only half that of the tympanum; whereas that in the middle ought to be one eighth part more.

Acroteria likewise denotes the figures placed as ornaments, or crownings, on the tops of churches; and sometimes sharp pinnacles standing in ranges about flat buildings, with rails and balusters.

Acroteria, among ancient physicians, a term used to denote the larger extremities of the body, as the head, hands, and feet.

Acroteria is also used for the tips of the fingers, and sometimes for the eminences of the bones.

ACT, among logicians, denotes an operation of the human mind; in which sense comprehending, judging, willing, &c. are called acts.

Act, among lawyers, is used for an instrument or deed in writing, serving to prove the truth of some bargain or transaction. Thus, records, certificates, &c. are called acts.

Act is also used for the final resolution, or decree, of an assembly, senate, council, &c.

Acts of parliament are called statutes; acts of the royal society, transactions; those of the French academy of sciences, memoirs; those of the academy of sciences at Petersburg, commentaries; those of Leipsic, *acta eruditorum;* the decrees of the lords of session at Edinburgh, *acta sederunt*, &c.

Act, in the universities, a thesis maintained in public by a candidate for a degree. At Oxford, the term when masters or doctors complete their degrees, is called *the act*, which is held with great solemnity: at Cambridge, it is called the *commencement*, as being the commencement of the long vacation.

Act *of faith, auto da fé*, in the church of Rome, a kind of jail delivery, for burning or setting at liberty the prisoners of the inquisition, or heretics, as they are called.

An act of faith is the utmost exertion of brutal tyranny, and a reproach to humanity itself; the tragical part of which is thus described by those who have seen it. The prisoners being clothed in peculiar habits, are carried in solemn procession to the place of execution; where there are as many stakes set up as there are prisoners to be burnt, with a quantity of dry furze about them. Those who make profession of dying in the communion of the church of Rome, are first strangled, and then burnt to ashes; but those who persist in their heresy, are chained to stakes about four feet high, a board being fixed on the top of the stake, on which the victim is seated. This being done, the jesuits, after repeated exhortations to be reconciled to the church, deliver them over to the devil, who they tell them is standing at their elbow to receive their souls, and carry them with him into the flames of hell; which instance of popish charity is followed by loud shouts from the deluded mob, exclaiming *let the dogs' beards be singed;* this they do by holding a bush of flaming furze, fastened to a pole, to their faces, till they are burnt to a coal. At last, fire is set to the furze at the foot of the stake; but the unhappy sufferers are placed so high, that the flame seldom reaches above the seat on which they sit, so that they seem rather roasted than burnt.

Such is the wretched death these poor victims suffer, and that for no other reason (for crime it certainly is not) than that they do not believe all the absurdities of popery! There cannot be a more lamentable spectacle; yet it is beheld by both sexes, and by persons of all ages, with transports of joy and satisfaction. How shocking is the practice! how detestable, beyond expression, are the authors and promoters of it! From such a religion, and such diabolical maxims, will not every protestant most fervently pray God to deliver us?

As to those who escape the flames, some are imprisoned, and others obliged to do penance during their lives.

ACTA denoted, among the Romans, a pleasant garden formed near the bank of a river, in which they gave themselves up to all kinds of pleasure.

ACTÆA, or herb Christopher, a genus of the polyandria monogynia class and order. The essential character is, calyx four leaved; corolla four petalled; berry one celled; seeds semiorbicular, in two rows.

The genus includes four known species; one of which, the actæa spicata, grows wild in England, and is sometimes used in medicine as a powerful repellent. Caution, however, is necessary in employing it. The actæa racemosa is an American plant, and is called black snakeroot, to distinguish it from the common snakeroot. It is used in that country as an antidote against several kinds of animal poisons, and particularly that of the rattlesnake.

ACTS, in dramatic poetry, are certain divisions, or parts of a play, designed to give some respite both to the actors and spectators. The acts are always five in regular and finished pieces: a rule not unknown to the Romans, as appears from Horace.

Neu brevior quinto, neu sit productior, actu.

According to some critics, the first act, besides introducing upon the stage the principal characters of the play, ought to propose the argument or subject of it; the second, to bring this into action; the third, to raise obstacles and difficulties; the fourth, to find remedies for these, or to raise new ones in the attempt; the fifth concludes the piece by introducing some incident to unravel the whole plot.

ACTIAN *games*, in Roman antiquity, those instituted in commemoration of the victory at Actium. Strabo, whose opinion is now generally followed, tells us, that they returned only every fifth year, and were sacred to Apollo, thence called *actius*.

Actian *years*, an era, or series of years, commencing from the battle of Actium, and otherwise called the era of Augustus.

ACTINIA, a genus of the mollusca order of worms; its body is rough and wrinkled, furnished with eccentric cirri and with a single terminal aperture; it attaches itself to rocks and other substances, among which it is found. These animals are called urtica marina, sea anemonies and nettles; the latter appellation is given from the painful sensation experienced when they are handled. They are viviparous, and feed on shell fish. There are five species.

ACTION, in mechanics and physics, is the pressure or percussion of one body against another. It is one of the laws of nature, that action and re-action are equal; that is, the resistance of the body moved is always equal

to the force communicated to it; or, which is the same thing, the moving body loses as much of its force as it communicates to the body moved. See MECHANICS.

ACTION, in rhetoric, may be defined, the accommodation of the voice, but more especially the gesture of an orator, to the subject he is upon. It is chiefly directed to the passions of the audience.

The power of action has been known at all times. Cicero tells us, "That it does not so much matter what an orator says, as how he says it." Horace, in his Art of Poetry, is no less explicit in setting forth its vast influence on mankind.

> With those who laugh, our social joy appears;
> With those who mourn, we sympathize in tears.
> If you would have me weep, begin the strain;
> Then I shall feel your sorrows, feel your pain.

After all, the utility, and even morality, of studied action is controverted. It is certainly enough if an orator studies sufficient of external grace that there shall be nothing disgusting in his manner or delivery. In truth, the attempts at theatrical action in some young orators, and particularly in the pulpit, are calculated to make themselves, and what they say, ridiculous, rather than respected, in the eyes of all judicious persons.

ACTION, in poetry, denotes much the same with the fable or subject of an epic or dramatic poem; only that the former may be real, whereas the latter is always feigned.

It is necessary to the perfection of an action that it be but one, that it be entire, that it be important or affecting, and that it have a suitable duration without being interrupted. It is no breach, however, of the unity or integrity of the principal action, that there are subordinate ones, serving to obstruct the hero's measures.

ACTION, in a theatrical sense, is nearly the same with action among orators; only the actor adapts his action to an assumed character, whereas the orator is supposed to be in reality what his action expresses, whether joyful, grieved, &c. The perfection of theatrical action consists in imitating nature, or expressing, in a lively manner, the behaviour of a man of the assumed character and circumstances.

ACTION, in painting and sculpture, denotes the posture of a statue or picture, serving to express some passion, &c.

ACTION *of the mouth*, in the manege, signifies a horse's champing upon the bit of the bridle, thereby emitting a ropy foam; which is looked upon as a sign of health, vigour, and mettle.

ACTION, in law, denotes either the demanding, in a legal manner, what is any man's due; or the process brought for recovering the same. The suit, till judgment, is properly called the action; but not after; and therefore a release from all actions is no bar to execution. *Co. Litt.* 281.

Actions are either criminal or civil.

Criminal actions are to have judgment of death, as appeals of death, robbery, &c. or only judgment for damage to the injured party, fine to the king, and imprisonment. Under the head of criminal actions may likewise be ranked penal actions, which lie for some penalty or punishment on the party sued, whether corporal or pecuniary.

Actions upon the statute are also brought on breach of any statute, or act of parliament, by which an action is given that did not lie before; as where a person commits perjury to the prejudice of another, the injured party shall have an action upon the statute. And, lastly, popular actions, so called, because any person may bring them on behalf of himself and the crown, by information, &c. for the breach of some penal statute. These are called *qui tam* actions, from the words of the writ.

Civil actions are divided into real, personal, and mixed.

ACTION, *real*, concerns only real or landed property, for that is the only property which our ancestors accounted real. It is therefore that whereby a man claims a title, lands, tenements, &c. in fee, or for life; and this action is either possessory, or ancestral; possessory, when the lands are a person's own possession or seisin; ancestral, when they were of the possession or seisin of his ancestors.

ACTION, *personal*, is one brought upon any contract for money or goods, or on account of trespass, or other offence committed; and thereby the debt, goods, chattels, &c. claimed.

ACTION, *mixed*, is one lying as well for the real property demanded as against the person who has it, and on which the thing is recovered with damages for the wrong sustained: such is an action of waste, sued against a tenant for life, the place wasted being recoverable, with treble damages for the wrong done.

All actions seem to be temporary and limited. A real action may be prescribed against, in five years after a fine levied, or recovery suffered. Writs of formedon for any title to lands in being, must be sued out within twenty years. Actions of debt, account, detinue, trover, and trespass, are to be brought within six years, of assault and battery within four years, and of slander within two years, after cause of action, and not afterward.

It ought, however, to be observed, that the right of action in these cases is saved to infants, feme coverts, and persons in prison, or beyond sea, &c. provided they commence their suits within the time limited after their inabilities are removed.

Actions may be brought by all persons whatever, but those attainted of high treason or felony. An outlawed or excommunicated person, &c. cannot bring any action till pardoned, absolved, &c. A feme covert must sue with her husband, and infants by their guardians.

ACTION *upon the case*, is a general action which lies for the redress of wrongs and injuries done without force, and which by law are not specifically provided against. This at present is the most frequent of all actions, being brought in all cases where no certain form has been established; and the reason why it is called an action upon the case, is because the whole cause or case is set forth in the writ. It may be brought as well where there is another action as where no other lies.

ACTION *upon the case for words*, is brought where a person is injured in his reputation; and for words which affect the life, office, trade, &c. or tend to the loss of preferment in marriage, or otherwise; or to the disinheritance, or other damage of a person.

ACTION *prejudicial*, otherwise called *preparatory*, one which arises from some doubt in the principal; as, where one sues his younger brother for lands descended from the father, on which it is objected to him that he is a bastard. Here this point of bastardy is to be first tried or judged, before the principal cause can proceed.

ACTION *of a writ*, is when a person pleads some matter, by which is shown, that the plaintiff had no cause to have the writ brought; though, perhaps, he may have another writ for the same matter. It is hence called, a plea to the action of the writ, in contradistinction from a plea to the action.

ACTION, among physicians. The actions of the human body are divided into the vital, animal, or natural ones.

Vital actions are those, without which life could not be maintained: such is the motion of the heart and lungs.

Under animal actions are comprehended the senses, imagination, judgment, and voluntary motions, without which we could not live comfortably.

Lastly, natural actions are those which, though not so immediately necessary to life, but that we may live some time at least without them, yet are absolutely necessary to our well being: such is digestion.

ACTION, in commerce, a term used abroad for a certain part or share of a public company's capital stock. Thus, if a company has 400,000 livres capital stock, this may be divided into 400 actions, each consisting of 1,000 livres. Hence, a man is said to have two, four, &c. actions, according as he has the property of two, four, &c. thousand livres, capital stock.

The transferring of actions, abroad, is performed much in the same manner as stocks are with us.

ACTIONARY, or ACTIONIST, in commerce, a term used among foreigners, for the proprietor of an action, or share of a public company's stock.

ACTIVE, among grammarians, an appellation given to words expressing some action, as I write, I read, &c.

These are denominated verbs, or active verbs, from the Latin *verbum*, a word.

ACTOR, in a theatrical sense, is a man who acts some part or character in a play.

Actors were at first few in number, one or two persons often acting all the characters in a play. At present, however, their number is not limited: a circumstance which creates such a diversity as must greatly interest the spectators.

It is remarkable with what difference actors were treated among the ancients. At Athens they were held in such esteem, as to be sometimes appointed to discharge embassies, and other negotiations: whereas, at Rome, if a citizen became an actor, he forfeited his freedom. Among the moderns, actors are best treated in England; the French having much the same opinion of them as the Romans had.

ACTOR was the name of a person who had the superintendence of all the goods of a Roman citizen. He was called *actor bonorum*.

ACTOR *summarum*, a slave, to whom was committed the office of cash keeper.

ACTOR, among civilians, the proctor or advocate in civil courts or causes.

ACTORUM *tabulæ*, tables instituted by Servius Tullius, in which the births of children were registered.

ACTUARIÆ *naves*, in Roman antiquity, a kind of ships designed chiefly for expedition.

ACTUARIUS, an officer, or rather notary, appointed to write down the proceedings of a court.

ACTUARII were also officers who kept the military accounts, and distributed the corn to the soldiers.

ACTUS, in antiquity, a measure of length, containing one hundred and twenty Roman feet.

The square of the actus, was just half of the Roman acre or jugerum.

ACULEATE, or ACULEATED, an appellation given to any thing that has aculei, or prickles: thus fishes are divided into those with aculeated, and not aculeated fins.

ACULER, in the manege, is said of a horse, when working upon volts, he does not go far enough forward, at every time or motion; so that his shoulders embrace or take in too little ground, and his croupe comes too near the centre of the volt.

ACUMINA, in antiquity, a kind of military omen, taken from the points or edges of spears, swords, &c.

ACUPUNCTURE, in the Chinese and Japanese surgery, a method of curing several disorders, by pricking the part affected with a needle.

This operation is performed with a gold or silver needle, which they strike into the body with their hand, or with a hammer provided for that purpose. Not only the legs, arms, and the like parts, are pricked in this manner, but likewise the head and abdomen.

They have recourse to acupuncture in the head for headaches, lethargies, epilepsies, convulsions, diseases of the eyes, &c. and in the abdomen for colics, dysenteries, want of appetite, surfeits, &c.

ACUTE, an appellation given to such things as terminate in a sharp point or edge: thus, we say, an acute angle, acute angled triangle, &c. See GEOMETRY.

ACUTE *diseases*, among physicians, those which suddenly rise to their crisis, and terminate in a few days. They are extremely dangerous, as not affording time to administer proper medicines.

ACUTE, in music, an epithet given to sharp or shrill sounds, in opposition to those called grave.

ACUTIATORES, in antiquity, a kind of smiths retained in the ancient armies for sharpening the arms.

ACUTITION, in grammar, the pronouncing, or marking, a syllable with an acute accent.

AD, a Latin preposition, expressing the relation of one thing to another.

It is frequently prefixed to other words: thus,

AD *bestias*, in antiquity, a kind of punishment, which consisted in throwing the criminal to wild beasts.

AD *hominem*, among logicians, an argument drawn from the professed belief or principles of those with whom we argue.

AD *libitum*, at discretion, in music, the same with piace, or si piace.

AD *ludos*, in Roman antiquity, a kind of punishment, whereby the criminals entertained the people, either by fighting with wild beasts, or with each other.

AD *metalla*, in Roman antiquity, the punishment of such criminals as were condemned to the mines, and therefore called metallici. A piece of excellent policy, thus to make the punishment of rogues doubly subservient to the good of the commonwealth.

AD *valorem*, among the officers of the king's revenue, a term used for such duties, or customs, as are paid according to the value of the goods sworn to by the owner.

ADACTED, in military affairs, is a term applied to stakes, or piles, driven into the earth by large malls shod with iron, as in securing ramparts or pontoons.

ADAGIO, softly, leisurely, in music, a term used to denote the slowest of all times, the grave only excepted.

Sometimes it is repeated, adagio adagio, to signify a still greater retardation of time.

ADALIDES, in Spain, officers of justice for matters that respect the military forces.

ADAMANTINE *spar*. See MINERALOGY.

ADAMANTINE, *terræ*, the sixth order of earths; to this order belongs the *corundum*.

ADAMI *pomum*, in anatomy, a prominence in the fore part of the throat; so called from an idle notion, that a piece of the forbidden apple stuck in Adam's throat, and occasioned this tumour, which in reality is only the convex part of the first cartilage of the larynx.

ADAMIC, *earth*, *terra adamica*, a name by which some call the common red clay supposed to be the adamah, or ruddy earth, of which the first man was formed.

ADAMITES, a sect of heretics who went naked; pretending that mankind were restored to the original state of innocence, wherein Adam was created.

ADANSONIA, Ethiopian sour gourd, or monkey's head, is a genus of the monadelphia order and polyandria class, called after the famous French traveller in Senegal, Adanson. The essential character is, calyx simple, deciduous; style very long; stigmas many; capsules woody, ten celled, with farinaceous pulp, and many seeds.

We know of but one species, the adansonia digitata. In its native country, Africa, it grows to a very large tree. Its height however is not above twelve or fifteen feet, but its circumference is often sixty or seventy feet. The fruit is pleasant, of an acid flavour, and eaten with sugar. The pulp, or a syrup made of it, is used in putrid fevers; and at Cairo the pulp reduced to a powder is administered in fluxes, dysenteries, &c. It has grown, from seeds sown in a hotbed, to the height of eighteen feet in our stoves.

ADAR, in Hebrew chronology, the twelfth month of the ecclesiastical, and the sixth of the civil year. It has only twenty-nine days, and answers to the last half of our February and the first part of March.

ADARCON, a coin mentioned in the Scriptures, usually of gold, worth about fifteen shillings.

ADARME, in commerce, a small Spanish weight used in America, and nearly equivalent to our dram.

ADCRESCENTES *milites*, under the Roman emperors, a kind of junior soldiers, not unlike our cadets.

ADDER. See COLUBER.

ADDEXTRATORES, the pope's mitre bearers; so called, according to Ducange, on account of their walking at the pope's right hand, when he rides to visit the churches.

ADDICTI, in Roman antiquity, slaves who were reduced to that state because they could not satisfy some creditor; whose slaves they became till they could pay or work out the debt.

ADDICTION, *addictio*, among the Romans, was the making over of goods to another, whether in the way of sale, or by sentence of court: the goods so delivered were called *bona addicta*.

Debtors were sometimes delivered over in the same manner, and thence called *servi addicti*, as above.

ADDITION, in arithmetic, the first of the four fundamental rules of that art: for this, and addition of fractions and decimals, see ARITHMETIC.

ADDITION, in algebra, is the connecting or putting together all the letters or numbers to be added, with their proper signs + or —. See ALGEBRA.

ADDITIONS, in law, denote all manner of designations given to a man, over and above his proper name and surname, to show what estate, degree, mystery, place of abode, &c. he is.

ADDITIONS of degree, are the same with titles of honour, or dignity; as knight, lord, earl, duke, &c.

ADDITIONS of estate, are yeoman, gentleman, esquire, &c.

ADDITIONS of mystery or trade, are carpenter, mason, painter, engraver, &c.

ADDITIONS of place or residence, are London, Edinburgh, Bristol, York, Glasgow, Aberdeen, &c.

These additions were ordained to prevent one man's being grieved, or molested, for another; and that every person might be certainly known, so as to bear his own burden.

If a man is of different degrees, as duke, earl, &c. he shall have the most worthy; and the title of knight, or baronet, is part of the party's name, and therefore ought to be rightly used; whereas that of esquire, or gentleman, being as people please to call them, may be used or not, or varied at pleasure.

An earl of Ireland is no addition of honour here; nay, the law addition to the children of British noblemen is only that of esquire, commonly called lord.

Writs without the proper additions, if excepted to, shall abate; only where the process of outlawry does not lie, additions are not necessary. The addition of a parish not in any city, must mention the county, otherwise it is not good.

ADDITION *of ratios*, the same with what is otherwise called composition of ratios.

ADDITION, among distillers, a general term for such things as are added to the wash, or liquid, while fermenting, with a view to increase the vinosity and quantity of the spirit, or to give it a particular flavour.

ADDITION, in heraldry, something added to a coat of arms, as a mark of honour; and therefore directly opposite to abatement. Among additions we reckon a border, quarter, canton, gyron, pile, &c. In this manner the arms of a kingdom or state have been added to those of noblemen; as happened to the dukes of Boufflers and Richlieu in the Italian war, who, by a decree of the senate of Genoa, were permitted to add the ensigns of that republic to those of their families.

ADDITION, in music, a dot marked on the right side of a note, to signify that it is to be sounded or lengthened half as much more as it would have been without such mark.

ADDUCTOR, in anatomy, a general name for all such muscles as serve to draw one part of the body toward another. See ANATOMY.

ADEB, in commerce, a weight used in Egypt, principally for weighing rice. It is about two drams less than an English pound.

ADELIA, a genus of the diocecia monadelphia class and order. Its essential character is, male blossom; calix three parted; corolla none; stamina many, united at the base. Female, calix five parted; corolla none, styles three torn, caps. tricoccous.

There are three species of shrubs which bear this name, all of them natives of Jamaica. We do not find them remarkable for any particular quality, and therefore, as their flower has no beauty, they are seldom cultivated here. They may, however, be raised from seed, and treated as stove plants.

ADELPHIANI, a sect of heretics, who always fasted on Sundays.

ADEMPTION, among civilians, denotes the revocation of some donation or favour.

The ademption of a legacy may be done either in express terms, or indirectly by disposing of it otherwise.

ADENANTHERA, a genus of shrubby plants of the class and order decandria monogynia. The flower is companulate; and the essential character is, calyx five toothed, petals five, globose glands affixed to the outer tip of the anthers, whence its name, legume membranaceous.

Three species are at present known, but the adenanthera pavonina is the only one which has been as yet cultivated in England, where, however, it has not flowered. The seeds, which are obovate, rounded, and convexly lens shaped, are very beautiful, and from their equality in weight, being each four grains, are used by goldsmiths and jewellers; they are also eaten by the common people in India, and form a cement when beaten up with water and borax. It is one of the largest and handsomest trees in the East Indies, and commonly lives 200 years. The wood is solid and durable. With us it forms a handsome shrub for the decoration of our stoves.

ADENOS, a kind of cotton, otherwise called marine cotton. It comes from Aleppo by way of Marseilles, where it pays twenty per cent. duty.

ADENOSE, *abscess*, is used for a hard tubercle, difficult to be discussed, and resembling a gland.

ADESSENARIANS, a sect of Christians, who maintain that Jesus Christ is really present in the eucharist, though not by way of transubstantiation.

The adessenarians differ among themselves, some of them holding that the body of Jesus Christ is in the bread; others, that it is about the bread; others, that it is with the bread; and others, that it is under the bread.

ADFECTED *equations*, in algebra, those wherein the unknown quantity is found in two or more different powers: such is $x^3 - ax^2 + bx = a^2b$.

For the solution of these and other equations, see ALGEBRA.

ADFILIATION, a Gothic custom, whereby the children of a former marriage are put upon the same footing with those of the second marriage. This is otherwise called *unio prolium*, and still retained in Germany, under the name *einkindschafft*.

ADHESION, in physiology, is used to denote the sticking together of two bodies. Muschenbroek has given many curious experiments on the adhesion of bodies, which he properly attributes to attraction.

ADHESION, in medicine and anatomy. There are frequent instances of the adhesion of the lungs to the pleura and diaphragm, which occasions many disorders.

ADHIL, in astronomy, a star of the sixth magnitude, upon the garment of Andromeda, under the last star in her foot.

ADIANTUM, *maidenhair*, in botany, a genus of plants of the cryptogamia class, and of the order of filices. The generic character is, the fructifications collected in oval spots under the reflected tops of the fronds.

There are thirty-nine species, but only one, the adiantum capillus Veneris, is a native of Great Britain, and even that is found only in a few places in Scotland and Wales. Like the other plants of this class it has no visible flower; the seeds being contained in capsules, placed in the sinuses and folds of the leaves, and surrounded each with an elastic ring, which contracting, bursts the capsule and scatters the minute seeds: as, however, the leaves of all the species of maidenhair have one general appearance, it is easy to distinguish them from other plants of the fern kind.

Maidenhair was once highly esteemed as an expectorant, but is now generally rejected. Indeed, it has been well remarked, that if the syrop of capillaire, which is pretended to be made from it, has any virtue, it is derived from the orange flower water, which is also an ingredient.

ADIAPHORISTS, or ADIAPHORITES, names given to the modern Lutherans, in the sixteenth century. The name imports lukewarmness, or indifference; being compounded of the privative α, and $\delta\iota\alpha\phi o\rho o\varsigma$, different.

ADIAPHOROUS, an epithet given by Mr. Boyle to a spirit distilled from tartar and some other vegetable bodies: it is said to be neither acid nor urinous, and in many respects different from any other spirit.

ADJECTIVE, a word expressing some quality, or other accident, of the substantive with which it is joined: thus, in the phrase, pure gold, the word *pure* is an adjective, showing the quality of the gold. When the quality is the subject whereof we speak, it becomes a substantive: thus if we say, good is always to be chosen, the word good is a substantive; but in the phrase, Peter is a good man, the word good is evidently an adjective, expressing the character of Peter.

AD INQUIRENDUM, in law, a writ commanding inquiry to be made concerning something connected with a cause depending in the king's courts; as of bastardy, or the like.

ADJOURNMENT, in law, the putting off a court, or meeting, to another time or place.

ADJOURNMENTS *of parliament* differ from prorogations, in being not only for a shorter time, but also each house has the privilege of adjourning itself, whereas a prorogation can only be the act of the king.

ADIPOCIRE, is a term that denotes a body converted from a muscular to a waxy substance. See CHYMISTRY.

ADIPOSE, in a general sense, denotes something belonging to the fat of the body; and is a term chiefly used by physicians and anatomists, in whose writings we read of adipose cells, adipose ducts, adipose membrane, adipose vessels, &c.

ADJUDICATION, is sometimes used for transferring the property of a thing sold by auction to the highest bidder.

ADJUNCT, among philosophers, something added to another, to which it does not naturally belong: thus water in a sponge is an adjunct to it; so are clothes to a man. Adjuncts are what we commonly call circumstances; these, in ethics, are commonly reckoned seven, *quis, quid, ubi, quibus, auxiliis, cur, quomodo, quando.*

ADJUNCTS, in the Paris academy of sciences, are a set of members attached to the study of some particular

science. They are twelve in number; two for geometry, two for astronomy, two for anatomy, two for mechanics, two for chymistry, and two for botany.

AD JURA REGIS, in law, a writ which lies for a clerk presented to a living by the king, against those who endeavour to eject him, to the prejudice of the king's title.

ADJUTAGE, or AJUTAGE, in hydraulics, the tube fitted to the mouth of a jet d'eau.

It is through the adjutage that water is played and directed into any desired figure; so that the great diversity of fountains consists chiefly in the different structure of their adjutages.

ADJUTANT, in the military art, an officer whose business it is to assist the major, and therefore sometimes called the aid major.

Each battalion of foot, and regiment of horse, has an adjutant, who receives the orders every night from the brigade major, and after carrying them to the colonel, delivers them out to the serjeants. When detachments are to be made, he gives the number to be furnished by each company, and assigns the hour and place of rendezvous; he also places the guards; receives and distributes the ammunition to the companies; and by the major's orders regulates the price of bread, beer, &c.

ADJUTANTS *general*, among the Jesuits, were a select number of fathers who resided with the general of that order; they had each a province or country assigned them, as England, Germany, &c. and their business was to inform the father general of state occurrences in such countries.

ADLEGATION, in the customs of Germany, a right claimed by several princes of that empire to send plenipotentiaries, conjunctly with those of the emperor, to all negotiations wherein the empire in general is concerned.

The emperor disputes this privilege of adlegation, but allows them to send ambassadors about their own private affairs.

ADMANUENSES, in our old law books, a term denoting laymen, who swore by laying their hands on the book; whereas the clergy were forbidden to swear on the book, their word being deemed equal to an oath.

ADMEASUREMENT, in law, a writ for adjusting the shares of something to be divided. Thus,

ADMEASUREMENT *of dower* takes place when the widow of the deceased claims more as her dower than what of right belongs to her. And,

ADMEASUREMENT *of pasture* may be obtained when any one of the persons who have right in a common pasture, puts more cattle to feed on it than he ought.

ADMINICULATOR, in church history, an officer otherwise called advocate of the poor.

ADMINISTRATION, in law, the office of an administrator. See ADMINISTRATOR.

Whenever a man dies intestate, letters of administration are taken out in the prerogative court.

ADMINISTRATION is also used for the management of the affairs of a minor, lunatic, &c.

ADMINISTRATION, among ecclesiastical writers, denotes the power wherewith a parson is invested; and that as well in regard to the temporalities of his cure, as to its spiritualities, *viz.* the power of excommunicating, of administering the sacraments, &c.

ADMINISTRATION, among anatomists, denotes the art of properly dissecting the parts of the human body, and particularly of the muscles.

ADMINISTRATION, in commerce, a regulation at Calao, a city of Peru, obliging all ships allowed to trade on the coast, to unload their European goods, and pay certain duties.

ADMINISTRATOR, in law, the person to whom the goods, effects, or estate, of one who died intestate, are intrusted; for which he is to be accountable, when required.

The bishop of the diocese where the party dies, is regularly to grant administration; but if the intestate has goods in several dioceses, administration must be granted by the archbishop in the prerogative court.

The persons to whom administration is granted, are a husband, wife, children whether sons or daughters, the father or mother, brothers or sisters, and, in general, to the next of kin, as uncle, aunt, cousin; then to a creditor.

An action lies for and against an administrator, as for and against an executor; he is accountable, however, no further, than to the value of the goods.

ADMINISTRATOR is also used in several other senses, as for an advocate of a church; for a person appointed to receive and manage the revenues of an hospital or religious house; for a prince who enjoys the revenues of a secularized bishopric; and lastly, for the regent of a state during a minority, or a vacancy of the throne.

ADMIRAL, in maritime affairs, a great officer, who commands the naval forces of a kingdom or state, and decides all maritime causes.

According to Ducange, the Sicilians were the first, and the Genoese the next, who gave the name of admiral to the commanders of their fleets; deriving it from the Arabic *amir* or *emir*, a designation applicable to any commanding officer.

For some time past, we have had no lord high admiral in Britain; that office being executed by a certain number of commissioners, called lords of the admiralty.

ADMIRAL also denotes the commander in chief of a single fleet or squadron; or, in general, any flag officer whatever.

In the British navy, besides the admiral who commands in chief, there are the vice admiral, who commands the second squadron; and the rear admiral, who commands the third division. The admiral carries his flag at the main topmast head; the vice admiral at the fore topmast head; and the rear admiral at the mizen topmast head.

The admiral when on shore, is entitled to receive military honours, and ranks with generals in the army.

ADMIRAL, *Vice*, likewise denotes an officer invested with the jurisdiction of an admiral, within a certain county or district. There are upward of twenty such vice admirals in Great Britain; but an appeal lies from their sentence or determination, to the admiralty court in London.

In France the admiral is one of the great officers of the crown, general of the marine, and of all the naval forces of the kingdom. From him the captains and masters of trading vessels are obliged to take their licenses, passports, commissions, and safe conducts.

The tenth of all prizes belongs to him, and the whole of all fines adjudged in the courts of admiralty. He also has the duty of anchorage, tonnage, &c.

ADMIRAL is also an appellation given to the most considerable ship of a fleet of merchantmen, or the vessels employed in the cod fishery of Newfoundland. This last has the privilege of choosing what place he pleases on the sandy shore, to dry his fish. He also gives proper orders, and appoints the fishing places to those who come after him; and as long as the fishing season continues, he carries a flag on his mainmast.

ADMIRAL, in conchology, the name of a beautiful shell of the volute kind, much admired by the curious.

There are four species of this shell, *viz.* the grand admiral, the vice admiral, the orange admiral, and the extra admiral. The first is extremely beautiful, of an elegant white enamel, variegated with bands of yellow, which represent, in some measure, the colours of the flags in men of war. It is of a very curious shape, and finely turned about the head, the clavicle being exerted; but its distinguishing character is a denticulated line, running along the centre of the large yellow band; by this it is distinguished from the vice admiral, the head of which is also less elegantly formed.

The orange admiral has more yellow than any of the others, and the bands of the extra admiral run into one another.

ADMIRALTY, properly signifies the office of lord high admiral, whether discharged by one, or several joint commissioners called lords of the admiralty.

In Holland there are five admiralties, boards, or chambers, composed of the deputies of the nobles, the provinces, and towns; who have the care of fitting out fleets, and in general, of all maritime affairs.

ADMIRALTY *Court*, or court of admiralty, in the British polity, a sovereign court, held by the lord high admiral, or the commissioners of the admiralty.

This court has cognisance in all maritime affairs, civil as well as criminal.

All crimes committed on the high seas, or in great rivers, beneath the bridge next to the sea, are cognisable only in this court; which, by statute, is obliged to try the same by judge and jury. But in civil causes it is otherwise, these being all determined according to the civil law; the reason of which is, that the sea is without the jurisdiction of the common law.

In case any person is sued in the admiralty court, contrary to the statutes, he may have the writ of supersedeas to stop further proceedings, and also an action for double damages against the person suing.

Subordinate to this court there is another of equity called court merchant; wherein all causes between merchants are decided, agreeably to the rules of the civil law.

ADMIRATION, in a general sense, denotes the act of being much delighted with, or highly prizing, some rare excellence; and sometimes the astonishment conceived at some extraordinary event.

"It is obvious," says Dr. Cogan, "that the range of *admiration* is from the simple approbation of the mind, up to the most lively sensation, according to our conceptions of the extent of excellence, and also the degrees of our interest in its effects. It is also blended with various other emotions according to different circumstances attendant upon the passion. It is frequently introduced by *surprise!* when, for example, the discovery of these excellencies is sudden and unexpected, and then it becomes a vivid emotion. It is generally connected with some degree of *wonder;* as we are frequently ignorant of the causes which enabled any one greatly to excel ourselves or others; but as it is always excited by the real discovery of some qualities, it is not to be confounded with an emotion that proceeds from ignorance and embarrassment previous to the discovery." Grammarians have a character for expressing this affection or state of mind, called a point of admiration, and marked thus (!)

ADMISSION, among ecclesiastical writers, denotes the act of a bishop's admitting or allowing a clerk to be able, or qualified for serving a cure. This is done after examination, by pronouncing the formula *admitto te habilem.* If any person presume to be admitted, who has not episcopal ordination, he shall forfeit 100*l.* No person is to be admitted into a benefice with a cure of 30*l.* per annum in the king's books, unless he is a bachelor in divinity at least, or a preacher lawfully allowed, or licensed by some bishop.

ADMITTENDO *clerico*, a writ granted to a person who has recovered his right of presentation in the common pleas: by which the bishop or metropolitan, is ordained to admit his clerk.

ADMITTENDO *in socium*, a writ associating certain persons, usually knights, and other gentlemen of the county, to the justices of assize already appointed.

ADMONITIO *fustium*, among the Romans, a military punishment, not unlike our whipping, only that it was performed with vine branches.

ADMONITION, in church history, a part of discipline, which consists chiefly in warning an offender of the irregularities he is guilty of, and advising him to amend.

By the ancient canons, nine admonitions were required before excommunication.

ADMORTIZATION, in the feudal customs, reducing the property of lands or tenements to mortmain.

ADNATA, in anatomy, one of the tunics or coats of the eye, otherwise called conjunctiva and albuginea.

It is the same part with what is called the white of the eye, formed by the tendinous expansions of the muscles which move the eye. See ANATOMY.

ADNATA, or ADNASCENTIA, among gardeners, terms used for such offsets, as by a new germination under the earth, proceed from the lily, narcissus, hyacinth, and other flowers; and afterward grow to the roots. These by the French are called *cayeux.*

ADNATA is also a term used for such things as grow upon animal or vegetable bodies, whether inseparably, as hair, wool, horns, &c. or accidentally, as the several epistitical plants.

ADNOUN, or ADNAME, terms sometimes used to denote an adjective.

ADONIA, festivals kept in honour of Venus, and in memory of her beloved Adonis.

The adonia lasted two days, on the first of which the images of Venus and Adonis were carried with great solemnity, in manner of a funeral; the women crying all the while, tearing their hair, and beating their breasts. On the second, changing their note, they sung his praises, and made rejoicings, as if Adonis had been raised to life again.

The adonia were celebrated by most ancient nations, as the Greeks, Egyptians, Syrians, Lycians, &c. The

prophet Ezekiel, c. viii. verse 14. is thought to allude to these festivals.

ADONIC, in ancient poetry, a kind of verse consisting of a dactyle and spondee or trochee. This kind of verse had its name adonic, on account of its being originally used in the lamentations for Adonis. However, its principal use among poets, is to serve as a conclusion to each strophe of sapphic verse.

ADONICUS, a name given by the Arabs to the sun, under which appellation they worshipped him, by daily offering him incense and perfumes.

ADONIDES, an appellation given to such botanists as have given descriptions or catalogues of the plants cultivated in some particular place.

ADONIS *flos*, a genus of plants, called in English pheasant's eye. It is of the class and order polyandria polygynia; and the essential character is, calyx five leaved; petals, five or more without a nectary; seeds naked.

The genus includes six species, much resembling the anemone in appearance, only smaller. The adonis autumnalis, an annual plant, is common in our gardens, and even in the fields about London. Its flowers are of a bright scarlet, with a black spot or eye at the bottom. The adonis vernalis is also cultivated in our gardens; but though a native of Switzerland and Germany, we have observed that it is somewhat tender, probably from its shooting so early in the spring; it has a large yellow flower.

ADOPTIANI, a sect who maintained that Christ, with respect to his human nature, was not the natural, but adoptive son of God.

ADOPTION, a solemn act, whereby one man made another his heir; investing him with all the rights and privileges of a son.

Adoption was in frequent use among the Greeks and Romans, who had many regulations concerning it. The Lacedemonians, in order to prevent inconsiderate adoptions, had a law, that they should be transacted, or at least confirmed, before their kings; at Athens, slaves, madmen, and persons under age, were incapable of adopting; and at Rome, adoptions were confirmed before the prætor, in an assembly of the people, or by a rescript of the emperor. Young men were not permitted to adopt their elders; on the contrary, it was necessary that the adopter should be eighteen years older than his adopted son, to give an appearance of probability of his being the natural father. Children, thus adopted, were invested with all the privileges, and obliged to perform all the duties, of legitimate children, even to the assuming the names of the person who adopted them: and being thus provided for in another family, they ceased to have any claim for inheritance, or kindred, in the family they had left, unless they first renounced their adoption; which, by Solon's laws, they were not permitted to do, till they had begotten children to bear the name of their adopted father. On the other hand, the person who had once adopted children, was not permitted to marry afterward, without express leave from the magistrate; whom it was usual to petition for such a licence, in case the adopted children acted an ungrateful part.

Among the Romans, before adoption could take place, the natural father was obliged to renounce all authority over his son, and with great formality consent that he should be translated into the family of the adopter. The adoption of a person already free was called adrogation. The ceremonies of adoption being various, have given rise to a great many different kinds of it: thus, we read of adoption by testament, when a man adopted another by his last will; adoption by arms, or presenting the adopted son with a suit of armour; adoption by cutting off the hair; adoption by matrimony, or adopting the children of a wife by a former husband.

By the Gentoo laws, information must be given to the magistrate, by the person who is desirous of adopting a child, and a sacrifice performed, and he is also to give gold and rice to the father of the child. A woman is not allowed to adopt a child without her husband's order; and he who has no son, or grandson, or great grandson, has liberty to adopt one son, but no more. Among the Turks, the ceremony of adoption is performed by obliging the person adopted to pass through the shirt of the adopter. Hence among that people, to adopt is expressed by the phrase, "to draw another through my shirt."

ADOPTION is also used in speaking of the admission of persons into certain hospitals, particularly that of Lyons: sometimes the term is used in the sense of incorporation; thus the French academy of Marseilles was *adopted* by that of Paris.

ADOPTIVE *arms*, in heraldry, those enjoyed by the concession of another, which the adopter is obliged to marshal with his own, as being the condition of some honour or estate left him.

ADOPTIVE is sometimes also used for borrowed or foreign; thus, besides their domestic gods, the Romans had a multitude of adoptive deities, borrowed from foreign nations.

ADORATION denotes the act of worshipping God, or a being supposed to be God. The word comes from *ad*, to; and *os*, *oris*, the mouth; and imports, to kiss the hand, this being universally acknowledged to be a mark of great respect. Among the Jews, adoration consisted in kissing the hands, bowing, kneeling, and even prostration. Hence, in their language, the word kissing is used for adoration. As to the ceremony of adoration among the Romans, it was performed with the head veiled, or covered; the devotee applying his right hand to his lips, the fore finger resting on the thumb, which was erect; and then bowing, he turned himself round from left to right. The Gauls, on the contrary, thought it more religious to turn from right to left; and the Greeks, to worship with their heads uncovered. The Christians follow the Grecian rather than the Roman mode, by uncovering, when they perform any act of adoration.

ADORATION, *barbarous*, denotes that used by heathen nations. The Phenicians adored the winds, on account of the terrible effects produced by them. The same practice was adopted by the Greeks, Persians, Romans, &c. The Troglodytes adored tortoises; the Scythians, swords; the Romans, axes; and the Arabs, stones; the Indians adored vipers; the Bengalese and the Canadians, the sun. The Manta, a Peruvian people, anciently adored a huge emerald, by offering to it emeralds of a lesser size; all of which the priests kept for their own use.

ADORATION is also used, in a civil sense, for any extraordinary homage or respect paid by one man to anoth-

er. Thus the Persians adored their kings, by falling prostrate before them, striking the earth with their foreheads, and kissing the ground. This was an act of servility, which Conon, a citizen of Athens, refused to comply with, when introduced to Artaxerxes; neither would the philosopher Calisthenes perform it to Alexander the Great, as judging it impious and unlawful. The Roman emperors were adored, by bowing or kneeling at their feet, laying hold of their purple robe, and immediately withdrawing the hand, and kissing it.

ADORATION is more particularly used for the ceremony of paying homage to the pope, by kissing his feet; which not only the people, but the greatest prelates, and even princes, make no scruple of performing. Protestants have hence taken occasion, and not without reason, to charge the popes with excessive pride, and even impiety.

ADORATION is still more particularly used for a method of electing a new pope, when the cardinals, instead of proceeding in the usual way, unanimously fall down and adore one of their own number. Adoration is the last ceremony of a regular election, but here it is the election itself, or rather supersedes it.

ADORATION, *perpetual*, in the church of Rome, a kind of religious society, frequent in the popish countries; which consists of devout persons, who, by regularly relieving each other, keep constantly praying before the eucharist both day and night.

ADOREA, in Roman antiquity, a word used in different senses; sometimes for all manner of grain; sometimes for a kind of cakes made of fine flour, and offered in sacrifice; and, finally, for a dole or distribution of corn, as a reward for some service: whence, by metonymy, it is put for praise or rewards in general.

ADOSSEE, in heraldry, a term used for two rampant animals, placed back to back. It also denotes any other figures, as axes, keys, &c. placed with their heads facing different ways.

ADOXA, a genus of plants, of the class and order of octandria tetragynia. The essential character is, calyx bifid, inferior; corolla four or five cleft, superior; berry four or five celled, united with the calyx.

We know of but one species; the adoxa moschatelina, so called from its smelling like musk. It is otherwise called bastard fumitory, and grows wild in shady places, as in Hampstead and Charlton woods.

AD PONDUS OMNIUM, among physicians, denotes that the last mentioned ingredient ought to weigh as much as all the rest put together.

AD QUOD DAMNUM, in law, a writ which ought to be issued before the king grants certain liberties, as a fair, market, highway, &c. ordering the sheriff to inquire by the country what damage such a grant is likely to be attended with.

ADRIFT, in sea language, denotes the state of a vessel broken from her moorings, and driven by the wind or waves.

ADSCENDENS *caulis*, denotes, in botany, a stalk or branch inclining upward.

ADSENTIRI, a term used to express the assent of the Roman soldiers to any propositions that were made to them by their commanders, which they did by lifting up their hands with acclamation, and striking their bucklers against their knees.

ADSIDELLA, in antiquity, the table at which the flamens sat during the sacrifices.

ADSTRICTION, among physicians, is used to denote the too great rigidity and closeness of the emunctories of the body, particularly the pores of the skin; also for the styptic quality of medicines.

AD TERMINUM *qui præteriit*, in law, a writ of entry, that lies for the lessor or his heirs, if after the expiration of a term for life or years, granted by lease, the tenant or other occupier of the lands, &c. withholds the same from such lessor.

ADVANCE, in the mercantile style, denotes money paid before goods are delivered, work done, or business performed.

To pay a note of hand, or bill, by advance, is to pay the value before it becomes due; in which case it is usual to allow a discount for the time it is preadvanced.

ADVANCED *ditch*, or moat, in fortification, is that drawn round the glacis or esplanade of a place.

ADVANCED *guard*, or VANGUARD, in the art of war, denotes the first line or division of an army, ranged or marching in order of battle; or it is that part which is next the enemy, and marches first toward them.

ADVANCED *guard* is more particularly used for a small party of horse stationed before the main guard.

ADVANCER, among sportsmen, denotes one of the starts or branches of a buck's attire, between the back antler and the palm.

ADUAR, in the Arabian and Moorish customs, a kind of ambulatory village, consisting of tents; which these people remove from one place to another, as suits their convenience.

ADVENTITIOUS, among civilians, denotes all such goods as are acquired accidentally, or by the liberality of a stranger, &c.

ADVENTITIOUS *fossils*, the same with extraneous or foreign ones, found embodied in other fossils: such are shells, bones, &c. in stone.

AD VENTREM *inspiciendum*, in law, a writ by which a woman is to be searched whether she be with child by a former husband, on her withholding lands from the heir.

ADVENTURE, *bill of*, among merchants, is a writing signed by a merchant, testifying that the goods mentioned in it to be shipped on board a certain vessel, belong to another person, who is to run all hazards; the merchant only obliging himself to account to him for the produce of them, be it what it will.

ADVENTURER, in a general sense, denotes one who hazards something. By statute 13. Geo. II. c. 4. adventurers may obtain a charter for whatever settlements in America they shall take from the enemy.

ADVENTURERS, or *merchant* ADVENTURERS, a company of merchants formerly erected for the discovery of lands, trades, &c.

ADVERB, in grammar, a word joined to verbs, expressing the manner, time, &c. of an action: thus, in the phrase, *it is conducive to health to rise early*, the word *early* is an adverb; and so of others.

Adverbs are also added to nouns, and even to other adverbs, in order to modify or ascertain their meaning, whence some grammarians call them modifications: thus, in the phrase, *he prayed very devoutly*, the word *devout-*

ly qualifies the action of prayer, and the word *very* does the same in regard to devoutly.

Adverbs, though very numerous, may be reduced to certain classes; the principal of which are those of order, of place, of time, of quantity, of quality, of manner, of affirmation, doubting, comparison, interrogation, diminution, &c.

Mr. H. Tooke has shown, in his Επεα Πτεροεντα, that most of the English adverbs are either corruptions of other words, or abridgments of sentences: thus the termination *ly* is the corruption of *like*, as honestly is honest-like. *Lo* is the imperative of *look*, &c.

By others adverbs are derived from three sources: 1, from a species of interjection, denoting an impulse of the mind, as *now, then, not;* 2, from a composition of two or three words into one, as *always, altogether*, &c. and, 3, from adjectives, by adding a syllable void of signification itself, but which seems to denote that the word has changed its state into that of an adverb, as *greatly*. The last syllable, however, was originally a contraction of some word that denoted similitude, or participation; and indeed if we could examine language critically, we have no doubt that Mr. Tooke's theory might be demonstrated, and *all* of them proved to be originally words with a full meaning.

In the Hebrew, most adverbs, particularly those of quality, are expressed by nouns, both substantives and adjectives, either simply, or connected with a preposition.

ADVERSARIA, among the ancients, was a book of accounts, not unlike our journals, or day books. The word is more particularly used, among men of letters, for a kind of common place book, wherein they enter whatever occurs to them worthy of notice, whether in reading or conversation, in the order in which it occurs: a method which some persons prefer to that of digesting them under regular heads.

ADVERSATIVE, in grammar, is a word expressing some difference between what goes before and what follows it. Thus, in the phrase, *he loves knowledge but has no application*, the word *but* is an adversative conjunction; between which and a disjunctive one there is this difference, that the first sense may hold good without the second opposed to it, which is otherwise in regard to disjunctive conjunctions.

Mr. Tooke, in the book above quoted, observes well, that there are two senses to the word *but;* in the *first*, it is a corruption of *bot*, the imperative of the Saxon verb *botan, to boot, superadd* or *supply;* and in the *second*, it is a contraction of *be-utan, to be out;* in illustration of this theory is given the following couplet:

> "*But* thy work shall endure in laude and glorie,
> *But* spot or faulte condigne eterne memorie."

The meaning is "*superadd* (to something said before) thy work shall endure in laude and glorie; *be out* or *without* spot or faulte."

ADVERSATOR, in antiquity, a servant who attended the rich in returning from supper, to give them notice of any obstacles in the way, at which they might be apt to stumble.

ADVERTISEMENT is particularly used for a brief account of an affair inserted in the daily or other public papers, for the information of all concerned, or who may find some advantage from it. By the statute law the penalty of 50*l.* is inflicted on persons advertising a reward with "*no questions to be asked*," for the return of things lost or stolen. The same penalty attaches to the printer.

ADVICE, or *letter of* ADVICE, a letter missive, by which a merchant, or banker, informs his correspondent, that he has drawn a bill of exchange, that his debtor's affairs are in a bad state, or that he has sent a quantity of merchandise, whereof the invoice is usually annexed. A letter of advice for the payment of a bill of exchange should mention the name of the person for whose account it is drawn; the day, month, and year; the sum drawn for; the name of him from whom the value is received; and the person's name to whom it is payable.

For want of such advice it is very allowable to refuse accepting a bill of exchange.

ADVICE *boat*, a small vessel employed to carry expresses or orders with despatch.

AD VITAM *aut culpam*, denotes an office to be held *quamdiu se bene gesserit*, that is, till the death or some delinquency of the possessor.

ADULT, among civilians, denotes a youth between fourteen and twenty-five years of age.

ADULTERATION, in a general sense, denotes the act of debasing, by an improper mixture, something that was pure and genuine. Thus,

ADULTERATION *of coin*, is the casting or making it of a metal inferior in goodness to the standard, by using too great a proportion of alloy. This is a crime which all nations have made capital.

ADULTERATION, in pharmacy, is the using ingredients of less virtue in medicinal compositions, to save expense; a practice with which the dealers in medicine and drugs are but too well acquainted.

ADULTERATION, among distillers, vintners, &c. is the debasing of brandies or wines, by mixing them with some improper liquor.

By stat. 1. W. and M. c. 34. whoever sells adulterated wine, is to forfeit three hundred pounds. We have laws also against the adulteration of coffee, tea, tobacco, snuff, beer, bread, wax, hair powder, &c.

ADULTERY, the crime of married persons, whether husband or wife, who are guilty of a violation of their marriage vow.

By the law of Moses, both man and woman, who had been guilty of adultery, were put to death. The ancient Romans had no formal law against adultery; Augustus being the first who made it punishable by banishment, and in some cases by death. By an edict however of Antoninus, a husband could not prosecute his wife for adultery, unless he was innocent himself. And by the regulations of Justinian, at the instance of his wife Theodora, the punishment of adultery in the woman was mitigated; whipping, and shutting up in a convent for two years, being deemed sufficient, after which time, if the husband did not take back his wife, she was shut up for life. Among the Greeks, adultery was punished variously; sometimes by fine, and at others by what they called *paratilmus:* nay, the Lacedemonians are even said to have permitted it. Adultery among European nations is reckoned a private offence, none but the husband being

suffered to intermeddle in the affair; and what is no less remarkable, though the husband be guilty of adultery, the wife, except in Scotland, is not allowed to prosecute him for the same.

In England adultery is accounted a spiritual offence, and therefore the injured party can have no other redress but to bring an action of damages against the adulterer; and to divorce and strip the adulteress of her dower, is all the punishment she incurs. And, indeed, it must be owned, that the laying a heavy fine upon the man, and punishing the woman in the manner just mentioned, is as likely, if not more so, to prevent the frequency of adultery, as more severe methods.

ADULTERY is also used for any kind of unchastity; in which sense divines understand the seventh commandment.

ADULTERY, in the Scripture language, is likewise used for idolatry, or forsaking the worship of the true God for that of a false one.

ADUMBRATION, in heraldry, denotes the shadow of any beast or charge outlined, and painted of a darker colour than the field.

ADVOCATE, *advocatus*, among the Romans, a person who undertook the defence of causes, which he pleaded much in the same manner as our barristers do at present.

Advocates were held in great honour during the first ages of the Roman commonwealth, being styled *comites*, *honorati*, *clarissimi*, and even *patroni*. The term advocate is still retained in all countries where the civil law obtains. In Scotland there is a college of advocates, consisting of one hundred and eighty persons, appointed to plead in all actions before the lords of session. In France there are two kinds of advocates; or those who plead, and those who only give their opinions, like our chamber counsellors.

ADVOCATE, *lord*, one of the officers of state in Scotland, who pleads in all causes of the crown, or wherein the king is concerned. The lord advocate sometimes happens to be one of the lords of session; in which case he only pleads in the king's causes.

ADVOCATE, *fiscal*, *fisci advocatus*, in Roman antiquity, was an officer of state under the Roman emperors, who pleaded in all causes wherein the *fiscus*, or private treasury, was concerned.

ADVOCATES *consistorial*, officers of the consistory at Rome, who plead in all oppositions to the disposal of benefices in that court: they are ten in number.

ADVOCATE *of a city*, in the German polity, a magistrate appointed, in the emperor's name, to administer justice.

ADVOCATE, among ecclesiastical writers, a person who undertook the defence of a church, monastery, &c. Of these there were several kinds; as elective advocates, or those chosen by the chapter, bishop, abbot, &c. nominative advocates, or those appointed by the emperor, pope, &c. military advocates, those who undertook the defence of the church rather by arms than eloquence, &c. There were also feudal advocates, supreme and subordinate advocates; and matricular advocates, or those of the mother or cathedral church.

ADVOCATION, among civilians, the act of calling another to assist in pleading some cause.

ADVOCATION, *letters of*, in the law of Scotland, a writ issued by the lords of session, advocating, or calling, a cause from an incompetent judge to themselves.

ADVOCATIONE *decimarum*, a writ which lies for claiming a fourth part of tithes or upward belonging to any church.

ADVOWSON, in law, is the right of patronage, or presenting to a vacant benefice.

Advowsons are either appendant, or in gross. Appendant advowsons are those which depend on a manor or lands, and pass as appurtenances of the same; whereas advowson in gross is a right of presentation subsisting by itself, belonging to a person, and not to lands. Whenever the property of an advowson has been once separated from the property of the manor by legal conveyance, it never can afterward be re-united, but remains forever an advowson in gross. In either case, advowsons are no less the property of the patrons than their landed estate: accordingly, they may be granted away by deed or will, and are assets in the hands of executors. Papists, however, and Jews, seized of any advowsons, are disabled from presenting; the right of presentation being in this case transferred to the chancellors of the universities, or the bishop of the diocese.

ADYTUM, in pagan antiquity, the most retired and sacred place of their temples, into which none but the priests were allowed to enter. The term is purely Greek, signifying inaccessible.

ADZE, a kind of crooked ax, used by coopers, &c. otherwise called addice.

ÆACEA, in Grecian antiquity, solemn festivals and games celebrated at Ægina, in honour of Æachus; who, on account of his justice upon earth, was thought to have been appointed one of the judges in hell.

ÆCHMALOTARCHA, in Jewish antiquity, the title given to the principal leader or governor of the Hebrew captives residing in Chaldea, Assyria, and the neighbouring countries. The Jews themselves call this magistrate *Rosch-galuth*, *i. e.* chief of the captivity. Basnage assures us, that there was no æchmalotarch before the end of the second century: and Prideaux says, that the æchmalotarch, at present, is only the head of their religion, like the *episcopus Judæorum*, in England, the altarch at Alexandria, and the ethnarch at Antioch.

ÆDES, in Roman antiquity, signified an inferior kind of temple, consecrated indeed to some deity, but not by the augurs. There were a vast number of these in ancient Rome; thus we read of the *ædes fortunæ*, *ædes pacis*, *ædes Herculis*, &c.

ÆDICULA, a term used to denote the inner part of the temple, where the altar and statue of the deity stood.

ÆDILE, in Roman antiquity, a magistrate whose chief business was to superintend buildings of all kinds, but more especially public buildings; as temples, aqueducts, bridges, &c.

To the ædiles likewise belonged the care of the highways, public places, weights and measures, &c. They also fixed the prices of provisions, punished lewd women, and such persons as frequented gaming houses. The custody of the Plebiscita, or orders of the people, was likewise committed to them. They had the inspection of comedies, and other theatrical pieces; and were obliged to exhibit magnificent games to the people at their own expense, whereby many of them were ruined.

At first the ædiles were only two in number, and chosen from among the common people; but these being unable to support the expense of the public shows, two more were created out of the patrician order: these last took upon themselves all the charges of the games, and were called *ædiles curules*, or *majores*, as the two plebeians were denominated *minores*.

Julius Cæsar, in order to ease these four, created two others, who were called *ædiles Cereales*, as having the inspection of all manner of grain committed to their care.

There were also ædiles in the municipal cities, who had much the same authority as those in Rome.

ÆDILITIAN *edict*, among the Romans, was particularly used for the ædile's sentence, allowing redress to the purchaser of a beast or slave that had been imposed on.

ÆDITUUS, in Roman antiquity, an officer belonging to temples, who had the charge of the offerings, treasure, and sacred utensils. The female deities had a woman officer of this kind, called æditua.

ÆGAGROPILA, or ÆGAGROPILUS, in natural history, a ball composed of a substance resembling hair, generated in the stomach of the chamois goat. It is a kind of bezoar, called *bezoar germanicum*, and is possessed of no medicinal virtue, any more than the balls of the same kind formed in the stomachs of cows, hogs, &c. See BEZOAR.

ÆGIAS, among ancient physicians, a white speck on the pupil of the eye, which occasioned a dimness of sight, and was otherwise called *aigis* and *aiglia*.

ÆGICERAS, a genus of the class and order of the pentandria monogynia. The essential character is, calyx bell shaped, half five cleft; capsule bow shaped, one celled, gaping on the convex side; seed inverted. It is found in the Molucca islands, and in Ceylon. There are two species, the majus and minus.

ÆGILOPS, an abscess in the corner of the eye, next the nose; or, according to Heister, a small tumour caused by an inflammation or abscess, which in time, by the acrimony of its purulent matter, erodes the external skin, lachrymal ducts, and fat round the ball of the eye; sometimes it renders the neighbouring bones carious to a dangerous degree.

As to the method of treatment, the surgeon is first to endeavour to disperse the tumour, by moistening it several times a day with spirit of vitriol; but if he finds this impracticable, he is to forward the suppuration as much as possible, lest an obstinate fistula, or worse consequences, should be the effects of two long delay. For this purpose a plaster of diachylon with the gums, or emollient cataplasms, may be used. When fully ripe, the tumour is to be laid open with a lancet or scalpel, and the ulcer cleaned or healed in the ordinary way. See SURGERY.

ÆGILOPS, a genus of the polygamia and monoecia class and order, and of the natural order of grasses. The essential character is, calyx a glume, subtriflorous, cartilaginous; corolla a glume terminating in a threefold awn; stamina three; styles two; seed one.

There are four species of this grass, all of which seem to be annual. They grow in the southern parts of Europe.

ÆGIPHILA, a genus of the tetandria monogynia class and order, and the natural order of vitices. The corolla is salver shaped: and the essential character is, calyx four toothed; corolla quadrifid; style semibifid: berry four seeded.

There are four species; one a native of Martinico, the others of Jamaica. They are all shrubs of a moderate height.

ÆGIS, in heathen mythology, is particularly used for the shield or cuirass of Jupiter and Pallas.

ÆGOMANTIA, a species of divination performed by means of a goat.

ÆGOPHTHALMUS, the goat's-eye stone, in natural history, a name indifferently given to any of the semipellucid gems, with circular spots in them, resembling the eye of a goat.

ÆGOPODIUM, or *goat weed*, *herb gerard*, or *wild masterwort*, a genus of the pentandria digynia class and order, and of the natural order of umbellatæ, or umbelliferæ. The characters are, the universal calyx is a manifold convex umbel; the partial one, consimilar and flat; there is no involucrum, and the proper perianthium is scarcely discernible: the universal corolla is uniform, the florets all fertile; the proper one has five inverse, ovate, concave, equal petals, inflected at the top; the stamina consist of five simple filaments twice the length of the corolla: the antheræ roundish; the pistillum has a germen beneath; two purple erect styles the length of the corollet; the stigmata are headed; no pericarpium; the fruit is ovate, striated, and bipartite; the seeds are two, ovate, on one side convex and striated, and flat on the other.

There is but one species, a native of England, and other parts of Europe. It is very common under hedges and about gardens; the leaves resemble those of angelica, and it bears small white flowers.

ÆGOPRICON, a genus of the monoecia monandria class and order, the characters of which are: the calyx both of the male and female is a tubular perianthium of one leaf divided into three segments; corolla wanting in both; the stamina consist of a single erect filament longer than the calyx, with an ovate anthera; the pistillum has an ovate germen, three divaricated styli, the simple persistent stigmata, the pericarpium is a globular berry, three grained within, and three celled: the seeds are solitary, and angular on one side.

There is but one species, which is a branching tree, a native of Surinam.

ÆGYPTIACUM, the name of several detergent ointments, used for eating off rotten flesh, and cleansing foul ulcers.

The ægyptiacum, as ordered in the Edinburgh dispensatory, is a composition of verdigris, reduced to fine powder, five ounces; of honey, fourteen ounces; of vinegar, seven ounces: all which are to be boiled over a gentle fire, to the consistence of an unguent.

ÆGYPTILLA, in the natural history of the ancients, a stone variegated with veins of a black, blue, or red colour; and said to be capable of giving water the colour and taste of wine.

The stone to which they ascribed this imaginary virtue, seems to have been a kind of onyx, or sardonyx.

ÆINAUTÆ, in antiquity, a denomination given to the senators of Miletus, from holding their deliberations on board a ship, and never returning to land till matters had been agreed on.

ÆLURUS, in Egyptian mythology, the deity or god of cats; represented sometimes like a cat, and at others like a man with a cat's head.

ÆNEATORES, in Roman antiquity, a general name for the musicians of an army, *viz.* those who played on trumpets, horns, litui, buccinæ, &c.

ÆNIGMA, denotes any dark saying or question, wherein some well known thing is concealed under obscure language.

The parable, gryphus, and rebus, are by some accounted three species, or branches, of ænigma. To compose an ænigma, two things are to be chosen which bear some resemblance to each other, on which some perplexing and intricate question, description, or prosopopœia, is to be founded. This last is most pleasing, as it gives life and action to things destitute of them.

Painted ænigmas are representations of some object, whether of nature or art, concealed under the human figure.

ÆOLIC, in a general sense, denotes something belonging to Æolia or Æolis.

Æolic *dialect*, among grammarians, one of the five dialects of the Greek tongue, agreeing in most things with the Doric dialect.

Æolic *verse*, in prosody, a kind of verse, consisting of an iambus or spondee, then of two anapæsts separated by a long syllable. Such is,

O stelliferi conditor orbis!

ÆOLIPILE, a hollow metalline ball, in which is inserted a slender neck or pipe; whence, after the vessel has been partly filled with water, and heated, issues a blast of vapour with great vehemence.

Great care should be taken that the aperture of the pipe be not stopped when the instrument is put on the fire, otherwise the æolipile will burst with a vast explosion, and may occasion no little mischief.

The æolipile is sometimes placed on a small carriage, and a cork thrust into the extremity of the pipe. When the vapour is sufficiently heated, it rushes out with the cork in one direction, while the carriage moves the contrary way.

ÆOLUS's *harp*, an instrument so named from its producing an agreeable harmony, merely by the action of the wind. The construction of the instrument is as follows: Let a box be made of as thin deal as possible, its length exactly answering to the width of the window in which it is to be placed; it must be five or six inches deep, and seven or eight inches wide. Across the top, and about four inches from each end, glue a piece of wainscot half an inch high, and a quarter of an inch thick, to serve as bridges for the strings to be stretched over, by means of pins inserted into holes a little behind the bridges, nearer the ends; half the number being at one end, and half at the other. These pins are like those of a harpsichord; and, for their better support in the thin deal, a piece of beech, about an inch wide, is glued on the inside of the lid, immediately under the place of the pins, the holes for receiving them being bored through this piece. It is strung with fine catgut, or blue first fiddle strings, more or less, at pleasure, on the outside and lengthwise of the lid, fixing one end to one of the small pins, and twisting the other end about the opposite or stretching pin. Two sound holes are cut in the lid, and the thinner this is the better will be the performance.

When the strings are tuned in unison, and the instrument placed with the stringed side outward, in the window to which it is fitted, the air will cause the instrument to give a sound like a distant choir, increasing and decreasing according to the strength of the wind.

ÆON properly signifies the age or duration of any thing. Æon, among the Platonists, however, was used to denote any virtue, attribute, or perfection: hence they represented the Deity as an assemblage of all possible æons, calling it pleroma or fulness.

ÆORA, among ancient physicians, a peculiar kind of exercise, which consisted in being carried about in a litter or other vehicle. Sometimes the patient's bed was hung by ropes, in the manner of a hammock, and moved backward and forward. Travelling in a chariot, or on board a ship or boat, were also accounted so many kinds of æora.

ÆRA, in chronology, a series of years, commencing from a certain fixed point of time, called an epocha: thus, we say the Christian æra, that is, the number of years elapsed since the birth of Christ.

The generality of authors, however, use the terms æra and epocha in a synonymous sense, or for the point of time from which the computation commences; making no other difference between them, except that the former is chiefly used by the vulgar, and the latter by chronologers.

ÆRARIUM, in Roman antiquity, the treasury, or place where the public money was deposited. Ærarium and fiscus are sometimes used in a synonymous sense; though the latter, strictly speaking, contained only the money belonging to the emperor.

Ærarium *sanctius*, an appendage added to the former, for containing the monies arising from the twentieth part of all legacies, which was kept for the extreme necessities of the state.

Ærarium *privatum*, was the emperor's privy purse, or place where the monies arising from his private patrimony were deposited.

Ærarium *Ilithiæ*, or *Junonis Lucinæ*, one where the monies were deposited, which parents paid for the birth of each child. There are several other treasuries mentioned in historians, as the *ærarium juventutis*, *Veneris*, &c.

ÆRARIUS was used by the Romans for a degraded citizen, whose name had been struck off the list of his century. The *ærarii* were so called on account of their being liable to all the taxes and other burdens of the state, without enjoying any of its privileges. Hence, *inter ærarios referri* was a great deal more severe punishment than *tribu moveri*.

AERATION *of soils* denotes the impregnation of them with air, by means of ploughing, harrowing, and other means of pulverization, which serve to introduce the air into the pores of the earth.

AERIAL ACID, a name given by Bergmann to carbonic acid gas. (*a*)

AERIANS, a branch of Arians, who to the doctrines of that sect added some peculiar dogmas of their own; as, that there is no difference between bishops and priests; a doctrine maintained by many modern divines, particularly of the presbyterian and reformed churches.

AEROLOGY is a scientifical account of the nature and less obvious properties of air. See Air.

AEROMETRY, the art of measuring the motion, gravity, elasticity, rarefaction, condensation, &c. of air; in which sense aerometry is synonymous with pneumatics, a term in more common use. See Pneumatics.

AERONAUTICA denotes the art of sailing through the air, as a ship in the sea. This, however fanciful it was formerly accounted, has been lately reduced to a reality. See Air Balloon.

AEROPHOBIA, among physicians, signifies the dread of air, which is a symptom of phrensy. Dr. Franklin says he has sometimes been seized with *aerophobia*, but experience soon convinced him that fresh air is eminently conducive to health. Any air, he says, is preferable to that of a close chamber, which has been again and again respired without change.

AEROPHYLACEA, a term used by some naturalists for certain caverns or reservoirs of air, supposed to exist in the bowels of the earth, by means of which they account for the origin of springs.

AEROSTATION. See Air Balloon.

ÆRUGINOUS, an epithet given to such things as resemble, or partake of the nature of, the rust of copper. Thus, an æruginous colour is green, or that of verdigris.

ÆRUGO *salis*, a kind of reddish slimy matter, separated from the Egyptian *natrum;* probably a mixture of bitumen and a red earth.

ÆRUSCATORES, in antiquity, a kind of strolling beggars, not unlike gypsies, who drew money from the credulous by fortune telling and juggling.

The priests of Cybele were called *æruscatores magnæ matris*, on account of their begging in the streets; for which purpose they had little bells thereby to draw people's attention to them, much like some orders of mendicants abroad.

Æruscatores was also a denomination given to griping exactors, or collectors of the revenue.

ÆS, properly signifies copper, or money coined of that metal. Authors speak of *æs rude*, *æs grave*, and *æs signatum*. Some suppose the two former to denote the same thing, *viz.* money paid by weight and not by tale, as the *æs signatum*, or coined money, was. Others again consider the *æs grave* to have been large pieces of coined copper, containing a whole *as*, or pound weight. Kuster, on the other hand, thinks that *æs grave* was used to denote any kind of copper money, in opposition to that made of gold or silver, which was light.

Æs *flavum*, yellow copper, among the Romans, an appellation given to the coarser kinds of brass, the finest being called *orichalcum*. See Brass and Orichalcum.

Æris *flos*, among ancient alchymists, a kind of small scales procured from melted copper, by exposing it to a vehement heat: but among the moderns it is sometimes used for *ærugo* or verdigris.

Æs *ustum*, among chymists, a preparation of copper, otherwise called *æs veneris*, *æs crematum*, &c. There are several ways of making it; but the most frequent is, by exposing plates of copper in a reverberatory furnace till they will crumble into a powder, which is called *æs ustum:* this is extremely drying and detersive, and therefore used for eating off dead flesh, and cleansing foul ulcers; and either sprinkled on the part in powder, or mixed in ointments. It is also used for colouring glass.

Æs. *Per æs et libram*, was a formula in the Roman law, by which purchases and sales were ratified. The phrase was originally used in speaking of things sold by weight, or by scales, but it was afterward used on other occasions. Hence, in *adoptions*, the formula expressed that the person adopted was bought per *æs et libram*.

ÆSCHYNOMENE, or Bastard Sensitive Plant, a genus of the class and order diadelphia decandria. The corolla is papilionaceous; and the essential character is, calyx bilobate, legume with truncate one seeded joints.

It is a shrubby plant, and includes eight species, all exotics. Four species, the Æ. aspera, Americana, Indica, and pumila, are annual plants. Only two of the species appear to be sensitive, *viz.* the Æ. Americana and sensitiva. The others are chiefly cultivated for their beautiful flowers; the legumes of some of the species are a foot and a half, and two feet long. The Æ. cannabina, which is a native of the East Indies, treated as hemp, may be used as such. They are all very tender stove plants in this country.

ÆSCULUS, horse chesnut, a genus of the heptandria monogynia class and order, or the natural order of trihilatæ. The essential character is, calyx one leafed, five toothed, ventricose; corolla five petalled, irregularly coloured, inserted into the calyx; capsule three celled.

The genus embraces three species. The common horse chesnut is well known. On its first introduction into this country, rather more than a century ago, from its very quick growth, it was more cultivated than it deserved. It is now found that it will seldom resist a great storm of wind; and the very short time its leaves continue, renders it unsightly a great part of the year; yet it must be confessed that its form is regular, and its blossoms beautiful. The wood is of little use but for burning, though it is said that it is now employed by the turners. The nuts are eaten by deer, and Hanbury affirms that hogs will fatten on them: Haller also relates, that sheep have been fed with them whole, and poultry with them when boiled. The yellow and scarlet horse chesnut are cultivated for the beauty of their flowers.

ÆTATE probanda, in law, a writ which formerly lay to inquire whether the king's tenant was of full age; but now disused, since the abolition of wards and liveries.

ÆTHER, a term used by some philosophers for the most subtile of all fluids, which, commencing from the limits of our atmosphere, was thought to pervade the vast expanse of heaven.

Authors differ widely with respect to its nature; some making it a finer kind of air, others a kind of fiery effluvium from the sun and fiery stars, and others a fluid *sui generis*.

Æther is supposed by some philosophers not only to fill up the intermediate space between the heavenly bodies, but to permeate all bodies whatever; also to be the medium of light; and, lastly, that it was the cause of gravity in the earth and other celestial bodies, assisted in the action of burning, and in the dissolution of other bodies, by menstruums. After all, modern philosophers make it a question whether there is any such fluid.

Æther or Ether, is more particularly used for an extremely volatile spirit, made by distilling alcohol with

an acid, and then precipitating the acid gas with an alkali.

The properties of the æther obtained are supposed to vary a little according to the acid employed: accordingly every particular kind is distinguished by the acid employed in its preparation. Thus the æther obtained by means of sulphuric acid is called *sulphuric æther;* that by means of nitrous acid, *nitrous æther.*

1. Sulphuric æther is usually prepared by the following process: A mixture of equal parts of alcohol and sulphuric acid is put into the retort, to which a large receiver is then luted. It is proper to surround the receiver with ice, or at least with cold water. Heat is applied; and as soon as the mixture boils, the æther comes over and is condensed, and runs in large striæ down the sides of the receiver. As soon as it amounts to one half of the alcohol employed, the process must be stopped. The æther thus obtained is not quite pure, almost always containing a little sulphureous acid.

This acid may be separated by pouring the æther on a little potash, and distilling it over again by means of a moderate heat. Mr. Dize affirms that black oxide of manganese produces this effect still more completely than potash. All that is necessary is, to mix a quantity of this black oxide in powder with the impure æther, and to let it remain for some time, agitating it occasionally. The sulphureous acid is converted into sulphuric, and combines with the manganese. The æther is then to be distilled over by the heat of a water bath.

The separation of the liquid from the sulphureous acid, with which it is mixed, is called the *rectification of the æther.* The usual method, and we may add the best, is the following, first employed by Mr. Woulfe: Fill three fourths of a bottle with the impure æther, add a little water, and a portion of slacked lime. Agitate the bottle with violence, and keep it for some time in water before taking out the cork. If the smell of the acid is not removed, add a little more lime, and agitate a second time. Decant off the æther into a retort, and distill it over.

2. Æther thus obtained is a limpid and colourless liquor, of a very fragrant smell, and a hot, pungent taste. Its specific gravity is only 0.7581.

It is so volatile that it can scarcely be poured from one vessel to another without losing a considerable portion of it by evaporation. When poured out in the open air, it disappears in an instant, and during its evaporation produces a very considerable degree of cold. If a glass vessel containing water, and surrounded with a cloth, is dipped into æther two or three times, and the æther each time allowed to evaporate from the cloth, the water in the glass freezes. In the open air æther boils at 98°, and in a vacum at —20°. Were it not, therefore, for the pressure of the atmosphere, it would always exist in the gaseous state.

It is exceedingly inflammable, and when kindled in the state of vapour, burns with rapidity, with a fine white flame, and leaves behind it a trace of charcoal. During its combustion carbonic acid is generated. How well soever it has been rectified, it always exhibits traces of sulphuric acid.

When æther in the state of vapour is made to pass through a red hot porcelain tube, it is decomposed completely, and a great quantity of carburated hydrogen gas is obtained.

Æther, when exposed to a cold of —46°, freezes and crystallizes.

3. Æther is soluble in 10 parts of water, according to the count de Lauraguis.

4. When æther is admitted to any gaseous body standing over mercury, it always doubles the bulk of the gas, as Dr. Priestley first observed. If oxygen gas, thus expanded by æther, is presented to a lighted candle, the æther burns with great rapidity, but produces no explosion. But if one part in bulk of this expanded oxygen is mixed with three parts of pure oxygen gas, and kindled, a very loud explosion takes place: the products are water and $2\frac{1}{2}$ parts of carbonic acid. Mr. Cruikshank, to whom we are indebted for this instructive experiment, ascertains, that one part of the vapour of æther takes 6.8 parts of oxygen gas to consume it completely; and from the relative proportions of the two products, he has shown that the carbon which æther contains is to its hydrogen as 5 to 1.

5. The action of the simple combustibles on æther has not been tried, if we except phosphorus, which it is capable of dissolving in small proportion. The solution is transparent; but the addition of a little alcohol to it renders it milky. This furnishes us with a method of ascertaining whether æther is sophisticated with alcohol.

6. Æther has no action on metals; but it revives several of the metallic oxides when mixed with their solutions in acids. It takes gold from its solution in nitro muriatic acid.

7. It is probable that it has no action on fixed alkalies and earths; but it combines, or at least mixes readily, with ammonia.

It absorbs nitrous gas in considerable quantity.

8. Sulphuric acid seems capable of converting it into a peculiar kind of oil, known by the name of sweet oil of wine.

If we fill a bottle, capable of holding three or four English pints, with oxymuriatic acid gas, taking care to expel the water as completely as possible, and then throw into it about a dram or half a dram of good æther, covering its mouth immediately with a piece of light wood or paper, in a few seconds white vapour will be perceived moving circularly in the bottle: this will be soon followed by an explosion accompanied with flame; at the same time a very considerable quantity of charcoal will be deposited, and the bottle will be found to contain carbonic acid gas.

Æther is capable of dissolving the volatile oils. It combines with alcohol in almost any proportion.

The method of preparing *nitrous æther,* proposed by Navier, was this: twelve parts of alcohol are put into a strong bottle, which is kept surrounded with water, or rather with ice: eight parts of nitric acid are poured in at intervals, the mixture being agitated after every addition. The bottle is then well corked, and the cork secured by leather. Æther gradually forms at the surface of the liquid. After five or six days, when the formation is supposed to be over, the cork is to be pierced with a needle to allow a quantity of nitrous gas to escape, which would otherwise carry the æther along with it. The cork is then to be drawn; the whole liquid is to be poured into a funnel, and by means of the finger the liquid below is allowed to run out while the æther is retained.

This method is somewhat hazardous; for the quantity of nitrous gas evolved is so great as often to burst the

bottle. Dr. Black substituted in place of it a very ingenious process. He put into a glass phial the proper quantity of nitric acid; over this was poured gently a stratum of water, and the alcohol was poured over all. Thus there were three strata of liquids in the vessel; the acid lowermost, and the alcohol uppermost, separated from each other by the water. The acid and alcohol gradually combined with the water, and coming into contact acted on each other without violence; and thus the æther was formed without risk.

Dehne has given another process for obtaining nitric æther exceedingly tedious, but not attended with any risk. The alcohol is put into a tubulated retort, to which a large receiver is luted: one 48th part of nitric acid is to be added every four hours, drop by drop, till it amounts to about one half of the weight of alcohol; then the mixture becomes hot, and æther passes over into the receiver. After this a little more nitric acid is to be added every morning and evening. Æther gradually forms on its surface. The acid is to be added till it falls down to the bottom of the retort in the form of green globules, indicating the formation of perfectly saturated nitrous acid. This is a proof that no more æther will be formed.

Various other methods of preparing nitrous æther have been proposed by chymists; as the distillation of a mixture of sulphuric acid, nitre, alcohol, &c. But the process preferred by artists is that of Chaptal as corrected by Proust. A large retort is luted to a glass globular vessel furnished with a tube of safety. From this globe a tube passes to a second, likewise furnished with a tube of safety; and to this last vessel are connected three Woulfe's bottles in the usual way, which must be half full of alcohol. A mixture of 32 parts of alcohol and 24 of acid, of the specific gravity 1.3, is put into the retort. The heat of a chafingdish is applied, and removed as soon as the effervescence begins. The greatest part of the æther is detained by the alcohol in the first Woulfe's bottle. This mixture is to be saturated with an alkali, and the æther separated by distillation.

Nitrous æther, by whatever process it is procured, is never pure at first, holding always in solution a considerable portion of nitrous gas: hence its extraordinary volatility. It contains also a certain portion of nitric acid, and a little oil to which it owes its yellow colour. The nitrous gas separates spontaneously when the æther is mixed with a considerable portion of water. By distilling it repeatedly from potash or sugar, the oil may be abstracted; and when kept for some time, the nitric acid is decomposed, and a little water and oxalic acid formed, which sink to the bottom of the vessel.

Nitric æther, as far as is known, agrees very nearly in its properties with sulphuric æther: it is equally fluid, light, and combustible: its state and odour are nearly the same, but not quite so pleasant, owing most probably to the foreign bodies, from which it cannot easily be completely freed.

According to Mess'rs. Fourcroy and Vauqulin, æther is composed of the same ingredients as alcohol, but combined in different proportions. According to them, æther contains a greater proportion of dydrogen and oxygen, and a smaller proportion of carbon, than alcohol.

ÆTHIOPS, or Æthiops mineral, or Hydrargyrus *cum sulphure*, a preparation of mercury, made by rubbing in a marble or glass mortar, equal quantities of quicksilver and flowers of sulphur, till the mercury wholly disappears, and there remains a fine deep black powder, whence it has got the name of æthiops, and it is much used in medicine. The name is changed in modern pharmacy to that of hydrargyrus cum sulphure.

Æthiops *antimonialis*, a combination of the sulphurets of antimony and mercury; it is prepared by fusing crude antimony in an earthen crucible, and when it is on the point of fixing, add to it an equal weight of hot mercury: the mixture at first becomes more fluid, and after a while solid: when cold it must be levigated in a mortar and washed. The medical effects of this preparation in small quantities are sudorific; in larger doses it is a purgative and emetic.

Æthiops *vegetabilis* is prepared by burning the sea wrack or sea oak in the open air, and then reducing it into a black powder. It is used to reduce scrofulous swellings, and in cleansing the gums and teeth.

ÆTHUSA, a genus of the pentandria digynia class and order, belonging to the natural order of umbellatæ or umbelliferæ.

The calyx is an universal umbel expanding, the interior rays shorter by degrees; with a partial umbel, small and expanding. There is no universal involucrum; the partial one is dimidiated with three or five leaflets, and pendulous; the proper perianthium scarcely discernible. The universal corolla is uniform, with fertile florets; the partial one has five heart inflected unequal petals. The stamina consist of five simple filaments, with roundish antheræ. The pistillum is a germen beneath, with two reflected styli; the stigmata obtuse. There is no pericarpium; the fruit is ovate, striated, and tripartite. The seeds are two, roundish, and striated. There is but one species, *viz.* the æthusa synapium, fool's parsley, or lesser hemlock, a native of Britain, which grows in corn fields and gardens. This plant, from its resemblance to common parsley, has sometimes been mistaken for it; and when eaten, it occasions sickness. If the curled leaved parsley only was cultivated in our gardens, no such mistakes would happen in future. Cows, horses, sheep, goats, and swine, eat it. It is noxious to geese.

AETIANS, in church history, a branch of Arians, who maintained that the Son and Holy Ghost are in all things dissimilar to the Father.

ÆTIOLOGY is a figure of speech, whereby, in relating an event, we at the same time unfold the causes of it.

ÆTITÆ, or Ætites, a name given to pebbles or stones of any kind, which have a loose nucleus rattling within them, and called in English the eagle stone. So far from being a particular genus of fossils themselves, we find ætitæ among very different genera, but the most valued is that formed of the several varieties of our common pebbles. As to the formation of ætitæ, the naturalists account for it from this consideration, that as the nuclei are coarser and more debased by earth than the rest of the pebble, they shrink and contract themselves into a smaller size; by which means they will be separated from the surrounding crust, and become loose.

ÆTNA, a famous volcanic or burning mountain in Sicily. It is one of the highest mountains of the whole island, and situated on the eastern coast, not far from Catania.

The height of this mountain is said to be above ten thousand feet above the surface of the sea, and its circumference at the base one hundred and eighty miles. This may probably be exaggerated; but over the sides there are seventy-seven cities, towns, and villages, and allowing from twelve to fifteen hundred persons to each, the number of inhabitants of mount Ætna will be from 92,400 to 115,500. The ascent of this mountain is tedious, difficult, and dangerous. From Catania to the summit, the distance is about thirty miles, and the traveller must pass through three distinct climates, which may properly be denominated the torrid, the temperate, and the frigid.

ÆTNA SALT, a name used by some writers for saline substances, found near the openings of mount Ætna, and other volcanos; being a concrete of sulphur and nitre, sublimed together.

ÆTOLARCHA, in Grecian antiquity, the principal magistrate or governor of the Ætolians.

AFFA, a weight used on the gold coast of Guinea, and equal to an ounce.

AFFECTIO *bovina*, a disorder incident to cattle, occasioned by a small worm, which eats its way all over the body.

AFFEERERS, or AFFEERORS, in law, persons appointed in courts leet, courts baron, &c. to settle upon oath the fines to be imposed upon those who have been guilty of faults which have no express penalty assigned by statute.

AFFETTUOSO, or *con* AFFETTO, in the Italian music, intimates that the part to which it is added ought to be played in a tender, affecting way; and consequently rather slow than fast.

AFFIDATIO DOMINORUM, in old law books, denotes an oath of allegiance, taken by the lords in parliament.

AFFIDAVIT is an oath in writing, taken before some person who is legally authorized to take the same.

In an affidavit, the time, place of habitation, and addition, of the person who makes it, are to be inserted.

Affidavits should set forth the matter of fact to be proved, without taking any notice of the merits of the cause. They are read in court upon motions, but are not admitted in evidence at trials.

By statute, the judges of the courts at Westminster may commission persons in the several counties in England to take affidavits relating to any thing depending in their several courts; but there is an affidavit office in the court of chancery, under the direction of a master.

AFFINITY, *affinitas*, among civilians, denotes the relation of each of the parties married to the kindred of the other. Affinity is distinguished into three kinds: 1. Direct affinity, or that subsisting between the husband and his wife's relations by blood, or between the wife and her husband's relations by blood. 2. Secondary affinity, or that which subsists between the husband and his wife's relations by marriage. 3. Collateral affinity, or that which subsists between the husband and the relations of his wife's relations. The degrees of affinity are always the same with those of consanguinity. Hence, in whatever degree of consanguinity the kindred of one of the parties married are, they are in the same degree of affinity to the other.

By the canon law, direct affinity renders marriage unlawful to the fourth generation, inclusive; but the case is otherwise with respect to the secondary and collateral kinds. It is likewise to be observed, that the affinity contracted by a criminal commerce, is an impediment to marriage so far as the second generation: thus, a man is not allowed to marry the sister of a woman he has lain with. Nay, with regard to contracting marriage, affinity is not dissolved by death; for, though a woman may be admitted a witness for the brother of her deceased husband, she is not allowed to marry him.

In the Romish church, a kind of spiritual affinity is supposed to be contracted by baptism; so that it is not deemed lawful for a god-father to marry his god-daughter without a dispensation.

AFFINITY, *chymical*, denotes an attractive power by which substances of different natures will combine with others. It is sometimes called *elective attraction*, or *elective affinity*. See CHYMISTRY.

AFFIRMATION is used for the ratifying or confirming the sentence or decree of some inferior court: thus, we say, the house of lords affirmed the decree of the lord chancellor, or the decree of the lords of session.

AFFIRMATION also denotes a solemn attestation of the truth of some fact which the quakers are allowed to make instead of an oath. This sect hold all kinds of swearing to be unlawful; and therefore the legislature has appointed the following affirmation to be taken instead thereof, *viz. I, A. B. do sincerely, solemnly, and truly declare and affirm*, &c. This affirmation is by statute put upon the same footing with an oath; every person convicted of affirming a falsehood, being liable to the penalties provided against wilful and corrupt perjury. It is also deemed equivalent to an oath, except in criminal cases, upon juries, and in places of profit or trust under the government.

AFFIRMATIVE, in the Roman inquisition, is a designation given to such heretics as openly avow the opinions they are charged with.

AFFIX, among grammarians, denotes much the same with prefix. In the Hebrew language there are a multitude of affixes, *i.e.* single letters or syllables, which, being prefixed to nouns and verbs, serve instead of pronouns and particles, and contribute greatly to the brevity of that language.

AFFLATUS, among heathen mythologists and poets, denotes the actual inspiration of some divinity. Thus Virgil:

> Afflata est numine quando
> Jam propriore Dei.

Tully, however, must be understood to extend the meaning of the word further, when he attributes all great actions to a divine *afflatus*.

AFFRAY, or AFFRAYMENT, in law, formerly signified the crime of affrighting other persons, by appearing in unusual armour, brandishing a weapon, &c. But at present, affray denotes a skirmish or fighting between two or more; and there must be a stroke given, otherwise it is no affray. It must also be public, for in private it is not an affray but an assault.

An affray is a common injury, punishable by the justices of the peace in their sessions, by fine and imprisonment.

A constable may also seize and carry affrayers before a justice, or confine them till they provide sureties for the peace. Any private person may also part an affray, or bring the parties before a magistrate.

AFFRONTE'E, in heraldry, an appellation given to animals facing one another on an escutcheon, a kind of bearing which is otherwise called *confrontée*, and stands opposed to *adossée*.

AFFUSION, in medicine, a term at present much used to express a very efficacious method of applying cold, by dashing cold water, lately recommended and practised with success, for allaying feverish heat, by Dr. Wright and Dr. Currie. (*a*)

AFRICA, one of the quarters of the world. See GEOGRAPHY.

AFRICAN *company*, a society of merchants established by king Charles II. for trading to Africa: which trade is now laid open to all his majesty's subjects, paying ten per cent. for maintaining the forts.

AFRICAN *association*, was formed in 1788, with a view of promoting the discovery of the interior parts of Africa. Mr. Mungo Parke, among others, was employed in this important work.

AFT, in the sea language, the same with abaft.

AFTER *birth*, in midwifery, the membranes which surrounded the infant in the womb, more usually called the secundines. See MIDWIFERY.

AFTER *math*, in husbandry, signifies the grass which springs or grows up after mowing; or the grass or stubble cut after corn. In some counties it is called rowen.

AFTER *pains*. See MIDWIFERY.

AGA, in the Turkish language, signifies a great lord or commander. Hence the aga of the janizaries is the commander in chief of that corps; as the general of the horse is denominated spahiclar aga. The aga of Algiers is president of the divan or council.

AGAPÆ, or AGAPES, love feasts kept by the ancient Christians as tokens of brotherly charity and mutual benevolence.

AGAPANTHUS, a genus of the hexandria monogynia class and order. This is the African tuberose hyacinth, or African blue lily, with an umbellated flower. The corolla is one petalled and funnel shaped, hexapetaloid, regular, and this forms its essential character.

We have only one species, the flowers of which are absolutely those of the hemerocallis, but this genus is distinguished by its spathe. It is a native of the Cape of Good Hope, was cultivated at Hampton court in 1692; but now forms a frequent and most beautiful ornament of our green houses. It flowers in September, and continues a long time in bloom.

AGAPETÆ, an order of nuns among the primitive Christians, who attended on and served the clergy. At first there was nothing scandalous in these societies, though they gave great offence afterward, and were wholly abolished by the council of Lateran, in 1139.

AGAPIS *lapis*, a name given by ancient writers to a stone of the colour of the lion's skin; it was held in great esteem in many nations on account of its supposed virtues.

AGARICUS, the mushroom, a genus of the cryptogamia class and order of fungi. The generic character is a pileus, or cap with gills underneath: gills differing in substance from the rest of the plant, composed of two laminæ: seeds in the gills.

Authors have enumerated no less than 634 species of this fungus, and Dr. Withering gives 213 as British species. The agaricus campestris, or common mushroom, is cultivated with great success and profit in the gardens about London. The spawn is usually found in old hot beds, or horse dung, where the animals have been fed on a pasture; in which case it is supposed that the invisible seed which is scattered from the gills of the mushroom, is eaten with the grass by the cattle, and deposited unhurt in their excrements. There it vegetates, and forms those white fibrous radicals producing tubercles like potatoes, and which are called the spawn. The spawn may easily be known by the smell, which resembles that of the true mushroom, and which, if planted in a bed of fresh hot dung, and kept moderately dry, will soon produce a crop. It is the agaricus orcades, another of this genus, which produces the fairy rings so frequently observed in pasture fields. The agaricus cæsareus, the most spendid of all the genus, is eatable, but is rarely found in Britain. It was made the vehicle for conveying poison to Claudius Cæsar by his wife Agrippina.

AGATE, in natural history, a genus of semipellucid gems, variegated with veins and clouds, but no zones, like the onyx.

The Iceland agate is found either in detached masses, or forming a part of rocks. It has the appearance of black glass. It is usually invested with a gray or opaque crust. Its specific gravity is 2,348; colour black, or grayish black; when in very thin pieces it is green. It is composed, according to Bergmann, of

69	silica
22	alumine
9	iron
100	

It is found in Iceland, Italy, and other places.

AGATE is also the name of an instrument used by the gold wire drawers; so called from the agate in the middle of it, which forms its principal part.

AGATHOPHYLLUM, a genus of the class and order dodecandria monogynia. The essential character is, calyx superior, very short, toothless; corolla six petalled, somewhat villous; stamina alternately inserted into the calyx and petals; drupe juiceless with a half six celled nut, and one seed.

There is but one species, a large tree, a native of Madagascar, where the nut and leaves are used as spice.

AGAVE, a genus of the hexandria monogynia class and order, called also the American aloe.

The corolla is funnel shaped, and the essential character is, corolla erect, superior; filaments longer than the corolla, erect. The species are six, including some varieties with striped leaves, of which the most remarkable is agave Americana, or great American aloe. It is a vulgar notion that this plant does not flower in less than a hundred years. The fact is, that its flowering depends upon its growth. In hot climates therefore it is known to bloom much sooner, and in this country, if it was kept in a dry stove instead of a green house, we have no doubt that it would flower earlier than it does. It is chiefly remark-

able for the height to which the stem shoots up when it blooms, from twenty to thirty feet, for in our opinion there is no beauty whatever in the flower. Cortusus is said to be the first European who possessed this plant in 1561. It flowered in England about the year 1698, and now scarcely a summer passes without one flowering in some of the nurseries about London. In the course of the year 1805, one of the striped leaved, said to be the first which ever flowered in England of that variety, was exhibited by Mr. Smith of Dalston.

In Spain and Portugal there are hedges of the great agave. The leaves are said to answer all the purposes of soap, and are also good for scouring pewter and other utensils; the inward spongy substance of the dried stalks may be used for tinder; and the fibres of the leaves, when washed, dried, and beaten, will make a strong thread for common purposes.

AGE is sometimes used in the same sense as generation, for a period of 30 years.

Age, in chronology, denotes certain periods of the duration of the world. Thus, among Christian chronologers, we meet with the age of the law of nature, which comprehends the whole time between Adam and Moses; the age of the Jewish law, which includes the time from Moses to Christ; and, lastly, the age of grace, or the number of years elapsed since the birth of Christ.

Among ancient historians, the duration of the world is also subdivided into certain periods, called ages; of which they reckon three: the first, reaching from the creation to the deluge which happened in Greece, during the reign of Ogyges, is called the obscure or uncertain age; the history of mankind, during that period, being altogether uncertain. The second, called the fabulous or heroic, terminates at the first olympiad; where the third, or historical age, commences. The ancient poets also divide the duration of the world into four ages, or periods; the first of which they called the golden age, the second the silver age, the third the brazen age, the fourth the iron age. Not unlike these are the four ages of the world, as computed by the East Indians, who extend them to a monstrous length.

Age also denotes certain degrees or periods of human life, commonly reckoned four, *viz.* infancy, youth, manhood, and old age: the first of which extends to the fourteenth year; the second, to the twenty-fifth year; the third, to the fiftieth year; and the fourth to the seventy-fifth year, or rather as long as a man lives. Shakespeare divides the term of life into seven ages.

Age, in law, signifies certain periods of life, when persons of both sexes are enabled to do certain acts, which for want of years and discretion they were incapable of before: thus a man at twelve years of age, ought to take the oath of allegiance to the king; at fourteen, which is his age of discretion, he may marry, choose his guardian, and claim his lands held in socage. Twenty-one is called full age, a man or woman being then capable of acting for themselves, or managing their affairs, making contracts, disposing of their estates, &c. which before that age they could not do. By the marriage act, no person, man or woman, can marry before 21, without the consent of parents or guardians. A woman is dowable at nine years of age, may marry at twelve, with consent of parents or guardian, and at fourteen choose her guardian. If a man or woman acts in any of the above mentioned capacities, before the time prescribed by law, he or she may retract at that time, otherwise they are supposed to agree to it anew, and it shall be deemed valid. Thus, if a man marries before fourteen, or a woman before twelve, they may either agree to the marriage, or not, at these several ages; and so in other cases. At fourteen a person may dispose of a personal estate by will, but not of lands.

Age *prier, ætatem precari*, is when an action being brought against a person under age, for lands descended to him, he, by motion or petition, shows the matter to the court, praying the action may be staid to his full age: to which the court generally agrees. As a purchaser, however, a minor shall not have his age prier; nor in any writ of assize, of dower, or petition; but he may in any action of debt. By the civil law the case is otherwise, an infant or minor being obliged to answer by his tutor or curator.

Among the Romans it was unlawful to offer for any public office or magistracy, unless the candidate had attained to a certain age; which differed according to the offices sued for. Hence the phrases consular age, prætorian age, &c.

Age *of the moon*, the time elapsed since her last conjunction with the sun. See Astronomy.

AGEMA, in Macedonian antiquity, was a body of soldiery, not unlike the Roman legion.

AGEMOGLANS, Agiamoglans, or Azamoglans, in the Turkish customs, Christian children raised every third year, by way of tribute, from the Christians tolerated in the Turkish empire. The collectors of this odious tax used to take one child out of three, selecting always the handsomest.

AGENTS, among physicians and chymists, an appellation given to all kinds of menstruums.

Agents *of bank and exchange*, in the commercial polity of France, are much the same with our exchange brokers.

Agent *and patient*, in law, is said of a person who is the doer of a thing, and also the party to whom it is done. Thus, if a man who is indebted to another, makes his creditor his executor, and dies, the executor may retain so much of the goods of the deceased, as will satisfy his debt; by which means he becomes agent and patient; that is, the person to whom the debt is due, and the person who pays it.

AGENTES *in rebus*, in antiquity, signifies officers employed under the emperors of Constantinople, and differing only in name from the *frumentarii*, whom they succeeded.

AGER, in Roman antiquity, a certain portion of land allowed to each citizen. It is also used, in middle age writers, for an acre of land.

AGERATUM, a genus of the class and order syngenesia polygamia æqualis. The corolla is compound uniform; and the essential character is, receptacle naked; down five awned; calyx oblong, subequal; corollets quadrifid.

There are two species, natives of South America and China. They are of the description of tender annuals.

AGERATUS *lapis*, a stone used by the ancients in dying and dressing of leather: possibly a species of pyrites.

AGGER, in the ancient military art, a bank or rampart, composed of various materials, as earth, boughs of trees, &c. The agger of the ancients was of the same nature with what the moderns call lines.

AGGER was also used in several other senses: as for a wall or bulwark, to keep off the sea: for the middle part of a military road, usually raised into a ridge; and sometimes for the heaps of earth raised over graves, more commonly called *tumuli*.

AGGLUTINANTS, a class of strengthening medicines, of a glutinous or viscous nature; which, by readily adhering to the solids, contribute greatly to repair their loss. They may be divided into two kinds: 1. Good nourishing food, especially jellies, whether of hartshorn, veal, mutton, &c. 2. Medicines, properly so called.

AGGLUTINATION, among physicians, signifies either the adherence of new substance, or the giving a glutinous consistence to the animal fluids, by which they were supposed to become more fit for nourishing the body.

AGGLUTINATION is also a term used by astronomers to denote the meeting of two or more stars in the same part of the zodiac, or the seeming coalition of several stars. It is more peculiarly understood of the seeming coalition of several stars, so as to form a nebulous star.

AGGRAVATION in the Romish canon law is used for an ecclesiastical censure, threatening excommunication, after three admonitions used in vain. From aggravation, they proceed to re-aggravation, which is the last *excommunication*.

AGGREGATÆ *terræ*, the seventh order of earths, comprehending those that are formed of the aggregate earths of the preceding orders. To this order belong the granites, gneissum, porphyrias, amygdalites, breccia, and arenarius.

AGGREGATE, a term used in botany to express those flowers which are composed of parts or florets, so united or incorporated by means either of the receptacle or calyx, that no one of them can be taken away without destroying the form of the whole.

AGGREGATION, in natural philosophy, denotes a species of union, by which several things, nowise connected by nature, are collected together, so as to form one whole.

AGIADES, in the Turkish armies, a kind of pioneers, employed in fortifying camps, &c.

AGILD, or AGILDE, in old law books, denotes a person of so little account, that whoever killed him was liable to no fine for so doing.

AGIO, in commerce, a term chiefly used in Holland and at Venice, where it denotes the difference between the value of bank stock, and the current coin.

Money in bank is commonly worth more than specie: thus, at Amsterdam, they formerly, before the barbarous French invasion, gave 103 or 104 florins for every 100 florins in bank. At Venice, the agio was fixed at 20 per cent.

The agio of the bank of Hamburg is about 14 per cent. which is the supposed difference between the good standard money of the state, and the clipped, worn, and diminished currency poured into it from neighbouring states.

AGIO is also sometimes used for the profit arising from the discount of a note, bill, &c.

AGIO *of assurance*, the same with what we call policy of assurance.

AGIOSYMANDRUM, in the Greek church, subject to the Turks, a wooden machine, used instead of bells, the use of these being prohibited.

AGISTMENT, AGISTAGE, or AGISTATION, in law, the taking in other people's cattle to graze, at so much per week.

The term is peculiarly used for the taking in of cattle to be fed in the king's forests, as well as for the profits thence arising.

AGISTMENT is also used for a tax, burden, or charge, levied for repairing the sea banks in different parts of England.

AGISTMENT *tithe*, is a small tithe paid to the rector or vicar for pasturage of cattle, horses, or sheep. It is, however, understood to be payable only for dry or barren cattle, and not for cattle that are nourished for the plough or pail, because the parson has tithe for them in other kind. It is paid by the occupier of the ground, and not by the person who may happen to put his cattle there to graze at a certain hire per head. It is commonly estimated at 2*s.* in the pound, according to the value of the land. See Burn's Eccl. Law, tit. *Tithes*.

AGISTOR, or AGISTATOR, an officer belonging to forests, who had the care of the cattle taken in to be grazed, and levied the monies due on that account.

AGMEN, in the Roman art of war, denoted an army, or rather a part of it, in march: thus we read of the *primum agmen*, or van guard; *medium agmen*, or main body; and the *postremum agmen*, or rear guard. We also meet with the *agmen pilatum*, which was a part of the army, drawn up in form of an oblong parallelogram, and answering to what the moderns call column. The *agmen quadratum*, however, or square form, was that mostly practised in the Roman armies.

AGNOETÆ, a sect of heretics, so called on account of their maintaining that Christ was ignorant of many things, and particularly of the day of judgment: an opinion which they built upon the text, Mark xiii. 32.

AGNOMEN, in Roman antiquity, a kind of fourth or honorary name given to a person on account of some extraordinary action, virtue, or other accomplishment. Thus the agnomen Africanus was bestowed upon Publius Cornelius Scipio, on account of his great achievements in Africa. In cases of adoption, it was usual to retain their former cognomen, or family name, by way of agnomen: thus Marcus Junius Brutus, being adopted by Quintus Servilius Cæpio, called himself Quintus Servilius Cæpio Brutus.

AGNUS *dei*, in the church of Rome, a cake of wax, stamped with the figure of a lamb supporting a cross. These being consecrated by the pope with great solemnity, and distributed among the people, are supposed to have great efficacy: as to preserve those who carry them worthily, and with faith, from all manner of accidents; to expel evils spirits, &c. It is also a popular name for that part of the mass, where the priest strikes his breast thrice, and says the prayer beginning with the words *agnus dei*.

AGONALIA, festivals celebrated in honour of Janus, or of the god Agonius, whom the Romans invoked before undertaking any affair of importance. They seem to have been kept three times in the year, *viz.* on the 5th of the ides of January, on the 12th of the calends of June, and on the 3d of the ides of December.

AGONISTICI, a name given by Donatus to such of his disciples as he sent to fairs, markets, and other public places, to preach and propagate his doctrine.

AGONIUM, in Roman antiquity, was used for the day on which the *rex sacrorum* sacrificed a victim, as well as for the place where the games were celebrated, otherwise called agon.

AGONOTHETA, or AGONOTHETES, in Grecian antiquity, was the president or superintendant of the sacred games; who not only defrayed the expenses attending them, but inspected the manners and discipline of the athletæ, and adjudged the prizes to the victors. At first there was only one agonotheta in the Olympic games; but several colleagues were afterward joined with him, three of whom had the direction of the horse races, three others of the pentathlon, and the rest of the other exercises.

AGONYCLITÆ, or AGONYCLITES, a sect of Christians, in the seventh century, who prayed always standing, as thinking it unlawful to kneel.

AGORANOMUS, a magistrate of Athens who had the regulation of weights and measures, of the prices of provisions, &c. The agoranomus answered in part to the ædile of the Romans.

AGOSTUS signifies the part of the arm from the fingers to the elbow: also the palm or hollow of the hand.

AGRARIAN *stations*, *agrariæ stationes*, in the Roman art of war, were a kind of advanced guards, posted in the fields.

AGRARIAN *laws*, among the same people, were those relating to the division and distribution of lands; of which there were a great number: but that called the *agrarian law* by way of eminence, was published by Spurius Cassius, about the year of Rome 268, for dividing the conquered lands equally among all the citizens, and limiting the number of acres which each citizen might enjoy.

AGREEMENT, in law, signifies the consent of persons to any thing done, or to be done.

There are three kinds of agreement; first, an agreement already executed at the beginning; as when money is paid, or other satisfaction made for the thing agreed to. Secondly, an agreement after an act done by another, to which a person agrees: this is also executed. Thirdly, an agreement executory, or to be executed in time to come.

An agreement is generally made preparatory to some more formal instrument of conveyance. On breach of an agreement there is a remedy either at common law, or in a court of equity. But when the matter is merely in damages, there the remedy is at law; because the damages cannot be ascertained by the conscience of the chancellor, but by the verdict of a jury. All agreements to be valid ought to be on a stamp, or at least duly stamped at the stamp office within the time limited by law, *viz. twenty-one* days after the date of the agreement.

AGRICULTURE. See GARDENING and HUSBANDRY.

AGRIMONIA, a genus of the dodecandria digynia class and order of plants, with rosaceous flowers, the cup of which at length becomes an oblong echinated fruit, containing one or two oblong seeds. The essential character is, calyx five cleft, fenced with one another; petals five; seeds two, at the bottom of the calyx.

There are five species; two, the A. rupatoria, or common A. and the A. odorata, natives of Great Britain. The leaves of the common agrimony make a very pleasant tea, said to be good in the jaundice, in cachectic cases, and in obstructions of the liver and spleen. The country people also formerly used it, by way of cataplasm, in contusions and fresh wounds.

AGRIPPA, a denomination given by ancient as well as modern physicians, to children born with the feet foremost. See MIDWIFERY.

AGROSTEMA, a genus of decandrious plants, according to Linnæus; but comprehended among the lychnises by Tournefort.

The class and order is decandria pentagynia. The corolla is wheel shaped; and the essential character is, calyx one leaved, coriaceous; petals five, clawed; border obtuse, undivided; capsule one celled.

There are four species, all well known as highly ornamental to our fields and gardens. The A. githago, or corn cockle, though a troublesome weed to the farmer, is beautiful to the eye. It is an annual plant, and flowers in June and July. The agrostema coronaria, or rose campion, has long been an inhabitant of our gardens, and the double variety is particularly handsome. It is biennial, and sometimes perennial, though apt, in the gardener's phrase, to *fog* off after it has flowered. The A. flos Jovis is more rare, but is an elegant perennial. The A. cœli rosa is an annual, very delicate and beautiful.

AGROSTIS, a genus of triandrious plants, called in English bent grass. It is of the class and order triandria digynia. The essential character is, calyx bivalve, one flowered, a little less than the corolla; stigmas longitudinally shaped.

There are not less than 35 species of this grass; most of them are foreign, and some only annual. About eight species are enumerated as natives of Britain.

AGROSTOGRAPHIA signifies the history or description of grasses. Such is that of Scheuzer, containing an accurate description of several hundred species of grass.

AGROUND, expresses the situation of a ship, the bottom of which rests on the ground.

AGRYPNIA, denotes much the same with watchfulness, or an inaptitude to sleep; which is a very troublesome symptom of feverish, and other disorders.

AGRYPNIA, in the Greek church, the vigil of any of the greater festivals.

AGUE, a general name for all intermittent fevers, which, according to the different times of the return of the feverish paroxysm, or fit, are denominated quotidian, tertian, or quartan agues. See MEDICINE.

AGURAH, in Jewish antiquity, the name of a silver coin, otherwise called gerah and keshitah.

AGUSADURA, AGUSAGE, in our old customs, a certain fee paid by vassals to their lord, for the sharpening of their plough tackle.

AGYNEIA, a genus of the monoecia monadelphia class and order. The essential character is, calyx six leaved; corolla none. In the male flowers the anthers are three, growing to the rudiments of the style. In the female the germ is perforated at top, without style or stigma.

The genus comprehends two shrubs, natives of China, but of little note.

AGYNIANI, a sect of heretics who condemned all carnal commerce with women.

AHEAD, refers to any object that lies immediately before a ship, or toward that point of the compass to which her prow is directed, used in opposition to *astern*.

AHULL, denotes the situation of a ship, when all her sails are furled, on account of the violence of a storm, and when, having lashed her helm to the lee side, she lies nearly with her side to the wind and sea, her head being somewhat inclined to the direction of the wind.

AID, in law, denotes a petition made in court to call in help from another person, who has interest in land, or other thing contested. This is called *aid prier*, which not only strengthens the party that prays for the aid, but gives the other person an opportunity of avoiding the prejudice that might otherwise accrue to his own right. Thus, a tenant for life may pray aid of the person in reversion; and a city or borough that holds a free farm of the king, if any thing is demanded of them, may pray for aid of the king.

AID, *auxilium*, in ancient customs, a subsidy paid by vassals to their lord on certain occasions.

Such were the aid of relief, paid upon the death of the lord mesne, to his heir; the *aid cheval*, or capital aid, due to the chief lord on several occasions; as to make his eldest son a knight, to make up a portion for marrying his daughter, and so in other cases.

AIGHENDALE, the name of a liquid measure used in Lancashire, containing seven quarts.

AIGUILLE, an instrument used by engineers to pierce a rock for the lodgment of powder; as in a mine, or to mine a rock, so as to excavate and make roads.

AIGUISCE', AIGUISSE', or EGUISCE', in heraldry, denotes a cross with its four ends sharpened, but so as to terminate in obtuse angles. It differs from the cross fitchee, inasmuch as the latter goes tapering by degrees to a point, and the former only at the ends.

AILANTHUS denotes, in Amboyna, the tree of heaven, so called on account of its lofty growth; a genus of tree, the class and order of which are not ascertained: some accounting it polygamia monoecia, and some dioecia decandria. It has male, female, and hermaphrodite flowers. It is a native of China, but grows very fast in our climate, and is recommended for ornamental plantations. If the bark is wounded, a resinous juice flows out, which hardens in a few days. The wood is hard, heavy, glossy, resembling satin. We know of only one species.

AILE, or AIEL, in law, a writ which lies where a person's grandfather, or great grandfather, being seized of lands, &c. in fee simple the day that he died, the stranger abates or enters the same day, and dispossesses the heir of his inheritance.

AIM FRONTLET, a piece of wood, hollowed out to fit the muzzle of a gun, to make it of an equal height with the breech, formerly made use of by the gunners to level and direct their pieces.

AIR. The most important discoveries of modern philosophy are those which relate to the composition of fluids, and of the elastic or *aerial* fluids in particular. The restricted form of a dictionary, which is confined to the alphabetical arrangement, renders the development of science, so as to meet and satisfy the ideas of the young student, in some measure difficult. We shall depart from it in this instance, in order to render clear, if possible, the present most important article, which may serve in some measure as a key to the most valuable discoveries of modern science.

The air, even of the atmosphere, was formerly accounted an elementary principle. It never entered into the minds of philosophers that it was of a compound nature. It is indeed somewhat extraordinary that they never were led to investigate the causes of *fluidity* itself, or to inquire what were the circumstances which constituted a fluid substance.

Previous to the grand discovery of Dr. Black, Boerhaave, Hales, and some other philosophers, had suspected that the presence of heat, or the elementary matter of fire, was the efficient cause of fluidity. The melting of tallow, wax, and metals, by the application of heat, and the condensation of water into ice, by the withdrawing of it, had led them insensibly to this conclusion; which was confirmed on finding that mercury, which has so strong an attraction or affinity for the matter of heat or fire, that it remains fluid in the usual temperature of our atmosphere, became a solid metallic mass, ductile, and possessing all the qualities of a metal, in a certain degree of cold, beyond what is common in these climates.

The indefatigable Dr. Black, on investigating fully the nature of heat, or elementary fire, found that the first effect of its admission in a larger quantity than usual to solid bodies was to *expand* them; that the next effect was to reduce them to a *fluid* state; and that the last effect was to present them in a state of an *elastic* or aerial fluid. Thus, water, in what may be called its natural state, is *ice;* by the application of a higher degree of heat, above 32 degrees of our thermometer, it becomes fluid: and by increasing the heat to above 212 degrees, it is converted into vapour, which is an *elastic* or compressible fluid. Hence it was concluded, that *heat*, elementary fire, or, as it is called in modern chymistry, *caloric*, is the only permanent fluid in nature, and the cause of all fluidity in all other substances whatever. It was found also, that certain substances had a stronger attraction for caloric than others; hence it was accounted for why certain matters continued in a fluid state, and some even in that of elastic fluids, in the ordinary state of our atmosphere. See CALORIC and FLUIDITY.

Some of these aeriform fluids are found to retain their elasticity only in a very high temperature. Such is the vapour from common water; such as forms smoke, clouds, &c. and such are the vapours which arise in distillation, and which are condensed as soon as the superfluous caloric, or heat, is withdrawn; See DISTILLATION; while others retain their aerial form in all the varieties of our atmosphere. Hence arose a distinction between *elastic fluids* and *permanently elastic fluids*. These latter, for a reason that will be presently assigned, were called *gases*. Some of these will be found to be *simple*, that is, when caloric is united with some simple elementary substance; others will be found of a compound nature, when two elementary substances are held suspended in a mixed state by the matter of caloric; and such is our common atmospheric air, which consists of two elementary substances; *oxygen* in the proportion of about one fourth, and *azote*

about three fourths, suspended in a mass of *caloric*. See Oxygen, Azote, &c.

Hence it is evident that the aeriform fluids differ from each other, according to the nature of the elementary principles which form their respective bases. This was, however, a matter which did not strike the early chymists. Though they perceived that those fluids which were occasionally raised in their processes, were permanently elastic, and different in their nature from common air, they did not inquire into their different properties, contenting themselves with giving them a name which meant nothing, denominating them, in general, *spiritus sylvestris*.

Van Helmont distinguished them by the name of *gas*, which he defined to be a spirit, or incoercible vapour, as the word *gas*, or rather *ghoast*, in the Dutch language, signifies. He supposes the *gas* to have been retained by the substances from which it is extracted, in a fixed or concrete form. He asserts, that sixty-two pounds of charcoal contain sixty-one of gas, and only one of earth, and attributes the fatal effects which workmen experience occasionally in mines to the emancipation of this spirit. On the same principle he accounts for the eructations from the stomach and bowels, and for the floating of drowned bodies; and he concludes by determining, that this gas is a fluid of a nature quite different from that of our common air.

The existence of two different kinds of vapour or elastic fluids, had been previously observed in mines and coal works: the one was observed to affect animals with a sense of suffocation, and to extinguish life, and it therefore obtained the name of the *choke damp;* the other, from the dangerous property of catching fire when a candle or any ignited body was brought in contact with it, was termed the *fire damp*.

A specimen of the fire damp, or inflammable air, was collected from a coal mine of sir James Lowther, in Cumberland, and brought up in bladders to be exhibited to the Royal Society at London, in the year 1733; and in the year 1736 Mr. John Maud procured, from the solution of iron in oil of vitriol, a quantity of the very same species of inflammable air, and demonstrated that the same might be procured from most of the metals in certain circumstances.

The experiments of Van Helmont were greatly improved upon by the sagacious Boyle. He changed the name of gas to that of *artificial air;* he demonstrated, that this *artificial air* was not always the same; for instance, that the air produced by fermentation is essentially different from that which is formed from the explosion of gunpowder. He was the first who perceived that the volume of air was diminished by the combustion of certain substances.

This last observation of Mr. Boyle seems particularly to have attracted the attention of Dr. Hales, and he invented instruments for determining the quantities both of the air, which was on some occasions produced, and on other occasions absorbed, by different substances. These experiments deserve the attention of every philosopher, and for accuracy or ingenuity have never been exceeded.

Among other circumstances which were particularly remarked by Dr. Hales, was the great quantity of air contained in the acidulated mineral waters, and to this air he suspected they were indebted for their sparkling and brightness, and some other of their peculiar qualities. In observing the absorption of air by bodies in combustion, he saw that this absorption had its limits: he remarked also, in some cases, the alternate production and absorption of air, as for instance in respect to the air which he produced from the burning of nitre, which air, he observed, was very soon diminished in bulk, though he did not perceive that the absorption was owing to the water, which he always used in his experiments. The production of an air capable of inflammation from the distillation of certain substances did not escape his observation; and he has advanced, that the augmentation of weight in the metallic calces was in some degree owing to the air which they imbibed. That the phosphorus of Homberg diminishes the air in which it is burned; that nitre cannot explode in vacuo; and that air is in general necessary to the crystallization of salts; are among the facts, which are noticed by this philosopher.

From the uncertainty, however, of Dr. Hales and his predecessors, with regard to several material circumstances, of which they appear to have had some casual glimpses, and from their total ignorance of others, the doctrine of the aerial fluids was but in a state of infancy, till the decisive experiments of Dr. Black, Mr. Cavendish, and Dr. Priestley, furnished us with a new system in this important department of natural history.

The first of these philosophers observed, that lime and magnesia, in their mild state, consist of an union of a certain aerial fluid with the earthy base; that this aerial matter is actually extracted by the operation of burning, which reduces ordinary calcareous earth to the state of quick lime; and that it is afterward reabsorbed by the quick lime when exposed to the air. On this principle he was able, not only to account for the loss of weight by the burning of limestone, but to estimate to the greatest nicety the additional weight which it could acquire from the atmosphere. He extracted the gas, to which he gave the name of fixed or fixable air, also by another process, namely, by dissolving the calcareous earth in acids; he found that the causticity of lime depended upon its violently attracting from vegetable and animal matter a portion of that air of which it had been deprived, and that upon this principle he was enabled to render caustic the alkaline salts.

To Mr. Cavendish the second place in the order of this history belongs. He pursued the experiments of Dr. Black, and ascertained the quantity of fixed air which could be retained by the fixed and volatile alkalies. He accounted for the nature of acidulated waters, by the fixable air which they contained. He procured a species of inflammable air from solutions of iron and zinc in vitriolic acid; and he was the first who remarked, that a solution of copper in spirit of salt, instead of yielding inflammable air, like that of iron or zinc, afforded a particular species of air, which lost its elasticity by coming in contact with water.

Dr. Priestley commenced his philosophical career by some experiments upon fixable air: and the first of his communications to the public related to the impregnating of water with this air, by means of chalk and oil of vitriol, a method first hinted by Dr. Brownrigg of Whitehaven, and now commonly practised in the imitations of the acidulated mineral waters. The doctor tried the power of

fixable air upon animal and vegetable life, and found it fatal to both.

The indefatigable mind of Dr. Priestley was not, however, to be satisfied with the investigation of a single object. He next turned his attention to the nature of atmospheric air. He observed, after Dr. Hales, its diminution by different processes, as by combustion, &c. but differs as to the cause. Dr. Hales supposed the specific gravity of the air to be increased; but Dr. Priestley judged, that the denser part of the air is precipitated, and that the remainder is actually made lighter. The discovery that the atmospheric air is purified by vegetation is also Dr. Priestley's.

On pursuing the experiments of Mr. Cavendish on inflammable air, the doctor found that it was not only producible from iron and zinc, but from every inflammable substance whatever.

Dr. Priestley discovered the cause that air, which has been respired, is fatal to animal life, to be, that it becomes impregnated with something stimulating to the lungs, for they are affected in the same manner as when exposed to any other kind of noxious air.

But his most important discovery was, that the nitrous air which he procured from the solution of metals in the nitrous acid, had the property of destroying the purest part of the common air. On pursuing his experiments Dr. Priestley found, on extracting airs from different substances, that the air produced from calcined mercury, was of a purer nature, and more favourable to animal life and combustion, than common atmospheric air: it was, in truth, the same with the pure part of the air which was destroyed by the nitrous gas, as well as by breathing and combustion. He therefore denominated it PURE OR VITAL AIR, and this was afterward found to be what is now called OXYGEN AIR or GAS, the basis of which is oxygen, already noticed under the article ACID.

Dr. Priestley continued his experiments on inflammable air, and found that all the metals which yield it when dissolved in acids, yielded it by means of heat alone; his mode of extracting it was by subjecting the filings of the different metals in vacuo to the action of a burning glass.

The next remarkable, and perhaps the most important discovery, was that of Mr. Cavendish, which has explained to us the nature and composition of water. Mr. Cavendish was led to this great discovery by an experiment of Mr. Warltire, related by Dr. Priestley, in which it was found, that on inflaming a mixture of common and inflammable air by the electric spark, a loss of weight always ensued, and that the inside of the vessel in which it was fired became always moist or dewy, though ever so carefully dried before. On repeating the experiment, Mr. Cavendish did not perceive the diminution of weight which Mr. Warltire supposed to take place, but the latter effect was completely exemplified. In prosecuting the experiment, it appeared that it was only the pure or empyreal part, that is, about one fourth, of the common air which was consumed, and the water produced was perfectly tasteless and pure; on mixing vital with inflammable air in a due proportion, and passing through them an electric spark, the whole portion lost its elasticity, and was condensed into water.

Mr. Cavendish pursued his experiments with remarkable success, to ascertain the constituent principles of what was then called phlogisticated air, or that which constitutes the impure and unrespirable portion of the atmospheric air; and by passing the electric spark through common air, and through a certain mixture of vital and phlogisticated airs, he was able totally to condense the latter, and to ascertain its constituent principle to be the same with that of nitrous acid, with, as he then thought, a small portion of inflammable matter. In this latter opinion, however, he has since been corrected by Lavoisier, and other modern chymists, who have proved that azotic, or phlogisticated air, as it is called by the English chymists, is no other than the basis of the nitrous acid.

In Mr. Cavendish's experiment, as he probably used air which had been rendered impure by combustion, some small portion of charcoal, or other inflammable matter, might be contained in the air.

Some gases exist in nature without the aid of art, and may be collected; others are only producible by artificial means. The principal airs, or gases, noticed in modern philosophy are,

Oxygen gas or air.	Phosphorated hydrogen gas.
Nitrogen gas or air.	Nitrous gas or air.
Hydrogen gas or air.	Sulphureous acid gas.
Ammoniacal gas or air.	Gaseous oxyd of azote.
Carbonic acid gas.	Muriatic acid gas.
Carbonated hydrogen gas.	Oxygenated muriatic acid gas.
Sulphurated hydrogen gas.	Fluoric acid gas.

AIR *vital*, or *Oxygen gas*, formerly termed also dephlogisticated and empyreal air: is a substance destitute both of taste and smell, but possessing in an eminent degree the power of increasing and supporting animal life and combustion. It is heavier at the same time than atmospheric air, in the proportion of 103 to 100, and the latter maintains life only in consequence of the quantity of this fluid it contains. This proportion is rated an 27 in 100.

This air changes the colour of animal and vegetable substances. It is a composition of oxygen and caloric. Combustion by it is rendered amazingly intense; and its powers, when urged by the blow pipe, far exceed the powers of any burning lens.

A lighted wax taper, fixed to an iron wire, and let down into a vessel of this gas, burns with an inconceivable brilliancy. If the taper is blown out, and let down into a vessel of the gas, while the snuff remains red hot, it instantly rekindles. A red hot piece of charcoal immersed in this gas, throws out beautiful sparks. In this gas thin iron wire will burn with beautiful effect. During every combustion in oxygen gas, the gas suffers a material diminution; and all bodies by combustion in it acquire an addition to their weight.

Oxygen, or the basis of oxygen gas, is naturally or artificially combined with a great variety of substances. From some of these it may be detached by the simple application of heat, since it has a remarkable attraction for caloric, or the matter of fire, with which when it unites, it becomes expanded, and assumes the form of gas or air.

The substances from which it may be most easily extracted, by means of heat, are red lead, calcined mercury, nitre, and manganese. Dr. Priestley exposed a quantity of red lead in the focus of a burning glass twelve inches in diameter. A quantity of fixed air, or carbonic acid gas, as it is now called, was always produced at first; but after that was separated, the remainder was found to support flame, and to sustain animal life, much more vigorously than common air, and to have all the characters of dephlogisticated air, or oxygen gas.

By various succeeding experiments of Dr. Priestley and others, it however appears, that dephlogisticated or oxygen air, may be obtained not only by means of heat, but also by the action of the vitriolic and nitrous acids upon a number of mineral and metallic substances.

This kind of air may also be obtained by the same process, from the native oxyd, or calx of manganese, or from minium or red lead, which, it is well known, is an oxyd of lead, or lead united with oxygen.

The better to understand these effects, it must be observed, that this fluid is not found in these substances in an entire state; they only contain the basis of it, which is the oxygen; for metals neither calcine nor burn, but in consequence of their combination with oxygen, which by that means becomes solid, and joins its weight with theirs. This oxygen is then expelled by the application of heat or caloric, which, combining with it, causes it to pass into the state of an elastic fluid; during this process, the metal, losing the oxygen which had reduced it to the state of an oxyd or calx, assumes its metallic properties, and loses the weight which it had acquired in becoming oxidated.

There is, however, a method by which oxygen gas may be obtained with less heat and greater facility, and it is as follows: put some red lead into a bottle, together with some good strong oil of vitriol, but without any water. Let the red lead fill about a quarter of the bottle, and the vitriolic acid be about the same quantity, or very little less; then apply a bent tube to the bottle, by inserting it through a cork, and having inverted another bottle filled with water in a basin about half filled also with water, direct the other end of the crooked tube into the bottle inverted in the water. In this stage of the process we must observe, that without heat, this mixture of red lead and vitriolic acid will not afford any oxygen air, or a very inconsiderable quantity; it is necessary, therefore, to apply the flame of a candle or wax taper to the bottle containing the ingredients, while the crooked tube opens a communication between this bottle and that inverted in the water. In this manner the red lead will yield a quantity of elastic fluid, which will pass through the crooked tube into the inverted bottle, and as the quantity of oxygen air increases in the inverted bottle, the water in it will be seen to subside; this air will not be all pure, because a considerable quantity of fixed air enters with it. In order to separate the fixed from the pure air, the inverted bottle, when filled with the compound of both, must be agitated in a basin of lime water, by which means the lime water will absorb the whole quantity of fixed air, and leave the dephlogisticated air or oxygen gas by itself.

Oxygen gas may also be obtained in considerable quantities from the decomposition of water, especially from pump water, which, when exposed to the sun, emits air slowly; but after it has remained so for a considerable time, a green matter adheres to the bottom and sides of the glass vessel in which it remained; afterward it emits pure oxygen air in great quantities, and continues to do so for a long time after the green matter has exhibited symptoms of decay by turning yellow.

Dr. Ingenhousz rightly supposed this green matter to belong to the vegetable kingdom, and procured pure air by putting the leaves of plants into water, and exposing them to the sun. He observes that of land vegetables the fittest for this purpose are the poisonous plants, such as hyoscyamus, lauro cerasus, nightshade, &c. But he extracted the purest air from some aquatic vegetables, and from turpentine trees, but especially from the green matter he collected from a stone trough, which had been kept filled with water from a spring near the high road.

While Dr. Priestley was engaged in a series of experiments to enable him to purify contaminated air, he discovered that vegetables answered this purpose most effectually. The experiment by which he illustrates his assertion was this: having rendered a quantity of air very noxious, by mice breathing and dying in it, he divided it into two receivers inverted in water, introducing a sprig of mint into one of them, and keeping the other receiver with the contaminated air in it alone. He found, about eight or nine days after, the air of the receiver, into which he had introduced the sprig of mint, had become respirable; for a mouse lived very well in this, but died immediately upon being introduced into the other receiver, containing the contaminated air alone.

It has since been observed, that several animal substances, as well as vegetables, have a power of separating dephlogisticated air, or oxygen gas, from water, when exposed to the action of the sun for a considerable time.

The ingenious count Rumford observed, that raw silk has a remarkable power of producing pure air. He found, that by introducing thirty grains of this substance, first washed in water, into a thin glass globe four inches and a half in diameter, having a cylindrical neck three fourths of an inch wide and twelve inches long, inverting the globe into a jar filled with the same kind of water, and exposing it to the action of the sun in the window, in less than ten minutes the silk became covered with an infinite number of air bubbles, gradually increasing in size, till at the end of two hours the silk was buoyed up, by their means, to the top of the water. They separated themselves by degrees, and formed a collection of air in the upper part of the globe, which, when examined by the established test, appeared to be very pure. In three days he collected three and three fourths of a cubic inch of pure air, into which a wax taper being introduced, that had just before been blown out, the wick only remaining red, it instantly took fire, and burned with a bright and enlarged flame. The water in the globe had acquired the smell of raw silk, it lost something of its transparency, and assumed a faint greenish cast.

It has been observed, that when this experiment was made in the dark, only a few inconsiderable bubbles were formed, which remained attached to the silk; nor was it otherwise when the glass globe was removed into a German stove. In the latter case, indeed, some single bubbles

had detached themselves from the silk, and ascended to the top, but the air was in too small a quantity to be either measured or proved.

In these experiments, the oxygen or pure air was extracted by an actual decomposition of a part of the water, by means of a capillary attraction, aided by the solar influence; and in effect the same philosopher was enabled to extract it, though in a smaller quantity, by means of a number of very minute glass tubes immersed in water, and exposed to the sun.

The reason that pure air is the most essential of all the fluids to the support of life is, probably, because a great quantity of heat is necessary for this purpose, and because this fluid contains it in great quantity, and parts with it very freely when it meets with any substance with which it has an affinity. But as its basis, oxygen, combines itself very easily with the basis of coal which is found in the blood and lungs, and during this combination, loses part of its caloric, or heat, which goes to the support of life, the remainder of the caloric and oxygen, combined with the coal, form the acid carbonic gas or fixable air, which is always found to exist in a larger quantity in air which has been respired, than in atmospherical air which has not been subservient to that function. Of this a very easy experiment affords sufficient proof; it is founded on the property which the carbonic gas has of rendering lime water turbid. A crooked tube open at both ends is partly filled with lime water; a person applies his mouth to one end of the tube, and inspires, by drawing the air through the lime water contained in it. By this the transparency of the lime water is not affected; but it becomes turbid as soon as the person expires, which is owing to the carbonic acid formed in the lungs. It is therefore the great attraction which exists between the matter of coal and the basis of pure air which renders this fluid so proper for breathing. The pure air which we breathe performs two functions equally necessary to our preservation; it carries off from the blood that matter of coal, the superabundance of which would be pernicious, and the heat which this combination deposites in the lungs repairs the continual loss of heat which we experience from surrounding bodies. According to Dr. Priestley, and others, the basis of oxygen gas is also absorbed by the blood.

Since, therefore, a great quantity of heat is disengaged from pure air in respiration, it follows, that this fluid must be very pernicious to animals who breathe this air alone for a considerable time; which is consonant with the observations of physicians, who have attempted to cure phthisics by the respiration of vital air.

The basis of this empyreal or pure air, or oxygen gas, as the French chymists term it, is one of the constituent parts of water. It has been mentioned, that it is also the matter which gives the acid character to the acids; sulphur, for instance, is a very innoxious, insipid body, till by burning, that is by absorbing oxygen, it becomes vitriolic acid. Whether the basis of this empyreal air is a simple or compound substance, we are unable to determine; in the present state, however, of philosophical knowledge, we are justified in considering it as a simple elementary body, for it has never yet been decomposed.

Air *Azotic*, or *Nitrogen gas*, named also mephitis, is a substance unlike the former, being incapable of supporting animal life. It extinguishes flame, and is only characterized by possessing none of the distinguishing qualities of the other known airs. It is lighter than common air, in the proportion of 985 to 1000. It may be considered indeed as the residue of common air, when vitiated by combustion. It is easily disengaged from animal matters, by a slight increase of temperature; but different parts of animals afford different proportions of it, and the concrescible fibrous matter the most. The portion of it they in general afford is proportioned to their quantity of volatile alkali.

Azotic or nitrogen gas may be procured by mixing equal weights of iron filings and sulphur into a paste with water, and placing the mixture in a proper vessel over water. Then invert over it a jar full of common air, and allow it to stand exposed to the mixture a day or two. The air contained in the jar will gradually diminish, as will appear from the ascent of the water within the jar, till at last only about three fourths of its original bulk remain.

This gas is not absorbed by water: it immediately extinguishes a lighted candle, and other burning substances: it is fatal to animals confined in it: plants, however, live and flourish in it: by it delicate blue colours are slightly reddened; and when mixed with oxygen gas, in the proportion of three or four parts of azotic gas to one of oxygen, it composes a mixture resembling atmospheric air. Its basis is azote, an elementary substance, which is also the basis of nitrous acid or aquafortis. Its combination with oxygen gives it the acid character. In this state it is combined with that substance. In the state of atmospheric air it is only mixed.

Air, *Inflammable*, or *Hydrogen gas*. This air, named also fire damp, is peculiarly distinguished by its great levity and inflammability. It is the lightest substance whose weight we are able to estimate. When pure, it is thirteen times lighter than atmospheric air, and it immediately explodes on mixture with oxygen. It is formed by the union of hydrogen and caloric. Its lightness is particularly evinced by its use in balloons. Plants grow in this fluid without impairing its inflammability. Water imbibes about one thirteenth part of it; and when again expelled, it is as inflammable as ever. By this addition both its bulk and specific gravity are increased; for it occupies one eighth more space by its combination, and its weight is increased, so as to be only one tenth lighter than common air.

Hydrogen gas is thus procured: let sulphuric acid, diluted with five or six times its weight of water, be poured on iron filings in a glass bottle or small retort. An effervescence will ensue, and the gas which escapes is inflammable air or dydrogen gas. This effect is produced by the decomposition of the watery parts of the acid; the oxygen is absorbed by the metal, and with the sulphur forms a solid saline mass; martial vitriol, or copperas. The hydrogen which enters into the composition of the water is disengaged in the form of hydrogen gas.

According to M. Lavoisier, water is composed of eighty-five parts of oxygen and fifteen parts of hydrogen. This philosopher has instructed us in the following method of obtaining this gas by heat only.

Let water pass drop by drop through the barrel of a gun, while it remains red hot amidst burning coals; let a

crooked tube be placed at the end of this iron, and bent, so that it may be passed into a glass vessel full of water inverted in the pneumatic apparatus. There will then pass into the glass vessel an aeriform fluid, which is inflammable air or hydrogen gas. In this process the water suffers a decomposition, and while the hydrogen passes into the glass receiver, the oxygen unites with the substance of the gun barrel, and oxydates or rusts its internal surface.

The electric spark also, taken in any species of oil, produces hydrogen or inflammable air, this substance being a constituent part of all the oils. The same may be said of æther, and alcohol or spirit of wine, which contain a great proportion of hydrogen.

Mr. Cavallo informs us, that he has procured this kind of air from the ponds about London, in the following manner: fill a wide mouthed bottle with pond water, and keep it inverted in it; then with a stick stir the mud at the bottom of the pond just under the inverted bottle, so as to permit the bubbles of air which rise to be received in the inverted bottle; and this air will be found to be inflammable.

The ignes fatui are supposed to proceed from the inflammable air which abounds in marshy grounds, and to be set on fire by electric sparks.

The most remarkable properties of this gas are, 1st, its great inflammability, which arises from its propensity to unite with oxygen and form water. 2dly, Its extraordinary levity, as already noticed. 3dly, Metals are very easily revived or reduced from a calx or oxyd to the metallic state when heated in a receiver filled with this air. This also arises from its attraction for oxygen, which in this case is expelled from the calx; and, uniting with the hydrogen in the receiver to form water, leaves the metal pure, and in its natural state. 4thly, Plants vegetate in this fluid without impairing its inflammability. 5thly, Water will imbibe about 1-13th of its bulk of this gas.

6thly, A very clear sound resembling that of the æolian harp, is produced by placing a tube of glass or earthen ware over this gas while burning. The sound may be varied at pleasure, by raising or lowering the tube, or by using those of different dimensions. What renders this most extraordinary is peculiar to the burning of hydrogen gas. (*a*)

This gas remains permanent over water; it is inflammable. Fill a small jar or common phial with the gas, and holding it with its mouth downward, bring the gas into contact with the flame of a candle; the air will take fire, and burn silently with a bluish flame. In a strong phial mix equal parts of hydrogen gas and common air, and apply to the mouth a lighted candle, and it will burn with a sudden and loud explosion. One part of oxygen gas, and two or three of hydrogen gas, will give a report equal to that of a pistol.

Hydrogen gas has an unpleasant smell; it extinguishes burning bodies: it is fatal to animals; and is, as we have observed, considerably lighter than atmospherical air.

These then are the three simple or original gases, from which, variously modified, all the rest are produced; and the first of these productions is universally diffused, and of the first importance to life, constituting an essential part of what we constantly breathe, and by which we are surrounded, atmospheric air.

Air, *combined*, or *atmospheric gas*, is a mixture of two or three substances in the elastic state. By the powers of chymistry this fluid, when examined, is found to consist principally of oxygen air, azote, and carbonic acid in certain proportions. From the abundant production of inflammable air, or hydrogen gas, at the surface of the earth, in consequence of the corruption or decomposition of animal and vegetable matters, this fluid must also be generated; yet its extreme levity will naturally carry it to the higher regions, so that, though a part of the atmosphere, it is placed in a situation beyond the examination of chymists.

To a mixture then of oxygen and azotic air, with carbonic acid, the term atmospheric air is applied; and this mixture is in the proportion of 27 parts of oxygen air, 72 of azotic, and one of carbonic acid gas.

The proofs of this composition of atmospheric air were first offered by Mr. Scheele, who found, on its exposure to certain substances, that it suffered a diminution of volume, and that by this diminution it was rendered unfit for the support of life. This abstracted part, therefore, could not fail to be oxygen or vital air; and from this mixture of oxygen and azote, he naturally inferred that atmospheric air came to be formed. This he further confirmed by restoring oxygen to it, in consequence of which it regained all its properties of atmospheric air. On the same subject he was succeeded by Lavoisier, who, in addition to these facts, showed that the oxygen, or attracted part, was received by the substance producing the change, and could be often recovered again from it.

But though the composition of atmospheric air has been thus ascertained, something still remains wanting to complete it; and this is, the manner of combining by experiment its parts. Hence it is doubted whether its parts exist naturally in a state of chymical combination, or of mechanical mixture. That the latter takes place appears probable from the different proportion of oxygen which it is found to contain in the higher and lower regions, it being always greater toward the surface of the earth; and from the unlimited proportion in which these airs can be mixed, while the different matters present in the atmospheric regions may tend strongly to prevent their separation. At the same time, as a proof of its simple mixture, it is soluble in 30 times its weight of water.

From this knowledge of the composition of atmospheric air, an attempt has been made to ascertain its purity, or its relative capability of supporting animal life in different situations. This is effected by eudiometry, or measuring the exact quantity of oxygen the air contains.

To do this it requires to add to the air some body capable of combining with its oxygen, and from the diminished volume of air, the quantity of oxygen is inferred.

Different substances have been employed for this purpose, and each preferred by different chymists.

The first eudiometer was made in consequence of Dr. Priestley's discovery, that when nitrous gas is mixed with atmospheric air over water, the bulk of the mixture diminishes rapidly; in consequence of the combination of the gas with the oxygen of the common air, and the absorption of the nitric acid thus formed by the water.

When nitrous gas is added to nitrogen gas, no diminution takes place; but when it is mixed with oxygen gas in proper proportions, the absorption is complete. Hence

it is evident, that in all cases of a mixture of these two gases, the diminution will be in proportion to the quantity of the oxygen. Of course, it will indicate the proportion of oxygen in atmospheric air, and, by mixing it with different proportions of air, it will indicate the different quantities of oxygen which they contain, provided the component parts of air are susceptible of variation.

Dr. Priestley's method was, to mix together equal quantities of air and nitrous gas in a low jar, and then transfer the mixture into a narrow graduated glass tube, about three feet long, in order to measure the diminution of bulk. He expressed this diminution by the number of hundredth parts of nitrous gas and common air: and if the sum total was 200, or 2.00; suppose the residuum, when measured in the graduated tube, to amount to 104, or 1.04, and of course, that 96 parts of the whole had disappeared, he denoted the purity of the air thus tried by 104.

Atmospherical air is without taste, and for the most part without smell. It is invisible, transparent, necessary to the support of combustion, vegetation, and animal life, particularly respiration. It is absorbed in a certain quantity by water, and again expelled by boiling, or by the air pump removing pressure.

Air, *alkaline*, or *ammoniacal gas*. This air possesses a strong pungent smell, and is even capable of inflaming the skin of animals. Its lightness is next to that of inflammable air, and in specific gravity it falls short of atmospheric air, in the proportion of 600 to 1000, and it is incapable of supporting animal life, and also combustion, though the flame of a candle enlarges before it is extinguished by it. It is proved to be a compound of azote and hydrogen, 1000 parts of it containing 807 of azote, and 193 of hydrogen. This air has a strong attraction for water, and is rapidly absorbed by it. When dissolved with water it produces heat; and when dissolved with ice it produces cold.

Ammoniacal gas was first discovered by Dr. Priestley: it is no where found in a natural state, but must be produced by an artificial process. To obtain it, put into a retort a certain quantity of liquid ammonia, and heat the bottom of the retort, and having suffered some air to escape from the retort and the tube, the gas may be collected in vessels filled with mercury. This gas, which seems to be nothing but ammonia deprived of water, is perfectly absorbable by water, and the solution forms liquid ammonia, the same which is vulgarly called sal volatile and spirit of hartshorn. It is the lightest of all the saline gases, has a penetrating odour, and gives a strong tint of green to blue vegetable colours. It combines rapidly with carbonic, muriatic, and sulphureous acid gases, and forms neutral salts, throwing out a great deal of heat, which arises from the free state of the caloric that had been combined with these gases.

Ammoniacal gas suffocates animals, and extinguishes burning bodies; but it is so far inflammable, that it increases the flame of a taper before it extinguishes it.

Carbonic *acid gas* is the first elastic aeriform fluid, different from common air, that was known. We are indebted to Dr. Black, of Edinburgh, for a knowledge of some of its most remarkable properties. In the year 1755 he discovered the affinity between it and the alkalies; and Bergmann, in 1772, proved that it was an acid.

Carbonic acid gas cannot support flame, nor animal life: its taste is acid. Neither light nor caloric seem to produce any effect upon it, except that the latter dilates it. It is absorbed by water. These two fluids, after considerable agitation, at last unite, and form an acid fluid. The colder the water, and the greater the pressure applied, the more carbonic gas it will absorb. Water, so impregnated, sparkles upon agitation; it has an acidulous taste, and reddens tincture of litmus. Heat disengages the gas from the water. Carbonic acid gas precipitates lime from its solution in water. It is eagerly attracted by the alkalies. Its specific weight is to that of atmospheric air, as 1500 to 1000. It may be poured from one vessel into another.

Of all the bases of the gases, that of carbonic acid gas is diffused in the greatest abundance throughout nature. It is found in the state of gas, and also in combination with a great variety of bodies.

It may be easily obtained as follows: Put into a common retort a little marble, chalk, or limestone, and pour on it sulphuric acid, diluted with about six times its weight of water; an effervescence will ensue, and carbonic gas will be disengaged, which may be collected over mercury; but a mercurial apparatus is not absolutely necessary, since the gas may be collected over water, if it is to be used immediately.

Marble, limestone, and chalk, consist of this matter and lime. On presenting to it sulphuric acid, a decomposition takes place; the sulphuric acid having a greater affinity to the lime than the carbonic acid has. It therefore unites to it, and forms sulphate of lime, disengaging, at the same time, the carbonic acid in the state of gas.

Carbonic acid gas is often found in the lower parts of mines, caverns, tombs, and such other subterraneous places as contain materials for producing it: it is then called the *choke damp*. The grotto Del Cane, near Naples, has long been famous for the quantity of this gas produced there, which is so great, that it runs out at the opening like a stream of water. A dog, or any other animal, is immediately killed, if its nose is thrust into the lower part of the cavern. But the upper part of the cavern is quite free from the gas, as it does not rise high enough to mix with the atmospheric air.

Carbonic acid gas is likewise formed during fermentation. On account of its great weight, it occupies the empty space of the vessel in which the fermenting process is going on. It may, in this case, be collected by plunging a vessel into it.

Light carbonated hydrogen gas, is hydrogen gas holding in solution carbon or charcoal. There are several kinds of it obtained by different processes, which differ in their properties, and in the proportions of their constituent principles.

Light carbonated hydrogen gas has a disagreeable smell. It is neither absorbed nor altered by water. It is very inflammable, and burns with a denser and deeper coloured flame than pure hydrogen gas. Its specific gravity is greater than that of hydrogen gas, or of common air.

This gas is produced from animal, vegetable, and mineral substances. It is found very commonly in marshes and ditches, on the surface of putrid water, in burying

places, common sewers, and in those situations where putrid animal and vegetable matters are accumulated. It is also generated in the intestinal canal of living animals.

It may be plentifully obtained from most stagnated waters. To do this, fill a wide mouthed bottle with water, and keep it inverted with a funnel in its neck: then stir the mud with a stick at the bottom just under the funnel, so as to collect the bubbles of air which rise in various places: as soon as the bottle is filled with gas, it must be corked under water.

It may also be obtained during the distillation of animal and vegetable matters. Let shavings of wood or sawdust be put into a retort, and apply a gradual heat till the retort becomes red hot: a great quantity of gas will be disengaged, which may be collected over water. On examining this gas, it will be found to consist of carbonic acid gas and carbonated hydrogen gas. In order to obtain the latter in a pure state, the whole must be mixed with lime water, or with caustic alkali dissolved in water. The carbonic acid gas will be absorbed, and the carbonated hydrogen gas left behind.

Heavy carbonated hydrogen gas is not absorbed by water. It has an odour different from that of light carbonated hydrogen gas. It burns with a strong flame, similar to that of a resinous oil. When mixed with oxygenated muriatic acid gas, its bulk is diminished, and oil is formed. When the mixture of these two gases is exploded, a quantity of charcoal is immediately deposited in the form of fine soot. When burned with oxygen gas, or when passed through a red hot tube filled with any oxyd from which oxygen is procured, carbonic acid gas is formed.

This gas is obtained by decomposing spirit of wine, by sulphuric acid in a great heat. It is also obtained abundantly, when alcohol is passed through a red hot earthen tube. Sulphuric æther, mixed with sulphuric acid, and subjected to heat, also affords it.

Let four parts of sulphuric acid, and one of highly rectified ardent spirit, be mingled together gradually in a glass retort: heat will be disengaged, the mixture will become brown, and heavy carbonated hydrogen gas will be extricated. When heat is applied, the action is very violent, and the gas is procured very copiously, and may be received over water. The gas so obtained is mixed with a considerable quantity of sulphureous acid gas, from which it may be freed, by agitating it with lime water, or a solution of potash.

Sulphurated hydrogen gas has the properties of an acid; for when absorbed by water, its solution reddens vegetable blues. It combines also with alkalis, earths, and with several metallic oxyds. Sulphurated hydrogen gas has an extremely offensive odour, resembling that of putrid eggs. It kills animals, and extinguishes burning bodies. When mixed with oxygen gas, or atmospheric air, it is inflammable.

To obtain it, take dry sulphuret of potash, put it into a tubulated retort in a sand bath; or, supported over a lamp, direct the neck of the retort under the receiver placed in a pneumatic trough; then pour gradually upon the sulphuret diluted sulphuric acid: a violent effervescence will take place, and sulphurated hydrogen gas will be disengaged. When no more gas is produced, apply heat by degrees till it boils, and gas will again be procured abundantly.

The water employed for receiving it should be heated to about 80 or 90 degrees: at this temperature it dissolves little of the gas; whereas, if cold water is used, a vast quantity of it is absorbed.

Water impregnated with sulphurated hydrogen gas, slightly reddens blue vegetable colours.

It is this gas which gives to the mineral waters of Harrowgate and Aix-la-Chapelle their peculiar smell. Such waters may therefore be artificially imitated, by impregnating common water with this gas, and adding the other constituent parts to it.

This gas acts strongly on most metallic oxyds.

Dip a slip of paper into a solution of lead, and expose it to the action of sulphurated hydrogen gas; and the paper will instantly become blackened. Writing performed with this solution is invisible when dry, but becomes visible when immersed in a bottle filled with this gas.

In this instance, the hydrogen of the gas takes the oxygen from these bodies, and causes them to reapproach the metallic state; at the same time, the sulphur contained in the gas combines with the metal thus regenerated, and converts it into a sulphuret.

Phosphorated hydrogen gas consists of phosphorus dissolved in hydrogen gas.

It is the most combustible substance in nature. It is distinguished from all other gases by the property of taking fire immediately when brought in contact with atmospheric air. When mixed with oxygen gas, or with oxygenated muriatic acid gas, it burns with great violence. When bubbles of it are suffered to pass through water, they take fire in succession as they reach the surface of the fluid. It has an insupportable odour, similar to that of putrid fish.

To obtain it, take a small retort, put into it one part of phosphorus and ten of concentrated solution of potash; make the mixture boil, and receive the gas over mercury, or, if it is intended for immediate use, it may be collected over water. In this process a decomposition of the water takes place. Its oxygen unites to part of the phosphorus, forming phosphoric acid, which joins to the potash, and forms phosphate of potash. The hydrogen of the water dissolves another part of the phosphorus, and is converted into phosphorated hydrogen gas.

In preparing this gas the body of the retort should be filled as nearly as possible with the mixture, otherwise the first portion of gas which is produced inflames in the retort, a vacuum is formed, and the water is forced up into the retort, which endangers the bursting of it.

Phosphorated hydrogen gas is also formed by nature. The air which burns at the surface of certain springs, and forms what is called burning springs, and the *ignis fatuus*, jack o'lantern, which glides along burying grounds, consists of this gas.

If the bubbles of air which come from the retort are suffered to escape into the atmosphere, they will burst with a slight explosion, and produce flashes of fire. A circular dense white smoke rises like a ring, enlarging itself continually in an extremely beautiful manner, if the air is perfectly tranquil.

This gas burns with a green light, in nascent oxygenated muriatic acid gas, under the surface of water. Put

into a deep glass some phosphoret of lime, broken into pieces of the size of a pea, and add half as much oxygenated muriate of potash. Fill the vessel with water, and bring into contact with the materials at the bottom of the fluid some concentrated sulphuric acid. This may be most conveniently done, by letting the acid fall through a long funnel reaching to the bottom of the vessel. A soon as the decomposition of the water, and that of the oxygenated muriate takes place, flashes of fire dart from the fluid, and illuminate the bottom of the vessel with a beautiful green light.

A riband, impregnated with a solution of gold, may be gilt by the action of phosphorated hydrogen gas.

Nitrous gas. This name is given to an aeriform fluid, consisting of a certain quantity of nitrogen gas and oxygen; first described by Priestley, but in some measure known before to Hales.

It is colourless, having no sensible taste, and is neither acid nor alkaline: it cannot be respired. The greater number of combustible bodies cannot burn in it. It is nevertheless capable of supporting the combustion of some bodies. Phosphorus burns in it, when introduced in a state of inflammation; pyrophorus takes fire in it spontaneously.

To obtain it, put into a small retort some pieces of copper, and pour on them nitric acid diluted with water; an effervescence takes place, and nitrous gas will be produced. After having suffered the gas to escape for a few minutes, on account of the common air contained in the retort, collect the gas in the water apparatus as usual. In order to obtain this gas in a pure state, it should be shaken for some time in contact with water.

We have seen before, that water was decomposed on bringing in contact with it a metal and an acid. But here the case is different; the water suffers no alteration; on the contrary, the acid undergoes a partial decomposition; the metal robs the nitric acid of the greatest part of its oxygen, and becomes oxydated. The remainder of the acid having lost so much of its oxygen, becomes so altered, that, at the usual temperature, it can exist no longer in the liquid state, but instantly expands, and assumes the form of gas, ceasing at the same time to be an acid.

It was mentioned before, that nitrous gas greedily attracts oxygen gas from atmospheric air. During this union an acid is produced.

Pass up into a tall cylindrical glass vessel over water, about one part of nitrous gas and two of common air. The two fluids will speedily unite, red fumes will be produced, and the volume of the two combined gases will be diminished. A considerable degree of heat will be perceived, the water will rise in the vessel, and absorb the red vapours. When the two gases have mixed in proper proportion, nothing remains at last but the nitrogen gas of the atmospheric air.

Usually sixteen parts of common air are requisite to destroy completely seven of nitrous gas; this, however, varies according to the purity of the atmospheric air.

The nitrous gas, in this experiment, decomposes the atmospheric air; it takes the oxygen gas from the nitrogen gas, unites with it, and forms nitrous acid. The nitrous gas is therefore left behind; the heat which is generated, is that which kept the gases in solution, which is now set free.

If, instead of atmospheric air, oxygen gas is used, this experiment will be still more striking, and the gases will almost entirely disappear.

Upon this property which nitrogen gas has, of absorbing the oxygen of the atmosphere, Priestley formed the eudiometers, already mentioned.

Gaseous oxyd of azote, or nitrous oxyd. The union of azote, or nitrogen and oxygen, which we considered before under the name of nitrous gas, does not constitute the first degree of oxygenation of nitrogen. There is another degree below this. This was formerly called dephlogisticated nitrous gas, but now gaseous oxyd of nitrogen, or nitrous oxyd. It was first discovered by Priestley.

Professor Davy has examined with great accuracy the formation and properties of all the substances concerned in its production; and to him we are indebted for a thorough knowledge of this gas. We shall describe its principal properties as we find them in his Researches.

Gaseous oxyd of nitrogen is a permanent gas. A candle burns in it with a brilliant flame and crackling noise: before its extinction the white inner flame becomes surrounded with a blue one. Phosphorus introduced to it in a state of inflammation burns with increased splendour, as in oxygen gas. Sulphur introduced into it when burning with a feeble blue flame, is extinguished; but when in a state of vivid inflammation it burns with a rose coloured flame. Lighted charcoal burns in it more brilliantly than in atmospheric air. Iron wire with a small piece of wood affixed to it, and introduced inflamed into a vessel filled with this gas, burns rapidly, and throws out bright scintillating sparks.

Nitrous oxyd is rapidly absorbed by water which has been boiled; a quantity of gas equal to rather more than half the bulk of the water may be thus made to disappear; the water acquires a sweetish taste, but its other properties do not differ perceptibly from common water. The whole gas may be expelled again by heat. It does not change blue vegetable colours. It has a sweet taste, and a faint but agreeable odour.

This gas explodes with hydrogen, when electric sparks are made to pass through the mixture.

Animals, when confined wholly in this gas, give no signs of uneasiness at first, but they soon become restless, and then die.

When it is mingled with atmospheric air, and then received into the lungs, it generates highly pleasurable sensations: the effects it produces on the animal system are very extraordinary. It excites the body to action, and rouses the faculties of the mind, inducing a state of great exhiliration, an irresistible propensity to laughter, a rapid flow of vivid ideas, and unusual vigour and fitness for muscular exertions, in some respects resembling the sensations attendant on intoxication, without any languor, depression of spirits, or disagreeable feelings afterward, but more generally followed by vigour, and a disposition to exertion, which gradually subsides. The accounts of these wonderful effects, which, when first announced, were scarcely credited, have been confirmed by a variety of experiments, so as to be past all kind of doubt.

This gas is produced when substances, having a strong affinity with oxygen, are added to nitric acid, or to nitrous gas. It may therefore be obtained by various methods, in which nitrous gas or nitric acid is decomposed

by substances capable of attracting the greater part of their oxygen. The most commodious and expeditious, as well as the cheapest mode of obtaining it, is by decomposing nitrate of ammonia by heat in the following manner:

Put into a glass retort some pure nitrate of ammonia, and apply to it an Argand's lamp: the salt will soon liquefy, and when it begins to boil gas will be evolved. Increase the heat gradually, till the body and neck of the retort become filled with a milky white vapour. In this state the temperature of the fused nitrate is between 340 and 480 degrees. After the decomposition has proceeded for some minutes, so that the gas, when examined, quickly enlarges the flame of a taper, it may be collected over water. Care should be taken during the whole process never to suffer the temperature of the fused nitrate to rise above 500 degrees Fahrenheit, which may be easily judged of from the density of the vapours in the retort, and from the quick ebullition of the fused nitrate; for if the heat is increased beyond this point, the vapours in the retort acquire a reddish and more transparent appearance, and the fused nitrate begins to rise, and occupy twice the bulk it did before. The nitrous oxyd, after its generation, should stand over water for several hours, and is then fit for respiration, or other experiments.

To experience its effects in breathing it, put about a gallon into a large bladder, or oiled silk bag, having a tube attached to it of three fourths of an inch in diameter. First, the common air must be expelled from the lungs, before the tube is received into the mouth, and the nostrils must be accurately closed with the hand. It must then be breathed backward and forward into the bag for a few minutes.

Sulphureous acid gas is no where found in a natural state, and is entirely a production of art.

It is obtained by exposing to heat in a retort, sulphuric acid, while it is exercising an action on some combustible body, such as oil, charcoal, mercury, &c. in a word, on such bodies as can take up a portion of the oxygen combined with the sulphur contained in that acid. It is sulphur combined with a less quantity of oxygen than that which is necessary to make it *sulphuric* acid; the combustible body, therefore, takes a part of its oxygen from the sulphuric acid, which, by these means, becomes *sulphureous* acid; and caloric combining with this acid, causes it to assume the gaseous form. This process requires a mercurial apparatus, because this gas is entirely soluble in water.

Sulphureous acid gas is more than twice as heavy as atmospheric air. It extinguishes burning bodies, and suffocates animals immersed in it. It first reddens, and then destroys most of the vegetable colours. It has the property of whitening silk, and giving it a lustre.

Sulphureous acid gas combines with alkalies, and forms with them neutral salts, which differ from those produced by the sulphuric acid and the same alkalies, in their form, their savour, and particularly their property of being decomposed by the weakest acids, and even the acetous acid.

Muriatic acid gas is obtained by exposing to heat fuming muriated acid, put into a retort, the beak of which is introduced below a bell filled with mercury, and placed on the shelf of a mercurial pneumatic apparatus.

You may obtain it also with the same apparatus, if, instead of muriatic acid, you expose to heat a mixture of muriate of soda, or marine salt and sulphuric acid; the sulphuric acid combines with the soda the base of the marine salt, and the muriatic acid remaining free, passes into the state of muriatic acid gas.

Muriatic acid gas is perfectly soluble in water, and in a very short time. If you therefore introduce into the bell in which the gas has been collected, a small quantity of water, the latter, by its relative lightness, will rise to the surface of the mercury; the gas will be immediately absorbed entirely, and dissolved in the water; the mercury will ascend toward the top of the bell; and the liquor found above the mercury will be real muriatic acid, more highly concentrated, according as there is more gas and less water.

Muriatic acid gas, therefore, is nothing else than the muriatic acid itself deprived of water; that is to say, as much concentrated as possible, and combined with caloric, which causes it to assume the gaseous form.

Muriatic acid gas has a sharp pungent odour. If a little of it is mixed with atmospheric air, it produces, like the muriatic acid, white fumes or vapours, occasioned by the combination of the gas with the moisture of the air.

The base of the muriatic acid gas is strongly combined with oxygen, for which it has so great an affinity, that it cannot be separated from it. The nature of this base is therefore unknown. Its affinity for oxygen is so strong, that it can even combine itself with a larger quantity of oxygen than is necessary to constitute an acid, and it then appears in the form of oxygenated muriatic gas.

This gas is much heavier than atmospheric air. It gives the same signs of acidity as the muriatic acid itself; and this indeed ought to be the case, as it is the same substance. It reddens blue vegetable colours, but it destroys neither them nor any of the other colours, as the oxygenated muriatic gas does.

It combines with all the alkaline bases, and forms with them muriatic salts. If it is mixed with ammoniacal gas, it combines with it, and forms muriate of ammonia.

It suffocates animals immersed in it, and extinguishes a lighted taper; but it first enlarges its flame, and makes it appear of a green or bluish colour at the edges.

Oxygenated muriatic acid gas. The dephlogisticated muriatic acid of Scheele, under a gaseous form, is the muriatic acid gas surcharged with oxygen.

This gas is obtained by exposing the muriatic acid to heat and evaporation, whilst it is acting on a substance which contains oxygen; such, for example, as the native oxyd of manganese: if you therefore put black oxyd of manganese and muriatic acid into a glass retort, and expose them to heat, a strong fermentation will be excited, during which the muriatic acid will be converted into gas, but surcharged with oxygen, which is taken from the oxyd of the manganese, because it has a greater affinity for that substance.

It may be prepared in the water apparatus, though it is absorbable by water, if care is taken to fill the bells, or air jars, completely with the gas, and to leave no water in them.

Oxygenated muriatic gas is not invisible, like the other gases; it is of a greenish yellow colour, which renders it very perceptible.

This gas destroys vegetable colours entirely. All flowers, and the green leaves of plants, are rendered white by it, and alkali is not capable of restoring their colours.

This effect can only be ascribed to the absorption of oxygen. This gas, which contains oxygen in excess, gives up a part, which vegetable substances absorb with avidity, and by this absorption lose their colour. The oxygenated muriatic acid gas then becomes converted into common muriatic acid gas.

This property has given rise to a new method of bleaching, which has proved successful. The application of the oxygenated muriatic acid, either in the gaseous or the liquid state, has assisted the process of whitening thread, cotton, linen, wax, &c. in a surprising degree, and it is now very generally employed for this purpose.

To show its effects in bleaching, suspend some unbleached calico, or linen, moistened with water, in a jar filled with the gas; the natural colour of the cloth will soon begin to fade, and at last totally disappear. If different coloured patterns of printed calico are immersed for a few minutes in the gas, their colours will soon be destroyed, except those which are yellow.

Though oxygenated muriatic acid gas is exceedingly noxious to life, it does not extinguish combustion. If a burning taper, fixed to a wire, is immersed in it, the taper burns of a red colour, and more vividly than in atmospheric air: a greater quantity of smoke is emitted at the same time.

Fill a tall receiver, furnished with a ground stopper, with oxygenated muriatic acid gas over water, and let fall into it copper, in thin leaves, called Dutch gold. The leaf, before it reaches the bottom of the receiver, will burn with a pale green light.

Gold leaf may be burnt in the same manner. Copper wire, when heated to redness, also takes fire when introduced into the gas in that state.

Fluoric acid gas. The radical of fluoric acid gas is unknown. It may be obtained by decomposing fluate of lime, Derbyshire spar, by means of sulphuric acid. For this purpose, put one part of powdered fluate of lime into a leaden retort, and pour over it two or three parts of sulphuric acid. A violent action ensues, and fluoric acid gas is extricated, which must be collected over mercury, either in a leaden or tin vessel, or in a glass receiver covered within with a coat of varnish or wax. When no more gas is produced, the action of the acid must be assisted by a gentle heat.

The most remarkable property of this gas is its power of dissolving silex: it therefore dissolves glass crystals, and various precious stones. It is heavier than common air. It does not maintain combustion, nor can animals breathe it. It is absorbed by water, and forms with it liquid fluoric acid. It has a penetrating odour. It corrodes animal and vegetable substances. Light has no effect upon it. It emits white fumes, when in contact with moist atmospheric air. It reddens blue vegetable colours. With ammonia, it forms a concrete body. It has no action upon platina, gold, silver, mercury, tin, lead, antimony, cobalt, nickel, or bismuth; but it corrodes iron, arsenic, and manganese.

The property of dissolving silex has caused it to be applied to etching on glass, which is done either by means of the fluoric acid gas, or liquid fluoric acid.

AIR BALLOON, a general name given to bags or other light substances filled with an aerial fluid. The art of flying, or of imitating the feathered tribe, has long been the object of earnest desire amongst men. Cars, artificial birds, wings, and other mechanisms for flying, generally absurd, and always insufficient, have frequently been exhibited to the undistinguishing eye of the vulgar; but the strictest inquiry into the accounts of authentic history, finds no mention of any success having ever attended the attempts of this nature previous to the year 1782. The recent discoveries made on the nature and properties of aerial fluids, by the industry of Black, Priestley, Cavendish, and others, suggested, some time before the above mentioned year, the practicability of forming machines sufficient to elevate considerable weights into the regions of the atmosphere. Mr. Cavendish was the first who ascertained the specific gravity of hydrogen gas, then called inflammable air, and found it to be a vast deal lighter than common air. His experiments on this subject are published in the Philosophical Transactions for the year 1766. In consequence of this discovery, it was natural to conclude, that if a large bladder, or other envelope, was filled with hydrogen gas, and that if the weight of the envelope added to that of the contained gas, was less than the weight of an equal bulk of common air, the apparatus would mount up into the atmosphere, for the same reason, and in the same manner, as a cork would rise from the bottom toward the surface of the sea, supposing the cork was left at liberty in the former place.

Dr. Black of Edinburgh thought of filling the allantois of a calf with hydrogen gas, for the purpose of showing at his lectures that such a body would ascend into the atmosphere; but he never put the project to the test of actual experience.

Early in the year 1782, Mr. Cavallo made the first attempts to elevate a bag full of hydrogen gas into the surrounding air, and an account of his experiments was read at a meeting of the Royal Society on the 20th of June, 1782.

The weight of hydrogen gas, the mean weight of atmospherical air, and the weight of the substance of which the vessel or bag is to be formed, being ascertained, it is easy from those particulars to determine by calculation the dimensions of a vessel, which, when filled with hydrogen gas, might be lighter than an equal bulk of common air.

Upon this principle Mr. Cavallo tried bladders, the thinnest and largest that could be procured. Some of them were cleaned with great care, removing from them all the superfluous membranes, and other matter that could possibly be scraped off; but notwithstanding all those precautions, he found the largest and lightest of those prepared bladders to be somewhat too heavy for the purpose. Some swimming bladders of fishes were also found too heavy for the experiment; nor could he even succeed to make any durable light balls by blowing hydrogen gas into a thick solution of gums, thick varnishes, and oil paint. In short, soap balls, inflated with hydrogen gas, were the only things of this sort which he could elevate in air; and these perhaps were the first air balloons that were ever constructed.

Not long after this, news was received from France of the success which had attended an experiment of a similar nature made at Avignon, by Stephen Montgolfier; but the bag was not filled with hydrogen gas. It was filled with air rarefied by heat, which of course was lighter

than an equal bulk of common air of the usual temperature.

It is said that the two brothers, Stephen and John Montgolfier, began to think on the experiment of the aerostatic machine as early as the middle or latter end of the year 1782. The natural ascension of smoke, and of the clouds in the atmosphere, suggested the first idea; and to imitate those bodies, or to enclose a cloud in a bag, so that the latter might be elevated by the buoyancy of the former, was the first project of those celebrated gentlemen.

Stephen Montgolfier, the eldest of the two brothers, made the first aerostatic experiment at Avignon, toward the middle of November, 1782. The machine consisted of a bag of fine silk, in the shape of a parallelopipedon, open on one side, the capacity of which was equal to about 40 cubic feet. Burning paper, applied to its aperture, served to rarefy the air, or to form the cloud; and, when sufficiently expanded, the machine ascended rapidly to the ceiling of the room. Thus the original discovery was made, which was afterward confirmed, improved, and diversified, by different persons in different parts of the world.

As soon as the news of Mr. Montgolfier's successful experiment reached Paris, the scientific persons of that capital, justly concluding that a similar experiment might be made by filling a bag with hydrogen gas, immediately attempted to verify the supposition. A subscription for defraying the expenses that might attend the accomplishment of the project, was immediately opened; persons of all ranks ran with eagerness to sign their names, and the necessary sum was speedily raised. Mess'rs. Roberts were appointed to construct the machine, and Mr. Charles, professor of experimental philosophy, was appointed to superintend the work.

The obstacles, which opposed the accomplishment of this first attempt, were many; but the two principal difficulties were to produce a large quantity of hydrogen gas, and to find a substance sufficiently light to make the bag of, and at the same time impermeable to the gas. At last they constructed a globular bag of a sort of silk stuff, called *lutestring;* which, in order to render it impervious to the gas, was covered with a certain varnish, said to consist of dissolved elastic gum. The diameter of this bag, which, from its ball like shape, was called a *balloon*, and from this the name *air balloons* was derived, was 12 feet two inches French, or about 13 feet English. It had only one aperture, like the neck of a bladder, to which a stop cock was adapted. The weight of the balloon, when empty, together with the stop cock, was 25 pounds.

The attempts to fill this bag commenced on the 23d of August, 1783. But the operators met with many difficulties and disappointments, from inadvertences, want of materials, want of precaution, &c. so much so, that the accomplishment of the experiment, *viz.* the actual ascent of the balloon, did not take place before the 26th of the same month. On the morning of that day the inflated balloon, having a small cord fastened to its neck, was permitted to rise only to the height of about 100 feet; but at five o'clock in the afternoon of the 27th, the balloon was disengaged from its fastenings, in the Champ de Mars, and rose majestically in the atmosphere before the eyes of a great many thousand spectators, and amidst a copious shower of rain. In about two minutes time it rose to the height of about 3123 feet. After remaining in the atmosphere only $\frac{3}{4}$ of an hour, this balloon fell in a field near Gonesse, a village about 15 miles from Paris. Its fall was attributed to a rupture that was found in it, and it was reasonably imagined, that the expansion of the hydrogen gas, when the balloon had reached a much less dense part of the atmosphere, had burst it. When this balloon went up, it was found upon trial to be 35 pounds lighter than an equal bulk of common air.

Thus in the years 1782 and 1783, it was ascertained that bags full of hydrogen gas, or of rarefied common air, either of which is lighter than common air in its usual state, would ascend into the atmosphere, and that they might take up considerable weights.

Soon after the success of the first attempt, the Montgolfiers repeated the experiment in the open air, and with bags of different sizes; but their first grand and public exhibition in the presence of a very respectable and numerous assembly, was made on the 5th of June, 1783, with an aerostatic machine or bag that measured 35 feet in diameter. The machine, inflated by the rarefied air, ascended to a considerable height, and then fell at the distance of 7668 feet from the original place of ascension. This experiment was described and recorded with great accuracy; and accounts of it were immediately forwarded to the court of France, to the academy of sciences, and almost as far as literary and entertaining correspondence could reach. The younger Montgolfier, arriving at Paris not long after the above mentioned public exhibition, was invited by the academy of sciences to repeat his singular aerostatic experiment; in consequence of which invitation, that gentleman began to construct an aerostatic machine of about 72 feet in height, at the expense of the academy. But while this operation was going on, and as a successful experiment with an inflammable air balloon had already been performed on the 27th of August, the project of making balloons became general; and those who wished to make the experiment on the smallest scale soon calculated the necessary particulars, and found that the performance of the experiment was far from being either difficult or expensive. The Baron de Beaumanoir, at Paris, by the suggestion of a Mr. Deschamps, was induced to try gold beater's skin, and soon made a balloon by gluing several pieces of that skin together. This balloon was no more than 19 inches in diameter; it was of course easily filled with hydrogen gas; and on the 11th of September, 1783, it mounted with rapidity into the atmosphere.

Mr. Montgolfier, having completed his large balloon, agreeably to the desire of the academy, made a private experiment with it on the 11th of September, which succeeded. On the following day another experiment was made with the same, before the commissaries of the academy, and a vast number of other spectators; but this experiment, in consequence of a violent shower of rain, was attended with partial success: and the aerostat was considerably damaged.

A similar machine was speedily constructed by the same Mr. Montgolfier, by whom the experiment was performed at Versailles on the 19th of September, before the royal family of France, and an innumerable concourse of

spectators. The preparation for filling the machine with rarefied air consisted of an ample scaffold, raised some feet above the ground; in the middle of which there was a well or chimney, about 16 feet in diameter; in the lower part of which, near the ground the fire was made. The aperture of the balloon was put round the chimney or well, and the rest of it was laid down over the well and the surrounding scaffold. As soon as the fire was lighted the machine began to swell, acquired a convex form, stretched itself on every side, and in 11 minutes time, the cords being cut, the machine ascended, together with a wicker basket or cage, which was fastened to it by means of a rope, and in which a sheep, a cock, and a duck, had been placed. These were the first animals that ever ascended with an aerostatic machine. The apparatus rose to the height of about 1,440 feet, and remained in the atmosphere during eight minutes; then fell at the distance of about 10,200 feet from Versailles, with the animals safe in the basket.

After the success of this experiment with the animals, &c. and when ten months had scarcely elapsed since Mr. Montgolfier made his first experiment of this sort, Mr. Pilatre de Rozier publicly offered himself to be the first adventurer in the newly invented machine. His offer was accepted, his courage remained undaunted, and on the 15th of October, 1783, he actually ascended into the atmosphere, to the astonishment of a gazing multitude. The balloon with which he ascended was of an oval shape, its height being about 74, and its horizontal diameter 48 feet. The aperture or lower part of the machine had a wicker gallery about three feet broad, with a balustrade both within and without, about three feet high. The inner diameter of this gallery, and of the neck of the machine which passed through it, was nearly 16 feet. In the middle of this aperture an iron grate or brazier was supported by means of chains, which came down from the sides of the machine. In this construction, when the machine was up in the air, with a fire lighted in the grate, it was easy for a person who stood in the gallery, and had fuel with him, to keep up the fire in the opening of the machine, by throwing the fuel on the grate through port holes made in the neck of the machine; by which means the machine might be kept up as long as the person in its gallery thought proper, or till he had no fuel to supply the fire with.

The first aerial voyage with an inflammable air balloon, was performed subsequent to the above mentioned experiment, *viz.* on the 1st of December, 1783. Mr. Charles and Mr. Robert, who had constructed a balloon of this sort, as has been already mentioned, were the first adventurers. The balloon was globular, its diameter being 27½ feet. A net went over the upper hemisphere, and was fastened to a hoop, which went round the middle of the balloon. From this hoop ropes proceeded, and were fastened to a boat which swung a few feet below the balloon. In order to prevent the bursting of the machine by the expansion of the gas in an elevated region, a valve was made on the upper part of it, which, by pulling a string, would open and let out part of the gas. There was likewise a long silken pipe, through which the balloon was filled.

The apparatus for filling it consisted of several wooden casks placed round a large tub full of water, every one of which had a long tin tube, which terminated under a vessel or funnel, that was inverted into the water of the tub. A tube then proceeded from this funnel, and communicated with the balloon, which stood just over it. Iron filings and diluted sulphuric acid were put into the casks; and the gas which was extricated from those materials passed through the tin tubes, then through the water of the tub, and, lastly, through the tube of the funnel into the balloon. See the Plate, fig. 1.

When Mess'rs. Charles and Robert placed themselves in the boat, they had with them proper philosophical instruments, provisions, clothing, and some bags full of sand, by way of ballast. With this preparation they ascended at three quarters after one o'clock. At the time they went up, the thermometer, Fahrenheit's scale, stood at 52 degrees, the mercury in the barometer stood at 27 inches, from which they deduced their altitude to be nearly 600 yards. During the rest of their voyage the mercury in the barometer moved generally between 27 inches and 27,65; rising and falling according as part of the ballast was thrown out, or some gas escaped from the balloon. The thermometer stood generally between 53 and 57 degrees.

Soon after their ascent they remained stationary for a short time; they then went horizontally, in the direction of N.N.W. They crossed the Seine, and passed over several towns and villages, to the great astonishment of the inhabitants, who did not expect to see such a spectacle, and who had perhaps never heard of this new sort of experiment. This delicious aerial voyage lasted one hour and three quarters. At last they descended in a field near Nesle, a small town, about 27 miles distant from Paris; so that they had gone at the rate of about 15 miles per hour, without feeling the least inconvenience; and the balloon underwent no other alteration than what was occasioned by the dilatation and contraction of the gas, according to the vicissitudes of heat and cold.

The success of the experiments, which have been already described, spread a universal enthusiasm throughout Europe; and the aerostatic experiments, both in the diminutive and in the large way, were soon undertaken in different countries. The first experiment of this kind was exhibited in London on the 25th of November, 1783, when an inflammable air balloon, 10 feet in diameter, was sent up by count Zambeccari, an Italian gentleman. The first aerial voyage undertaken in England, with an inflammable air balloon of 33 feet in diameter, made of oil silk, was performed by Mr. Lunardi, another Italian, on the 15th of September, 1784.

The abbe Bertholon seems to have been the first person who made use of small balloons for exploring the electricity of the atmosphere, which must be a very useful method, particularly in calm weather, when electrical kites cannot be raised. He raised several air balloons, to which long and slender wires were attached, the lower extremity of the wire being fastened to a glass stick or other insulated stand, whereby he obtained from such wires electricity enough to show its kind, and even sparks.

On the 13th of January, 1784, an aerostatic machine, of about 37 feet in height, and 20 in diameter, was launched from the castle De Pisancon, near Romans, in Dauphiny. It rose with surprising velocity, and as the wind was north, it went southward; but when the machine had ascended to the height of about 1300 feet, it went back toward the north, and in less than five minutes time it as-

cended to the height of above 6000 feet. In less than ten minutes it fell at the distance of nearly four miles.

This experiment, and indeed the similar success of many others, shows that there frequently are in the atmosphere currents of air in different, and sometimes quite opposite directions; this, however, is far from being always the case. If different currents could always be met with at different heights above the surface of the earth, the method of guiding balloons would be extremely easy; for the aerial traveller would have nothing more to do than to place himself in the favourable current, which he might do by throwing out either some ballast or some inflammable gas, according as he wished to go higher or lower.

The largest aerostatic machine ever made, and filled with rarefied air, was launched at Lyons on the 19th of January, 1784, with not less than seven persons in its gallery, amongst whom were Joseph Montgolfier and Pilatre de Rozier. The height of this machine was about 131 feet, and its horizontal diameter about 104. Its weight, when it ascended, including passengers, gallery, &c. was about 1600 pounds.

This machine, having suffered considerably in consequence of previous trials, was by no means in a perfect state when it ascended; nevertheless, when the action of the fire had inflated it, the seven persons, who in spite of every remonstrance had placed themselves in the gallery, refusing to relinquish their places, the machine was released from the ropes which confined it, and ascended majestically into the atmosphere. At a certain height, the wind turned it toward the west: but it afterward proceeded east-south-east, ascending at the same time, until it was at least 1000 yards high.

The effect which was produced on the spectators by this spectacle is described as the most extraordinary that was ever occasioned by any production of human invention. It was a mixture of the strangest nature imaginable. Vociferations of joy, shrieks of fear, expressions of applause, the sound of martial instruments, and the discharge of mortars, produced an effect more easily imagined than described. Some of the spectators fell on their knees, and others elevated their suppliant hands to the heavens; some women fainted, and many wept; but the confident travellers, without showing the least appearance of fear, were continually waving their hats out of the gallery.

At about fifteen minutes after the ascent, the wind shifted again; but it was so feeble that the machine stood almost stationary for about four minutes. Unfortunately about this time a rent was made in the machine, which occasioned its descent; and when it came within 600 feet of the ground, its velocity was considerably accelerated. It is said that no less than 60,000 persons, besides the Marechaussee, ran to the spot, with the greatest apprehension for the lives of the adventurous aerial travellers. They were immediately helped out of the gallery, and luckily no person had received any hurt, except Mr. Montgolfier an insignificant scratch. The machine was torn in several places, besides a vertical rent of upward of 50 feet in length, which clearly shows how little danger is to be apprehended from the use of those machines, especially when they are properly constructed and judiciously managed.

On the 5th of April, 1784, Mess'rs. de Morveau and Bertrand, at Dijon, ascended with an inflammable air balloon, which, according to their barometrical observations, seems to have reached the extraordinary height of 13,000 feet, when the cold was so great that the thermometer stood at 25°.

On the 15th of July, the duke de Chartres, the two brothers Roberts, and another person, ascended with an inflammable air balloon, from the park of St. Cloud, at 52 minutes past seven in the morning. This balloon was of an oblong form, its dimensions being 55 feet by 34. It ascended with its greatest extension nearly horizontal; and after remaining in the atmosphere about 45 minutes, it descended at a small distance from its place of ascension. But the incidents that occurred during this aerial excursion deserve particular notice, as nothing like it had happened before to any of the aerial travellers. This machine contained an interior small balloon, filled with common air; by which means it was supposed that they might regulate the ascent and the descent of the machine, without any loss of the hydrogen gas, or of ballast. The boat was furnished with a helm and oars, that were intended to guide the machine, but which were in this, as well as in every other similar attempt, found to be quite useless.

On the level of the sea, the mercury in the barometer stood at 30,25 inches, and at the place of ascension it stood at 30,12. Three minutes after its ascension, the balloon was lost in the clouds, and the aerial voyagers lost sight of the earth, being involved in a dense vapour. Here an unusual agitation of the air, somewhat like a whirlwind, in a moment turned the machine three times from the right to the left. The violent shocks which the adventurers suffered, prevented their using any of the means prepared for the direction of the machine; and they even tore away the silk stuff of which the helm was made. Never, said they, a more dreadful situation presented itself to any eye, than that in which they were involved. An unbounded ocean of shapeless clouds rolled beneath, and seemed to forbid their return to the earth, which was still invisible. The agitation of the balloon became greater every moment. They cut the cords which held the interior balloon, which consequently fell on the bottom of the external balloon, just upon the aperture of the tube that went down to the boat, and stopped that communication. At this time the thermometer was a little above 44°. A gust of wind from below drove the balloon upward, to the extremity of the vapour, where the appearance of the sun showed them the existence of nature; but now both the heat of the sun, and the diminished density of the atmosphere, occasioned such a dilatation of the gas, that the bursting of the balloon was apprehended; to avoid which, they introduced a stick through the tube, and endeavoured to remove the inner balloon, which stopped its aperture within the external balloon; but the dilatation of the gas pressed the inner balloon so forcibly against that aperture, as to render every attempt ineffectual. During this time, they continually ascended, until the mercury in the barometer stood not higher than 24,36 inches, which showed their height above the earth to be about 5,100 feet. In these dreadful circumstances they thought it necessary to make a hole in the balloon, in order to give exit to the gas; and accordingly the duke

himself, with one of the spears of the banners, made two holes in the balloon, which opened a rent of about seven or eight feet. In consequence of this, they then descended rapidly, seeing at first no object either on earth or in the heavens; but a moment after, they discovered the fields, and that they were descending straight into a lake, wherein they would inevitably have fallen, had they not quickly thrown over about 60 pounds weight of ballast, which occasioned their coming down at about 30 feet beyond the edge of the lake. Notwithstanding this rapid descent, none of the four adventurers received any hurt; and it is remarkable, that out of six glass bottles full of liquor, which were simply laid down in the boat, one only was found broken.

In the course of the summer of 1784, two persons, *viz.* one in Spain, and another near Philadelphia, in America, were very near losing their lives by going up with rarefied air machines. The former, on the 5th of June, was scorched by the machine taking fire, and was hurt by the subsequent fall, so that his life was long despaired of. The latter, having ascended a few feet, was wafted by the wind against the wall of a house, and some part of the machinery was entangled under the eaves, from which he could not extricate it. At last the great ascensional power of the machine broke the ropes or chains, and the man fell from the height of about 20 feet. The machine presently took fire, and was consumed.

We shall now relate one of the most remarkable aerial voyages that were ever made with an aerostatic machine. It is the crossing of the English channel in an inflammable air balloon of 27 feet diameter. The adventurer in this dangerous voyage was Mr. Blanchard, an intrepid Frenchman, who had already made five other aerial voyages with the very same balloon, both in France and in England. Mr. Blanchard is remarkable for having made a greater number of aerial voyages in England, in France, and elsewhere, both before and after the crossing of the English channel, than any other person recorded in the history of aerostation. The only trial worth remarking which Mr. Blanchard appears to have made in his aerial excursions, is the ineffectual use of oars, wings, &c. for directing the balloon. Profit seems to have been the principal, if not the sole object of his numerous excursions.

On Friday the 7th of January, 1785, being a fine clear morning, after a sharp frosty night, and the wind being about N.N.W. though hardly perceptible, Mr. Blanchard, accompanied by Dr. Jeffries, an American gentleman, departed in the old balloon of 27 feet diameter, from Dover castle, directing their course for the French coast. Previous to the departure, the balloon, with the boat containing the two travellers, several necessaries, and some bags of sand for ballast, were placed within two feet of the brink of the perpendicular cliff before the castle. At one o'clock the intrepid Blanchard desired the boat, &c. to be pushed off; but the weight being too great for the power of the balloon, they were obliged to throw out a considerable quantity of ballast, in consequence of which they at last rose gently and majestically, though making very little way, with only three bags of ballast of ten pounds weight each. At a quarter after one o'clock, the barometer, which on the cliff stood at 29,7, was fallen to 27,3; and the weather proved fine and warm. Dr. Jeffries describes with rapture the prospect which at this time was before their eyes. The country to the back of Dover, interspersed with towns and villages, of which they could count 37, made a beautiful appearance. On the other side the breakers, on the Goodwin Sands, appeared formidable. Upon the whole, they enjoyed a view perhaps more extended and diversified than was ever beheld by mortal eye. The balloon was much distended, and at 50 minutes past one o'clock was descending, in consequence of which they were obliged to throw out one bag and a half of sand. They were at this time about one third of the way from Dover, and had lost distinct sight of the castle. Not long after, finding that the balloon was descending very fast, all the remaining ballast was thrown over, as also a parcel of books, in consequence of which the balloon rose again. They were now at about half way. At a quarter past two o'clock, the rising of the mercury in the barometer showed that they were descending; in consequence of which the remaining books were thrown into the sea. At 25 minutes after two, they were at about three fourths of the way, and an enchanting view of the French coast appeared before their eyes; but the lower part of the balloon was collapsed, owing to the loss or condensation of the gas, and the machine was descending, which obliged them to throw over provisions for eating, the oars or wings of the boat, and other articles. "We threw away," said Dr. Jeffries, "our only bottle, which, in its descent, cast out a steam like smoke, with a rushing noise; and when it struck the water, we heard and felt the shock very perceptibly on our car and balloon." But the balloon still approaching the sea, they began to strip and cast away their clothes. They even intended to fasten themselves to the cords, and cut the boat away, as their last resource; but at this critical point, they had the satisfaction to observe that they were rising; their distance from the French shore, which they were approaching very fast, was about four miles. Fear was now vanishing apace; the French land showed itself every moment more beautiful, more distinct, and more extended; Calais, and above 20 other towns and villages, were clearly distinguished. Exactly at three o'clock they passed over the high grounds about midway between Cape Blanc and Calais; and it is remarkable that the balloon at this time rose very fast, and made a magnificent arch; probably owing to the heat of the land, which rarefied in some measure the hydrogen gas. At last they descended as low as the tops of the trees, in the forest of Guinnes, and opening the valve for the escape of the gas, they soon after descended safe to the ground, after having accomplished an enterprise which will probably be recorded to the remotest posterity.

The following is the melancholy account of an experiment which was attended with the death of two aerial adventurers, one of whom was Mr. de Rozier, the first person that ever ascended with an aerostatic machine.

Mr. Pilatre de Rozier, desirous of diversifying and improving the new method of travelling through the air, formed a plan of combining the two species of aerostatic machines, from which he expected to render their joint buoyancy more lasting, and of course more useful. His plan was to place an inflammable air balloon at top, and to affix to it by means of ropes, a rarefied air balloon, so that a space of several feet might intervene between the two. The passenger or passengers were intended to take their

places in the gallery of the lower machine, whence they could regulate the fire, and might by a proper management of the fuel, elevate or depress the whole, without the necessity of losing any inflammable gas from the upper balloon.

Accordingly this plan was put in execution. The upper or inflammable air balloon was of varnished silk, lined with a fine membrane, like gold beater's skin. The other balloon was of strong linen. On the 15th of June, 1785, at seven o'clock in the morning, every thing being ready, Mr. Pilatre de Rozier and a Mr. Romain, placed themselves in the gallery of the balloon, with plenty of fuel, instruments, and other necessary articles, and rose in the atmosphere. The machine seemed to take the best possible direction, but the wind being both feeble and shifting, they changed their direction two or three times; but when they were at a considerable height, and not above $\frac{3}{4}$ of a mile from the place of ascension, the machine appeared to be in flames, and presently the whole was precipitated down to the ground. The unfortunate adventurers were instantly killed, their bones disjointed and dreadfully mangled by the tremendous fall.

How this inflammable air took fire, is variously conjectured; but it is natural to suppose, that the sparks of fire must have flown from the lower to the upper or inflammable air balloon. On the ground, the bag of the upper balloon was in great measure burned or scorched; that of the lower was entire.

Omitting the various uninteresting, though not numerous aerial voyages undertaken in various parts of the world, during the 17 years subsequent to the above mentioned dreadful accident of Pilatre de Rozier and Mr. Romain, we shall only add the account of two aerostatic experiments lately performed in England by Mr. Garnerin, a French aeronaut. The first of these is remarkable for the very great velocity of its motion; the second for the exhibition of a mode of leaving the balloon, and of descending with safety to the ground.

On the 30th of June, 1802, the wind being strong, though not impetuous, Mr. Garnerin and another gentleman ascended with an inflammable air balloon from Ranelagh gardens on the southwest of London, between four and five o'clock in the afternoon; and in exactly three quarters of an hour they descended near the sea, at the distance of four miles from Colchester. The distance of that place from Ranelagh is sixty miles: therefore they travelled at the astonishing rate of 80 miles per hour. It seems that the balloon had power enough to keep them up four or five hours longer, in which time they might have gone safe to the continent; but prudence induced them to descend when they discovered the sea not far off.

The singular experiment of ascending into the atmosphere with an inflammable air balloon, and of descending with a machine called a parachute, was performed by Mr. Garnerin on the 21st of September, 1802. He ascended from St. George's Parade, North Audley street, and descended safe into a field near the small pox hospital at Pancras.

The balloon was of the usual sort, *viz.* of oiled silk, with a net, from which ropes proceeded, which terminated in or were joined to, a single rope at a few feet below the balloon. To this rope the parachute was fastened in the following manner.

The reader may easily form to himself an idea of this parachute, by imagining a large umbrella of canvas of about 30 feet in diameter, but destitute of the ribs and handle. Several ropes of about 30 feet in length, which proceeded from the edge of the parachute, terminated in a common joining, from which shorter ropes proceeded, to the extremities of which a circular basket was fastened, and in this basket Mr. Garnerin placed himself. Now the single rope, which has been said above to proceed from the balloon, passed through a hole in the centre of the parachute, also through certain tin tubes, which were placed one after the other in the place of the handle or stick of an umbrella, and was lastly fastened to the basket; so that when the balloon was in the air, by cutting the end of this rope next to the basket, the parachute, with the basket, would be separated from the balloon, and, in falling downward, would be naturally opened by the resistance of the air. The use of the tin tubes was to let the rope slip off with greater certainty, and to prevent its being entangled with any of the other ropes, as also to keep the parachute at a distance from the basket.

The balloon began to be filled at about two o'clock. There were 36 casks filled with iron filings and diluted sulphuric acid, for the production of the hydrogen gas. These communicated with three other casks or general receivers, to each of which was fixed a tube that emptied itself into the main tube attached to the balloon.

At six, the balloon being quite full of gas, and the parachute, &c. being attached to it, Mr. Garnerin placed himself in the basket, and ascended majestically amidst the acclamations of innumerable spectators. The weather was the clearest and pleasantest imaginable; the wind was gentle and about west by south; in consequence of which Mr. Garnerin went in the direction of about east by north. In about eight minutes time, the balloon and parachute had ascended to an immense height, and Mr. Garnerin, in the basket, could scarcely be perceived. While every spectator was contemplating the grand sight before them, Mr. Garnerin cut the rope, and in an instant he was separated from the balloon, trusting his safety to the parachute.

At first, *viz.* before the parachute opened, he fell with great velocity; but as soon as the parachute was expanded, which took place a few moments after, the decent became very gentle and gradual. In this descent a remarkable circumstance was observed, namely, that the parachute with the appendage of cords and basket, soon began to vibrate like the pendulum of a clock, and the vibrations were so great, that more than once the parachute, and the basket with Mr. Garnerin, seemed to be on the same level, or quite horizontal, which appeared extremely dangerous: however, the extent of the vibrations diminished as he came pretty near the ground. On coming to the earth, Mr. Garnerin experienced some pretty strong shocks, and when he came out of the basket, he was much discomposed; but he soon recovered his spirits, and remained without any material hurt.

As soon as the parachute was separated from the balloon, the latter ascended with great rapidity, and, being of an oval form, turned itself with its longer axis into an horizontal position.

In July, 1803, Mr. Garnerin made his thirty-third aerial excursion from Petersburg, accompanied by Mrs.

Garnerin, and his thirty-fifth from Moscow. During the latter, a huntsman, who spied him, fired at him, which induced him to descend. Omitting to notice several other aerial voyages undertaken since that time by different aeronauts, several of whom were actuated by a zeal for extending scientific observation; we will confine ourselves to two *nocturnal* excursions of the same intrepid Mr. Garnerin. He ascended from Tivoli, at Paris, on the 4th of August, 1807, at 11 o'clock in the evening, bearing the Russian flag, as a token of the peace that subsisted at that time between France and Russia. His balloon was illuminated by twenty lamps. placed at such distance as to obviate all danger from their communication with the hydrogen gas. He ascended to the height of 15,000 feet above the earth, and descended in seven hours and a half from his departure, near Loges, 45 leagues distant from Paris.

Mr. Garnerin undertook a second nocturnal voyage, on the 21st. September, of the same year, in the course of which he was exposed to the most imminent danger. Prognosticating an approaching storm, from the state of the atmosphere, Mr. Garnerin refused to be accompanied, though earnestly solicited. He ascended alone, from Tivoli, at 10 o'clock, and was carried up with astonishing rapidity to an immense height above the clouds. The balloon was then dilated to an alarming degree, and Mr. Garnerin having been prevented, by the turbulence of the mob, before his ascent, from regulating those parts of the apparatus which were meant to conduct the gas away from the lamps on its escape, was totally incapable of managing the balloon. He had no alternative left, therefore, but with one hand to make an opening two feet in diameter, through which the inflammable air was discharged in great quantities; and, with the other, to extinguish as many of the lamps as he could possibly reach. The aeronaut was now without a regulating valve; and the balloon, subject to every caprice of the whirlwind, was tossed about from current to current. When the storm impelled him downward, he was compelled to throw out his ballast, to restore the ascending tendency. In this forlorn condition the balloon rose through thick clouds, and afterward sunk, and the car, having struck against the ground, with a violent impulse, rebounded from it to a considerable altitude. The fury of the storm dashed him against the mountains; and, after many rude agitations and severe shocks, he was reduced to a state of temporary insensibility. On recovering from his perilous situation, he reached Mont Tonnerre, in a thunder storm. A very short time after, his anchor hooked in a tree; and, in seven hours and a half, after a voyage which had nearly proved fatal to him, he landed at the distance of 300 miles from Paris. (*a*)

We shall conclude this article with a description of the several figures on the plate, to which we have before occasionally referred. Figure 1 represents a balloon D F, suspended by means of the poles G and H, and the cord, for the purpose of being filled with gas. It is kept steady and held down whilst filling by ropes, which are readily disengaged. A, A, are two tubs about three feet in diameter, and two feet deep, inverted in larger tubs, B, B, full of water. At the bottom of each of the inverted tubs there is a hole, to which is inserted a tin tube; to these the silken tubes of the balloon are tied. Each of the tubs, B, is surrounded by several strong casks, so regulated in number and capacity, as to be less than half full when the materials are equally distributed. In the top of these casks are two holes; to one of which is adapted a tin tube. formed so as to pass over the edge of the tub B, and through the water, and to terminate with its aperture under the inverted tub A. The other hole, which serves for supplying the cask with materials, is stopped with a wooden plug. When the balloon is to be filled, the common air is first to be expelled, then the silken tubes are fastened round the tin ones: the iron filings are to be put into the casks, then the water, and lastly the sulphuric acid. The balloon will speedily be inflated by the hydrogen gas, and support itself without the aid of the rope G H. As the filling advances, a net is adjusted about it, the cords proceeding from the net are fastened to the hoop M N, the boat I K is suspended from the hoop, and whatever is wanted for the voyage is deposited in the boat. When the balloon is sufficiently full, the silken tubes are separated from the tin tubes, their extremities are tied, and they are placed in the boat. When the aeronauts are seated in the boat, the ropes that held the balloon down are slipped off, and the machine ascends in the air as in figure 2. In figure 3, is a representation of a part of Mr. Garnerin's balloon in its ascent, to which is attached the parachute, in its contracted state, and below is the car. Figure 4, shows the manner in which Mr. Garnerin descended in the car by means of the expanded parachute, after he had detached it from the balloon. In figure 5 is represented an apparatus as described by Mr. Cavallo, for filling balloons of the size of two or three feet in diameter with inflammable air, after passing it through water. A is a bottle with the ingredients; B C D a tube fastened in the neck at B, and passing through C, the cork of the other bottle, in which there is a hole made to receive the tube, and to this the balloon is tied. Thus the inflammable air coming out of the tube D, will pass first through the water of the bottle E, and then into the balloon. Two small casks may be used instead of the bottles A and E.

To obtain the gas from the coarser kind of materials, the following apparatus may be recommended. Let a vessel be made of iron in the shape of a Florence flask, figure 6. Put the substance into this vessel, so as to fill about three fourths of its cavity. Lute a tube of brass to the neck C of the vessel, and let the end D of the tube be shaped as in the figure, so that going into the water H I, it may terminate under a sort of inverted vessel, E F, to the upper aperture of which the balloon G is adapted. If now the part A B of the vessel is put into the fire, and made red hot, the inflammable air produced will come out of the tube C D, and passing through the water will at last enter into the balloon G.

AIR GUN. See Pneumatics.

AIR JACKET, a sort of jacket made of leather, in which are several bags, or bladders, composed of the same materials, communicating with each other. These are filled with air through a leather tube, having a brass stop cock accurately ground at the extremity, by which means the air blown in through the tube is confined to the bladders. The jacket must be wet before the air is blown into the bags, as otherwise it will immediately escape through the pores of the leather. By the help of these bladders, which are placed near the breast, the person is supported in the water, without making any effort to swim.

AIR PIPES, an invention for drawing foul air out of ships, or any other close places, by means of fire. These pipes were first discovered by a Mr. Sutton, a brewer in London; and from him have got the name of *Sutton's Air pipes*. The principle on which their operation depends is no other than that air is necessary for the support of fire; and, if it has not access from the places most adjacent, will not fail to come from those that are more remote. Thus, in a common furnace, the air enters through the ash hole; but if this is closed up, and a hole made in the side of a furnace, the air will rush in with great violence through that hole. If a tube of any length whatever is inserted in this hole, the air will rush through the tube into the fire, and of consequence there will be a continued circulation of air in that place where the extremity of the tube is laid. Mr. Sutton's contrivance then amounts to this. As, in every ship of any bulk, there is already provided a copper or boiling place proportionable to the size of the vessel; it is proposed to clear the bad air by means of the fire already used under the coppers or boiling places for the necessary uses of the ship. It is well known, that, under every such copper or boiler, there are placed two holes, separated by a grate; the first of which is for the fire, and the other for the ashes falling from it; and that there is also a flue from the fire place upward, by which the smoke of the fire is discharged at some convenient place of the ship. It is also well known, that the fire once lighted in these fire places, is only preserved by the constant draught of air through these two holes and flue; and that if the holes are closely stopped up, the fire, though burning ever so briskly before, is immediately put out. But if, after shutting up these holes, another hole is opened, communicating with any other room or airy place, and with the fire, it is clear the fire must burn as before, there being a like draught of air through it as there was before the stopping up of the first holes. It is therefore proposed, that, in order to clear the holds of ships of the bad air contained in them, the two holes above mentioned, the fire place and ash place, be both closed up with substantial and tight iron doors, and a copper or leaden pipe, of sufficient size, be laid from the hole into the ash place, for the draught of air to come in that way to feed the fire. And thus it seems plain, from what has been already said, that there will be, from the hold, a constant discharge of the air; and consequently, that air, so discharged, must be as constantly supplied by fresh air down the hatches or such other communications as are opened into the hold. And if into this principal pipe so laid into the hold, other pipes are let in, communicating respectively either with the well or lower decks, it must follow, that part of the air consumed in feeding the fire, must be respectively drawn out of all such places to which the communication shall be so made.

AIR PUMP. See Pneumatics.

AIR SHAFTS, among miners, denote holes or apertures let down from the open air to meet the adits, and furnish fresh air. Sir Robert Murray describes a method, used in the coal mines at Liege, of working mines without air shafts. When the miners at Mendip have sunk a groove, they will not be at the charge of an air shaft till they come at ore; and for the supply of air have boxes of elm exactly closed, of about six inches in the clear, by which they carry it down about 20 fathoms. They cut a trench at a little distance from the top of the groove, covering it with turf and rods disposed to receive the pipe, which they contrive to come in sideways to their groove, four feet from the top, which carries down the air to a great depth. When they come at ore, and need an air shaft, they sink it four or five fathoms distant, according to the convenience of the breadth, and of the same fashion with the groove, to draw as well ore as air.

AIR THREADS, in natural history, a name given to the long filaments so frequently seen in autumn floating about in the air. These threads are the work of spiders, especially of that species called the long legged field spider. See Aranea.

AIR TRUNK, is a contrivance by Dr. Hales to prevent the stagnation of putrid effluvia in jails and other places where a great number of people are crowded together, in a small space. It consists only of a long square trunk, open at both ends; one of which is inserted into the ceiling of the room, the air of which is required to be kept pure; and the other extends a good way beyond the roof. The putrid effluvia, therefore, being lighter than the pure air of the atmosphere, ascend, or are forced by it, through the trunk, and carried clear away. The reason why vapours of this kind ascend more swiftly through a long trunk than a short one, is, that the pressure of fluids is always according to their different depth, without regard to the diameter of their basis, or of the vessel which contains them; and, upon this principle, a gallon of water may be made to split a strong cask. When the column of putrid effluvia is long and narrow, the difference between the column of atmosphere pressing on the upper end of the trunk, and that which presses on the lower end, is much greater than if the column of putrid effluvia was short and wide, and consequently the ascent is much swifter. One pan of a single pair of scales, which was two inches in diameter, being held within one of these trunks over the house of commons, the force of the ascending air made it rise so as to require four grains to restore the equilibrium, and this when there was no person in the house; but when it was full, no less than twelve grains were requisite to restore the equilibrium.

AIR VESSELS are spiral ducts in the leaves, &c. of plants, supposed to be analogous to the lungs of animals, in supplying the different parts of a plant with air. See Physiology of Plants.

AITONIA, so named in honour of Mr. Aiton, his majesty's gardener at Kew, a genus of the class and order monodelphia octandria. The essential character is, style 1, calyx four parted, corolla four petalled; berry dry, quadrangular, one celled, many seeded.

There is but one species, a shrub found at the Cape of Good Hope. The segments of the calyx and the petals are red; the fruit is also red and large. It must be kept in a good green house, or a moderate stove.

AJUGA, Bugle, a genus of the gymnospermia order, and didynamia class of plants; and in the natural method ranking under the 42d order, Asperifoliæ. The characters are, the calyx is a short perianthium, monophyllous and persistent; the corolla is monopetalous and grinning; the stamina consist of four erect subulated filaments; the antheræ are dimidiated; the pistillum has a four cleft ger-

men, a filiform stylus, and two slender stigmata; there is no pericarpium; the calyx converging, and containing the seeds in its bosom: the seeds are four and oblong. There are six species, the principal of which are:

1. AJUGA GENEVENSIS, with woolly leaves and hairy cups, a native of Switzerland, and of the southern parts of Europe.

2. AJUGA ORIENTALIS, with inverted flowers, is a native of the East.

3. AJUGA PYRAMIDALIS, or mountain bugle, with a square pyramidal spike and blue flowers, a native of Sweden, Germany, Switzerland and England.

4. AJUGA REPTANS, common or pasture bugle, with creeping suckers, and blue, red, or white blossoms, a native of the southern parts of Europe, and is met with in woods and moist places in many parts of Britain. The roots are astringent, and strike a black colour with vitriol of iron.

AJUTAGE, or ADJUTAGE, a sort of tube, fitted to the mouth, or aperture of the vessel, through which the water of a fountain is to be played, and by it determined into different figures. It is indeed chiefly the diversity in the ajutages that constitutes the different kinds of fountains. And hence, by having several adjutages to be supplied occasionally, one fountain comes to have the effect of many. See HYDRAULICS.

AIZOON, a genus of the pentagynia order, and icosandria class of plants, and in the natural method ranking under the 13th order, succulentæ. The characters are: the calyx is a single leaved perianthium, divided into five segments, and persistent: there is no corolla: the stamina consist of very numerous capillary filaments; the antheræ are simple: the pistillum has a five cornered germen above, with five simple styli; and the stigmata are simple: the pericarpium is a bellied, retuse, five cornered capsule, having five cells and five valves; the seeds are many and globular. There are ten species, of which,

1. AIZOON CANARIENSE, a native of the Canary islands.

2. AIZOON HISPANICUM, a native of Spain; and,

3. AIZOON PANICULATUM, a native of the Cape of Good Hope; are the principal. They may all be raised in this country in hot beds; but they are not remarkable either for beauty or any other property.

AKOND, an officer of justice in Persia, who takes cognisance of the causes of orphans and widows, of contracts and other civil concerns. He is the head of the school of law, and gives lectures to all the subaltern officers. He has his deputies in all the courts of the kingdom, who, with the second *sadra*, make all contracts.

AL, an Arabic particle prefixed to words, and signifying much the same with the English particle *the:* thus they say, alkermes, alkoran, &c. *i.e.* the kermes, the koran, &c.

ALA, in botany, is used for the hollow of a stalk, which either the leaf, or the pedicle of the leaf, makes with it; or it is that hollow turning, or sinus, placed between the stalk or branch of a plant and the leaf, whence a new offspring usually issues. Sometimes it is used for those parts of leaves otherwise called *lobes*, or *wings*.

ALABARDA, the name of a spear anciently used by the Helvetians and Germans.

ALABASTER, in natural history, a species of that genus of stones whose base is calcareous earth. It differs from marble in being combined, not with the aerial, but with sulphuric acid; therefore when mixed with any acid, no effervescence appears. It is soluble in about 500 times its weight of water at the temperature of 60. It is fusible alone in a long continued porcelain heat, or by the blow pipe. Specific gravity 1.87. Texture granular, with shining particles. In composition, and consequently in its chymical properties, it does not differ from gypsum, selenite, or plaster of Paris. The fineness and clearness of this stone render it in some measure transparent; whence it has been sometimes employed for windows. There is a church at Florence still illuminated, instead of panes of glass, by slabs of alabaster near 15 feet high, each of which forms a single window, through which the light is conveyed. The countries in Europe which abound most in alabaster are Germany, toward Coblentz; the province of Maconnois, in the neighbourhood of Cluni in France; Italy toward Rome, where that of Montaiout is particularly remarkable not only for its whiteness, but also for the size of its blocks, some of which are so large, that statues as big as the life may be easily cut out of them. A new manufacture of basso relievos, from a singular species of factitious alabaster, was some time ago established by Mr. Letapie, at the baths of St. Philip in Tuscany. The stream at these baths deposites a peculiar kind of sand, which, when collected and condensed in the cavities of any body employed to oppose its current, acquires the nature, hardness, and colour, of alabaster, and assumes the forms of those cavities in which it is thus lodged. There are three species of alabaster, *viz.*

1. ALABASTER, THE SNOW WHITE SHINING, or lygdinum of the ancients. 2. THE VARIEGATED, yellow and reddish. This species is the common alabaster of the ancients. 3. THE YELLOWISH, or phengites of Pliny, is found in Greece, Germany, France, and Derbyshire in England. The alabasters are frequently used by statuaries for small statues, vases, and columns. After being calcined and mixed with water, they may be cast in any mould like plaster of Paris. See GYPSUM and MINERALOGY.

ALÆ, in anatomy, a term applied to the lobes of the liver, the cartilages of the nostril, and sometimes to the armpits.

ALÆ, in botany, the plural of *Ala*, is used to signify those petals of leaves of papilionaceous flowers, placed between those others which are called the *vexillum* and *carina*, and which form the top and bottom of the flowers. Instances of flowers of this structure are seen in those of peas and beans, in which the top leaf or petal is the vexillum, the bottom the carina, and the side ones the alæ. Alæ is also applied to those extremely slender and membranaceous parts of some seeds which appear as wings placed on them; and likewise signifies those membranaceous expansions running along the stems of some plants, which are therefore called *alated stalks*.

ALAMODE, in commerce, a thin glossy black silk, chiefly used for women's hoods and men's mourning scarfs, commonly called mode.

ALARAF, in the Mahometan theology, the partition wall that separates heaven from hell.

ALARES, in antiquity, are supposed by some authors to have been a kind of militia or soldiers among the Romans; so called from *ala*, a wing, because of their lightness and swiftness in the combat. Others make them a

people of Pannonia; but others, with more probability, take *alares* for an adjective, or epithet, and apply it to the Roman cavalry, because placed in two wings, or *alæ*, of the army; for which reason a body of horse was called *ala*.

ALASCANI, in church history, a sect of antilutherans, whose distinguishing tenet, besides their denying baptism, is said to have been this, that the words, *This is my body*, in the institution of the eucharist, are not to be understood of the bread, but of the whole action or celebration of the supper.

ALAUDA Lark, in ornithology, a genus of birds of the order of passeres; the characters of which are, that the beak is cylindrical, subulate, and straight, bending toward the point; the mandibles are of equal size and opening downward at their base; the tongue is bifid; and the hinder claw is straighter and longer than the toe.

1. A. arvensis, the sky lark, the specific characters of which are, that the two outermost quills of its tail are white lengthwise externally, and the intermediate ones are ferruginous on the inside; the length is about seven inches. The males of this species are somewhat browner than the females: they have a black collar, and more white on the tail; their size is larger, and their aspect bolder; and they exclusively possess the faculty of singing. When the female is impregnated, she forms her nest between two clods of earth, and lines it with herbs and dry roots, being no less attentive to the concealment than to the structure of it. It sometimes builds its nest among corn and in high grass. Each female lays four or five eggs, which are grayish, with brown spots; and the period of her incubation is about 15 days. The young may be taken out of the nest when they are a fortnight old, and they are so hardy that they may be easily brought up. Some have said that she hatches three times in the year; but this must depend on the temperature of the climate. The parent is very tender of her young; and though she does not always cover them with her wings, she directs their motions, supplies their wants, and guards them from danger. The common food of the young sky larks is worms, caterpillars, ant's eggs, and even grasshoppers; and in maturity, they live chiefly on seeds, herbage, and all vegetable substances. Those birds, it is said, that are destined for singing, should be caught in October or November; and the males should, as much as possible, be selected: and when they are untractable they should be pinioned, lest they injure themselves by their violence against the roof of the cage. As they cannot cling by the toes, it is needless to place bars across their cage; but they should have clean sand at the bottom of the cage, that they may welter in it, and be relieved from the vermin which torment them.

The lark is found in all the inhabited parts of both continents, as far as the Cape of Good Hope; though Villault says that it is not found on the Gold coast; nor, according to Averroes, in Andalusia.

This bird, and the wood lark, are the only birds which sing whilst they fly. The higher it soars, the more it strains its voice, and lowers it till it quite dies away in descending. When it ascends beyond our sight, its music is distinctly heard; and its song, which is full of swells and falls, and thus delightful for its variety, commences before the earliest dawn.

In a state of freedom, the lark begins its song early in the spring, which is its season of pairing, and continues to warble during the whole of the summer.

2. A. pratensis, the tit lark, of which the specific characters are, that above it is greenish brown; its two outermost tail quills are externally white, and it has a white line on its eyebrows. This bird is of an elegant slender shape, five inches and a half long; its bill is black; the back and head of a greenish brown, spotted with black; the throat and lower part of the belly are white; the breast yellow, marked with oblong spots of black; the tail is dusky: the exterior feather is varied by a bar of white, which runs across the end and takes in the whole outmost web; the claw on the hind toe is very long, and the feet yellowish. The male has in general more yellow than the female, on the throat, breast, legs, and feet. The tit lark is found generally in meadows and low marshy grounds; and, like other larks, it makes its nest among the grass, and lays five or six eggs, which are roundish, of a dusky red colour, with many small spots. While the female hatches, the male sits on a neighbouring tree, and rises at times, singing and clapping his wings. It feeds chiefly on the worms and insects which it finds in new ploughed lands; and it will live for a long time on no other food than small seeds. Like the wood lark, it sits on trees; but it is flushed at the least noise, and shoots with a rapid flight: it has a very remarkable fine note, singing in all situations; on trees, on the ground, while it is sporting in the air, and particularly in its descent.

3. A. arborea, the wood lark of English writers, is specifically characterized by a white annular belt, encircling its head. This bird is smaller than the sky lark, and of a shorter thicker form; the colours of the plumage are paler; the first feather of the wing is shorter than the second; the hind claw is very long and somewhat bent; it perches on trees; it haunts the uncultivated tracts near copses, without penetrating the woods, whence its name; its song resembles more the warble of the nightingale, or the whistling of the black bird, than that of the sky lark; its note being less sonorous and less varied, though not less sweet; and it is heard not only in the day but in the night, both when it flies and when it sits on a bough.

This bird builds on the ground, and forms its nest on the outside with moss, and on the inside with dried bents, lined with a few hairs, and conceals it with a turf; and the situation it selects is ground where the grass is rank, or become brown. It lays four or five eggs, which are dusky and blotched with deep brown; its fecundity is inferior to that of the sky lark, and its numbers are not so great: it breeds earlier, since its young are sometimes flown in the middle of March, and therefore they pair in February, at which time, and not before, they part with their last year's brood; whereas, the common lark does not hatch before the month of May. This is a very tender and delicate bird; so that it is impossible to rear the young taken out of the nest; but this is the case only in England and such cold climates, for in Italy they are removed from the nest, and reared at first like the nightingale, and afterward fed upon panic and millet. The wood lark feeds on beetles, caterpillars, and seeds: its tongue is forked; its stomach muscular and fleshy; and it has no craw, but a moderate dilatation of the lower part of the œsophagus; and its cæca

are very small. It lives ten or twelve years. The males are distinguished from the females by their larger size; the crown of the head is also of a darker colour, and the hind nail longer; its breast is more spotted, and its great wing quills edged with olive, which in the female is gray. The wood lark mounts high, warbling its notes, and hovering in the air; it flies in flocks during the winter colds; it is found in Sweden and Italy, and is probably dispersed through the intervening countries, and consequently over the greatest part of Europe. It is also found in Siberia, as far as Kamtschatka, and in the island of Madeira.

4. A. campestris, the meadow lark, is rather larger than the tit lark, being six inches and a half in length. Its specific characters are, that its tail quills are brown; the lower half, except two intermediate quills, white; the throat and breast yellow. According to Willughby, the meadow lark differs from the other larks by the blackness of its bill and feet; he adds, that its bill is slender, straight, and pointed, and the corners of its mouth edged with yellow; that it has not, like the wood lark, the first quills of the wings shorter than the succeeding; and that in the male the wings are rather darker than in the female. Though the males are hardly to be distinguished from the females by their external appearance, yet if another male is presented, shut up in a cage, they will instantly attack it as an enemy or a rival. This bird has a slenderer body than the sky lark, and is distinguished from it by the shake of its tail, like that of the wagtail and tit lark. It inhabits heaths and uncultivated tracts, and frequently the oat stubble, after the corn is reaped, where birds of this species gather together in numerous flocks. In spring, the male perches to discover or woo his mate, and sometimes he mounts into the air, singing with all his might, and then descends quickly to pair on the ground. When a person approaches the nest, the female betrays her fears by her cries; whereas, other larks are silent and unmoved, when danger is apprehended. They make their nest close to the ground, sometimes in furze bushes, and form it of moss, lined with straw and horse hair.

5. A. trivialis, is distinguished by brown tail quills, the outermost half white, the second white at its wedgelike tip, with a double whitish line on the wings. The German epithet *piep*, and the English *pippit*, formed from the Latin *pipio*, which signifies to utter a feeble cry like chickens, alludes to the sibilous notes of this bird. Its cry, especially in winter, is like that of the grasshopper, but stronger and shriller, and it utters this, both when perched on the tallest branches among the bushes, and when it is on the wing. Its tones are soft, harmonious, and clear. This little bird builds its nest in solitary spots, concealed under a turf, and its young are frequently a prey to the adders. It lays five eggs, of a light grass green colour, thinly sprinkled with deeper coloured specks. The grasshopper larks appear in England about the middle of September, and great numbers of them are caught in the environs of London.

6. A. cristata, is distinguished by black tail quills, the two outermost white at their exterior edge, its head crested, and its feet black. Its length is about six inches and three quarters. It lives in the meadows and fields, on the sides of ditches, and the backs of furrows: it is often seen at the margin of water, and on the high roads, rarely in the skirts of woods, perched on a tree, and sometimes on the tops of houses, and of abbeys, &c. This lark, though not so common as the sky lark, is found in most parts of Europe, in Italy, France, Germany, Poland, Denmark, Russia, Scotland, and does not change its abode in winter. The song of the males is loud, and yet mellow and pleasant; and their warbling is usually accompanied with a quivering of the wings.

The crested lark is the only one that may be instructed; in a month it learns many airs perfectly, which it repeats without confusion, and retains nothing of its native warble; and in these particulars it is superior to the canary.

The other species are, the alauda rufa, capensis, calandra, alpestris, magna, minor, italica, ludoviciana, rubra, mosellana, malabarica, gingica, tartarica, mutabilis, nemorosa, undata, senegalensis, testacea, lusitana, africana, cinerea, Novæ Zeelandiæ, mongolica, sibirica, flava, obscura, most of them foreign birds. In all, 33 species.

ALBARIUM OPUS, in the ancient building, the incrustation or covering of the roofs of houses with white plaster, made of mere lime. This is otherwise called *opus album*. It differs from *tectorium*, which is a common name given to all roofing or ceiling, including even that formed of lime and sand, or lime and marble; whereas albarium was restrained to that made of lime alone.

ALBATROSSE. See DIOMEDEA.

ALBE, a small piece of money, current in Germany, worth only a French sol and seven deniers.

ALBERNUO, a kind of camblet, brought from the Levant by the way of Marseilles.

ALBERTUS, a gold coin, worth about 14 French livres: it was coined during the administration of Albertus, archduke of Austria.

ALBIGENSES, in church history, a party of reformers about Tonlouse and the Albigeois in Languedoc, who sprung up in the twelfth century, and distinguished themselves by their opposition to the discipline and ceremonies of the church of Rome. This sect had their name, it is supposed, either because there were great numbers of them in the diocese of Albi, or because they were condemned by a council held in that city. In fact it does not appear that they were known by this name before the holding of that council. The albigenses were also called *albiani*, *albigesei*, *albii*, and *albanenses*, though some distinguish these last from them. The albigenses, by the truth of their doctrines, and their vigour and energy in propagating them, became so formidable, that the papists agreed upon a holy league or crusade against them. They were at first supported by Raimond, count of Toulouse. Pope Innocent III. desirous to put a stop to their progress, sent a legate into their country, which failing, he stirred up Philip Augustus, king of France, and the other princes and great men of the kingdom, to make war upon them. Upon this, the count of Toulouse, who had supported them, made his submission to the pope, and went over to the Catholics; but soon after, finding himself plundered by the crusaders, he declared war against them, and was joined by the king of Arragon. His army was defeated at the siege of Muret, where he himself was killed, and the defeat followed by the surrender of the city of Toulouse, and the conquest of the greatest part of Languedoc and Provence. His son Raimond succeeded him; who agreed with the king and the pope to establish the

inquisition in his estates, and to extirpate the Albigenses. In an assembly held at Milan, the archbishop of Toulouse drew up articles; agreeable to which the count made a most ample declaration against them, which he published at Toulouse in 1253. From this time the Albigenses dwindled by little and little, till the times of the reformation; when such of them as were left fell in with the Vaudois, and became conformable to the doctrine of Zuinglius and the discipline of Geneva.

ALBIGENSES is also a name sometimes given to the followers of Peter Vaud, or Waldo; and hence synonymous with Waldenses, or poor men of Lyons. In this sense the word is applied by Camerarius, Thuanus, and several other writers. The reason seems to be, that the two parties agreed in their opposition to the papal innovations and encroachments, though in many other respects different. The bishop of Meaux labours hard to support a distinction between the two sects, alleging, that the Albigenses were heretics and Manichees; whereas the Waldenses were only schismatics, not heretics, being sound as to articles of faith, and only separating from the church of Rome on account of forms and discipline. Dr. Allix endeavours to set aside the distinction; and shows, that both of them held the same opinions, and were equally condemned and held for heretics; and this not for points of faith, but for declaiming against the papal tyranny and idolatry, and holding the pope to be the antichrist; which last, according to the bishop of Meaux, constitutes little less than Manicheism. In this sense the Lollards and Wickliffites in England were not only Albigenses but Manichees.

ALBINOS, the name by which the Portuguese call the white moors, who are looked upon by the negroes as monsters. They at a distance might be taken for Europeans; but, upon a near inspection, their white colour appears like that of persons affected with a leprosy. In Saussure's Voyages dans les Alpes, is the following account of two boys, at Chamouni, who have been called albinos: "The elder, who was at the end of the year 1785 about twenty or twenty-one years of age, had a dull look, with lips somewhat thick, but nothing else in his features to distinguish him from other people. The other, who is two years younger, is rather a more agreeable figure: he is gay and sprightly, and seems not to want wit. But their eyes are not blue; the iris is of a very distinct rose colour: the pupil too, when viewed in the light, seems decidedly red: which seems to demonstrate, that the interior membranes are deprived of the uvea, and of that black mucous matter that should line them. Their hair, their eyebrows, and eye lashes, the down upon their skin, were all, in their infancy, of the most perfect milk white colour, and very fine; but their hair is now of a reddish cast, and has grown pretty strong. I am therefore of opinion that we may consider these two lads as true albinos: for if they have not the thick lips and flat noses of the white negroes, it is because they are albinos of Europe, not of Africa. This infirmity affects the eyes, the complexion, and the colour of the hair; it even diminishes the strength, but does not alter the conformation of the features. Besides, there are certainly in this malady various degrees: some may have less strength, and be less able to endure the light: but these circumstances in those of Chamouni are marked with characters sufficiently strong to entitle them to the unhappy advantage of being classed with that variety of the human species denominated albinos."

ALBORAK, amongst the Mahometan writers, the beast on which Mahomet rode in his journies to heaven. The Arab commentators give many fables concerning this extraordinary vehicle. It is represented as of an intermediate shape and size between an ass and a mule. A place, it seems, was secured for it in paradise at the intercession of Mahomet; which, however, was in some measure extorted from the prophet by Alborak's refusing to let him mount him when the angel Gabriel was come to conduct him to heaven.

ALBUCA, a genus of the hexandria monogynia class and order. The essential character is, corolla six petalled, inner ones difform, stamina three of the six castrated stigma, surrounded by six carps. There are eight species, rather tender, but may be kept in winter in a garden frame.

ALBUGINEA, in anatomy, the outermost coat or tegument of the eye, otherwise called *adnata* and *conjunctiva*.

ALBUGO, or LEUCOMA, is defined by physicians to be a distemper occasioned by a white opaque spot growing on the corner of the eye, and obstructing vision. See MEDICINE.

ALBULA, in ichthyology, a genus of fishes of the truttaceous kind, having no teeth. The principal species are,

1. Albula indica, a small fish resembling a herring, caught about the shores of the East Indies, and called by the Dutch the wit fish.

2. Albula nobilis, a truttaceous fish caught in great plenty in the lakes of Germany and other places.

ALBULA, in natural history, mineral waters of an aluminous kind; hence endowed with an astringent quality, and of use in wounds.

ALBUMEN. The eggs of fowls contain two very different substances: a yellow oily like matter, called the *yolk*, and a colourless glossy viscid liquid, distinguished by the name of *white*. This last is the substance which chymists have agreed to denominate albumen. The white of an egg, however, is not pure albumen. It contains, combined with it, some soda and some sulphur: but as albumen is never found except combined with these bodies, and as no method is known of separating it without at the same time altering the properties of the albumen, chymists are obliged to examine it while in combination with these bodies.

Albumen dissolves readily in water, and the solution has the property of giving a green colour to vegetable blues, in consequence of the soda which it contains. When albumen is heated to the temperature of 165°, it coagulates into a white solid mass; the consistency of which, when other things are equal, depends, in some measure, on the time during which the heat was applied. The coagulated mass has precisely the same weight that it had while fluid. This property of coagulating when heated is characteristic of albumen, and distinguishes it from other bodies.

The taste of coagulated albumen is quite different from that of liquid albumen; its appearance, too, and its properties, are entirely changed; for it is no longer soluble, as before, either in hot or in cold water.

The coagulation of albumen takes place even though air is completely excluded; and even when air is present, there is no absorption of it, nor does albumen in coagulating change its volume. Acids have the property of coagulating albumen, as Scheele ascertained. Alcohol also produces, in some measure, the same effect. Heat, then, acids and alcohol, are the agents which may be employed to coagulate albumen.

Scheele and Fourcroy have ascribed the coagulation of albumen to the addition of a new substance. According to Scheele, caloric is the substance which is added. Fourcroy, on the contrary, affirms that it is oxygen.

Albumen then is capable of existing in two states; the one before it has been coagulated, and the other after it has undergone coagulation. Its properties are very different in each. It will be proper, therefore, to consider them separately.

1. Albumen, in its natural state or uncoagulated, is a glary liquid, having little taste, and no smell. When dried spontaneously, or in a low heat, it becomes a brittle, transparent, glassy like substance, which, when spread thin upon plain surfaces, forms a varnish, and is accordingly employed by bookbinders for that purpose. When thus dried, it has a considerable resemblance to gum-arabic, to which also its taste is similar. The white of an egg loses about four 5ths of its weight in drying. It is still soluble in water, and forms the same glary liquid as before. Uncoagulated albumen soon putrefies unless it is dried; in which state it does not undergo any change.

2. When albumen is coagulated either by heat, alcohol, or acids, it is an opaque substance of a pearl white colour, tough, and of a sweetish mucilaginous taste. It is no longer soluble in water, and is not nearly so susceptible of decomposition as uncoagulated albumen. Mr. Hatchet kept it for a month under water, and yet it did not become putrid. It is to the experiments of this ingenious chymist that we are indebted for almost every thing at present known relative to coagulated albumen. By drying it in the temperature of 212°, he converted it into a brittle, hard, yellow substance, semi-transparent like horn.

These properties indicate sufficiently that coagulated albumen is a very different substance from uncoagulated albumen. During the coagulation its component parts must arrange themselves differently.

From the effects of nitric acid on albumen and its products, when subjected to destructive distillation, it has been concluded that it consists of carbon, hydrogen, azote, and oxygen, in unknown proportions. As it yields more azotic gas to nitric acid, it has been considered as containing more of that principle than gelatine. It is obvious, however, that it does not differ much from that body, as nitric acid spontaneously converts it into gelatine. Albumen forms the membranous parts of many shells, sponges, &c. It is, in short, one of the most important and general animal substances.

The property which albumen has of being coagulated by heat renders it a very useful substance for clarifying fluids. See Thompson's Chymistry.

Albumen, vegetable. This substance was discovered by Fourcroy, who observed that the clarification of the expressed juices of antiscorbutic plants was effected by the spontaneous coagulation of their colouring matter, at the temperature of boiling water, on which account he was led to examine whether this property did not depend on the presence of albumen. He obtained the juice of two pounds of young cresses, and filtered it while cold through blotting paper, and thus separated the grosser parts of the colouring fecula; the liquor was still of a bright green, and upon being exposed in a broad shallow vessel to the air at the temperature of 80° Fahrenheit, in two hours it became turbid, and deposited green matter, becoming itself almost colourless; in this state it was exposed to the heat of boiling water, and in a few minutes there separated a quantity of whitish flocculent matter. Another portion of the same liquor exposed to the air, deposited, at the end of two days, a similar coagulum; and the same effect was produced on a third portion by the addition of sulphuric acid. This substance exhibited all the properties of animal albumen.

Albumen has since been found in the roots of various vegetables; also in wheat, and the farinaceous seeds; and in general in all the green and succulent plants. The acid pulp of fruits are totally destitute of this substance, but they abound with jelly; and it is supposed that, in all these cases, there is a conversion of albumen into jelly, by the gradual evolution of the acid, and fixation of oxygen.

ALBURNUM, the soft white substance found in trees between the liber, or inner bark, and the true wood, and which, in process of time, is itself converted into that substance. It is found in the largest quantities in trees which are vigorous. In an oak of six inches in diameter this substance is nearly equal in bulk to the wood. In a trunk of one foot diameter, it is as one to three and a half; of two and a half feet diameter, as one to four and a half, &c. but these proportions vary according to the health and constitution of the trees. The alburnum is frequently gnawed in pieces by insects, which lodge in this substance, and are nourished from it.

ALCA, or Auk, in ornithology, a genus of the order of anseres. The beak of this genus is without teeth, short, convex, compressed, and frequently furrowed transversely: the inferior mandible is gibbous near the base; the feet have generally three toes. There are 12 species of the alca, of which the most remarkable are,

1. Alca alle, the little auk, or black and white diver, with a smooth conical bill, a white streak on the belly and wings, and black feet. The size of this species exceeds not that of a blackbird. It is not very common in England. It seems to be most plentiful toward the north, being met with in various parts as far as Spitzbergen. It is common in Greenland, in company with the black billed species; feeds on the same food; and lays two bluish eggs, larger than those of a pigeon. It flies quick, and dives well; and is always dipping its bill into the water, while swimming or at rest on the water. It grows fat in the stormy season, from the waves bringing plenty of crabs and small fish within its reach: but from its size it is less sought after than the others. In Greenland it is called the ice bird, being the harbinger of ice. This species is sometimes seen of a pure white.

2. A. Arctica, known in England by the name of *puffin*. See Plate Nat. Hist. fig. 8. These birds are found upon several of the rocky coasts in England, in Ireland, North Britain, Iceland, and Greenland. They frequent Carolina in America during winter, and have been met with in Sandwich sound, where the natives or-

nament the fore parts and collar of their seal skin jacket with the beaks of them. On the coast of Kamtschatka, and the Kurile islands, the inhabitants wear the bills of the artica about their necks, and their priests put them on with a proper ceremony, in order to procure good fortune. They arrive at their breeding places here about the first week in May, and endeavour to dislodge the rabbits to save the trouble of making holes for themselves. The female lays but one egg, and the young are hatched in the beginning of July, and about the middle of August they take their flight. The young that are late hatched, become the prey of falcons, &c. Notwithstanding their neglect of the young at this time, on every other occasion they are very attentive to them. They will suffer themselves to be taken by the hand, and use every means of defence in their power to save them; and if held by the wings, will tear their bodies, as if actuated by despair, and when released, instead of flying away, will hurry again into the burrow to their young.

3. Alca cirrhata, so called by Dr. Pallas, or tufted auk, is somewhat bigger than the common puffin, and the colours much the same: the bill is an inch and three quarters in length, the same in depth at the base, and crossed with three furrows: over each eye arises a tuft of feathers four inches in length, which falls elegantly on each side of the neck, reaching almost to the back; and white as far as they are attached to the head, but afterward of a fine buff yellow; the legs are of a bright red; the claws black. The female is principally distinguished by having the bill crossed only with two furrows instead of three. This species inhabits the shores of Kamtschatka, the Kurile islands, and those intervening between Kamtschatka and America. In manners it greatly resembles the puffin; living all day at sea, but at no great distance from the rocks; it comes on shore at night; burrows a yard deep under ground, and makes a nest with feathers and sea plants; is monogamous, and lodges there the whole night with its mate. It lays one white egg in the end of May or beginning of June, which alone is thought fit to be eaten, the flesh of the bird itself being insipid and hard. It feeds on crabs, shrimps, and shell fish, which last it forces from the rocks with its strong bill.

4. Alca impennis, the northern penguin, or great auk, with a compressed bill, furrowed on each side, and an oval spot on each side of the eyes. According to Mr. Martin, this bird breeds on the isle of St. Kilda; appearing there the beginning of May, and retiring the middle of June. It lays one egg, which is six inches long, of a white colour; some are irregularly marked with purplish lines crossing each other: if the egg is taken away, it will not lay another that season. The length of this bird, to the end of its toes, is three feet; but its wings are so small, as to be useless for flight; the length, from the tip of the longest quill feathers to the first joint, being only four inches and a quarter. This bird is observed by seamen never to wander beyond soundings; and according to its appearance they direct their measures, being then assured that land is not very remote. It walks ill; but dives well, and is taken in the manner used for the razor bill and puffin. The skin between the jaws is blown into a bladder, and used for the darts of the Greenlanders, as is also that of some other birds.

5. Alca pica, or black billed auk, has the bill of the same form with the torda, but is entirely black. Mr. Pennant observes, that it is sometimes found on our coasts; but, according to Mr. Latham, it is in the winter season only, when the common sort has quitted them. They are said to be met with on the coast of Candia, and other parts of the Mediterranean.

6. Alca psittacula, or perroquet auk of Dr. Pallas, is about the size of the little auk. The bill is much compressed on the sides, in shape convex both above and below, and of a bright red colour: from the remote corner of each eye is a very slender tuft of fine white feathers, hanging down the neck. This species is found at Kamtschatka, in the isles toward Japan, and on the western shores of America. They are sometimes seen in flocks, but seldom far from land, except when driven by storms. During night they harbour in the crevices of rocks. About the middle of June they lay an egg, almost the size of a hen's, of a dirty white or yellowish colour, spotted with brown, upon the bare rock, or sand, for they make no nest. Like most of the tribe, they are stupid birds, as is evinced by the method of catching them. One of the natives places himself under a loose garment of fur, of a particular make, with large open sleeves, among the rocks at evening; when the birds, returning to their lodging places at dusk, run under the skirts, and up the arm holes, for shelter during the night, and thus become an easy prey. Their stupidity likewise appears from their flying aboard ships, mistaking them for roosting places.

7. Alca torda, or the razor bill, with four furrows on the bill, and a white line on each side running from the bill to the eyes. These birds, in company with the guillemot, appear in our seas the beginning of February, but do not settle on their breeding places till they begin to lay, about the beginning of May. They inhabit the ledges of the highest rocks that impend over the sea, where they form a grotesque appearance; sitting close together, and in rows one above another. They properly lay but one egg apiece, of an extraordinary size for the bulk of the bird, being three inches long; it is either white or of a pale sea green, irregularly spotted with black. If this egg is destroyed, both the auk and the guillemot will lay another: if that is taken, then a third: they make no nest, depositing their egg on the bare rock; and though such multitudes lay contiguous, by a wonderful instinct each distinguishes its own. What is also matter of great amazement, they fix their egg on the smooth rock with so exact a balance, as to secure it from rolling off; yet should it be removed, and then attempted to be replaced by the human hand, it is extremely difficult, if not impossible, to find its former equilibrium. According to Mr. Latham, it is by means of a cement that the bird fixes its egg.

ALCAIC, in ancient poetry, a denomination given to several kinds of verse, from Alcæus, their inventor. 1. The first kind consists of five feet, *viz.* a spondee, or iambic; an iambic; a cæsura, and two dactyles; such is the following verse of Horace:

Eheu! | fuga | ces, | Postume, | Postume,
Labnn tur an ni! | nec pie | tas moram.

2. The second kind consists of two dactyles and two trochees: as,

Afferet, | indom | tæque | morti.

3. Besides these two, which are called dactylic Alcaics, there is another styled simply Alcaic; consisting of an epitrite, two choriambus, and a bacchius: the following is of this species.

Cur timet fla | vum Tiberim | tangere, cur | olivum?

ALCAID, Alcayde, or Alcalde, in the polity of the Moors, Spaniards, and Portuguese, a magistrate, or officer of justice, answering nearly to the office of the British justice of peace. The alcaid among the Moors is invested with the supreme jurisdiction, both in civil and criminal cases.

ALCANNA, in commerce, a cosmetic powder prepared from the leaves of the Egyptian privet. It is much used by the Turkish women to give a golden colour to their nails and hair. There is also an oil extracted from the berries of alcanna, and used in medicine as a quiescent.

ALCANTARA, *the knights of*, a military order of Spain, which took its name from the above mentioned city. They make a very considerable figure in the history of the expeditions against the Moors. After the expulsion of the Moors, and the taking of Granada, the sovereignty of the order of Alcantara and that of Calatrava was settled in the crown of Castile by Ferdinand and Isabella. In 1540 the knights of Alcantara sued for leave to marry, which was granted them.

ALCAVALA, in the Spanish finances, was at first a tax of 10 per cent. afterward of 14 per cent. but is at present of only 6 per cent. upon the sale of every sort of property, whether moveable or immoveable; and it is repeated every time the property is sold. The levying of this tax requires a multitude of revenue officers sufficient to guard the transportation of goods, not only from one province to another, but from one shop to another. It is to the alcavala, accordingly, that Ulloa imputes the ruin of the manufactures of Spain.

ALCEA, the Hollyhock: a genus of the polyandria order, belonging to the monodelphia class of plants; and in the natural method ranking under the 37th order, columniferæ. The characters are: the calyx is a double perianthium, monophyllous and persistent; the exterior one six cleft, the interior half five cleft: the corolla consists of five petals, coalesced at the base, heart shaped inversely, and expanding: the stamina consist of numerous filaments, coalesced below into a five cornered cylinder, loose above, and inserted into the corolla; the antheræ are kidney shaped: the pistillum has a roundish germen; a short cylindric stylus; and numerous bristly stigmata the length of the stylus: the pericarpium consists of many arilli, jointed into a verticillum about a columnar depressed receptacle; the seeds are solitary, reniform, and depressed. There are three species, the alcea ficifolia, rosea, and africana.

ALCEDO, or Kingfisher, in ornithology, a genus of the order of picæ. The alcedo has a long, straight, thick, triangular bill; with a fleshy, plain, short, flat tongue. Of this genus there are many species, with one or other of which almost every part of the world is furnished. Most of them frequent rivers, and live on fish, the singularity of catching which is admirable: sometimes hovering over the water, where a shoal of small fishes is seen playing near the surface; at other times waiting with attention, on some low branch hanging over the water, for the approach of a single fish which is so unlucky as to swim that way; in either case dropping like a stone, or rather darting with rapidity on its prey; when, seizing it crosswise in its bill, it retires to a resting place to feast on it; which it does piecemeal, bones and all, without reserve, afterward bringing up the indigestible parts in pellets, like birds of prey. The wings of most of the genus are very short; yet the birds fly rapidly and with great strength. It may be remarked, that throughout this genus, blue, in different shades, is the most predominant colour. There are above 30 species of this genus, of which the following are the most remarkable, *viz.* See Plate Nat. Hist. fig. 9 and 10.

1. Alcedo galbula, or green jacamar, is about the size of a lark. The bill is black, of a square form, a little incurvated and sharp at the point; the plumage, in general, in the upper part of the body, is of a most brilliant green, glossed with copper and gold in different lights. This species is found both in Guiana and Brazil, in the moist woods, which it prefers to the more dry spots, for the sake of insects, on which it feeds. Though these birds are solitary, yet they are far from scarce, as many may be met with. They are said to have a short and agreeable note.

2. Alcedo ispida, or common kingfisher, is not much larger than a swallow; its shape is clumsy; the bill disproportionably long, it is two inches from the base to the tip, the upper chap black, and the lower yellow. But the colours of this bird atone for its inelegant form: the crown of the head and the coverts of the wings are of a deep blackish green, spotted with bright azure; the back and tail are of the most resplendent azure; the whole under side of the body is orange coloured; a broad mark of the same passes from the bill beyond the eyes. From the diminutive size, the slender short legs, and the beautiful colours of this bird, no person would be led to suppose it one of the most rapacious little animals that skims the deep. M. D'Aubenton has kept these birds for several months, by means of small fish put into basins of water, on which they have fed; for on experiment they have refused all other kinds of nourishment.

3. Alcedo Paradisea, or paradise jacamar, is of the same size with the former, and has a similar bill; the throat, fore part of the neck, and under wing coverts, are white; the rest of the plumage is of a deep dull green, in some lights appearing almost black, in others with a slight gloss of violet and copper bronze. It inhabits Surinam; and like the galbula it feeds on insects; and sometimes frequents open places. It flies further at a time, and perches on the tops of trees: it is frequently found with a companion, not being quite so solitary a bird as the other.

4. Alcedo rudis, or Egyptian kingfisher, is the size of the Royston crow. The bill is blackish, more than half an inch broad at the base, and two inches in length; the head, shoulders, and back, are brown, marked with oblong ferruginous spots; the throat is of a ferruginous white; the belly and thighs are whitish, marked with longitudinal broadish cinereous spots; the upper tail coverts quite white; the quills spotted with white on the inner webs, chiefly at the tips; the tail is ash coloured;

the legs are of a pale green; and the claws blackish. It inhabits lower Egypt, about Cairo; builds in sycamore and date trees; and feeds on frogs, insects, and small fish, which last it meets with in the fields when they are overflowed.

5. ALCEDO TAPARARA of Buffon is about the size of a starling: the hind part of the neck, the back, and scapulars, are of an elegant blue; the rump, and upper tail coverts bright beryl blue; the under parts of the body are white; the wing coverts blue; and the legs red. Inhabits Cayenne and Guiana.

6. ALCEDO TORQUATA, or cinereous kingfisher, is about the size of a magpie. The bill is three inches and a half long, and brown; the head is crested; the upper parts of the head and body are bluish ash; the under parts chesnut; the throat is whitish, descending down the neck, and passing behind like a collar, ending toward the back in a point; the under tail coverts are of a pale fulvous, transversely striated with black; lesser wing coverts varied with bluish, ash, black, and yellowish. It inhabits Martinico and Mexico.

ALCHEMILLA, or LADIES MANTLE, a genus of the monogynia order, and tetandria class of plant; and in the natural method ranking under the 35th order, Senticosæ. The essential character is calyx 8 cleft, corolla none, seed one. There are 4 species, the principal are:

1. ALCHEMILLA ALPINA, or cinque foil ladies mantle. It is a native of the mountainous parts of Europe. Goats and cows eat it; horses, sheep, and swine, refuse it.

2. ALCHEMILLA MINOR, or least ladies mantle. It grows naturally in Sweden, Lapland, and other cold countries.

3. ALCHEMILLA VULGARIS, or common ladies mantle, with leaves plaited like a fan, and yellowish green blossoms. It grows naturally in pasture lands in this as in most other countries in Europe. The leaves discover to the taste a moderate astringency; and were formerly much esteemed in some female weaknesses, and in fluxes of the body. They are now rarely made use of, though both the leaves and roots might possibly be of service in cases where mild astringents are required.

ALCHORNIA, a genus of the dioecia monodelphia class and order. The essential character is, male, calyx three, five leaved; corolla none: female, calyx five toothed, corolla none, styli two parted, capsule berried, decorous. There is one species of which little seems to be known in this country.

ALCHYMY, from *al*, the, Arab. and Χημια, chymistry, that obsolete branch of chymistry which had for its principal objects the transmutation of metals into gold; the panacea, or universal remedy; an alkahest, or universal menstruum; an universal ferment; and many other things equally ridiculous.

ALCOHOL, or ALKOOL, in chymistry, is used for any highly rectified spirit. Alcohol is extremely light and inflammable, is a strong antiseptic, and therefore employed to preserve animal substances. See CHYMISTRY.

ALCOHOL, ardent spirit. The term alcohol is applied by modern chymists to the purely spirituous part of all liquors that have undergone the vinous fermentation. It is certain, that the method of procuring ardent spirits by distillation was known in the dark ages; and it is more than probable that it was practised in the north of Europe much earlier.

Ardent spirits, such as brandy, for instance, rum and whisky, consist almost entirely of three ingredients, water, alcohol, or spirit of wine, to which they owe their strength, and a small quantity of a peculiar oil, from which they derive their flavour.

When these spirituous liquors are distilled in a water bath, the first portion that comes over is a fine light transparent liquid, known in commerce by the name of rectified spirits, and commonly sold under the denomination of alcohol or spirit of wine. It is not, however, as strong as possible, still containing a considerable portion of water. This water may be separated, and the alcohol obtained as pure as possible, by the following process: Saturate the spirit with a quantity of carbonate of potash, which has just immediately before been exposed for about half an hour in a crucible to a red heat, in order to deprive it of moisture. Carbonate of potash in this state has a strong attraction for water; it accordingly combines with the water of the spirit; and the solution of carbonate of potash thus formed sinks to the bottom of the vessel, and the alcohol, which is lighter, swims over it, and may easily be decanted off; or, what is perhaps better, the solution of potash may be drawn off from below it by means of a stop cock placed at the bottom of the vessel. The alcohol, thus obtained, contains a little pure potash dissolved, which may be separated by distilling it in a water bath with a very small heat. The alcohol passes over, and leaves the potash behind. It is proper not to distill to dryness.

Alcohol is a transparent liquor, colourless like water, of a pleasant smell, and a strong, penetrating, agreeable taste. When swallowed it produces intoxication.

It is exceedingly fluid, and has never been frozen, though it has been exposed to a cold so great that the thermometer stood at —69°.

Its specific gravity, when pure, is only 0.800; but it is seldom obtained so low. The specific gravity of alcohol, as highly rectified as possible, is 0.820; that of the alcohol of commerce is seldom less than 0.8371. It is almost unnecessary to remark, that the diminution of specific gravity is always proportional to the purity of the alcohol.

Alcohol is exceedingly volatile, boiling at the temperature of 176°; in which heat it assumes the form of an elastic fluid, capable of resisting the pressure of the atmosphere, but which condenses again into alcohol when that temperature is reduced. In a vacuum it boils at 56°, and exhibits the same phenomena; so that was it not for the pressure of the atmosphere, alcohol would always exist in the form of an elastic fluid, as transparent and invisible as common air. It is exceedingly combustible; and when set on fire, it burns all away with a blue flame, without leaving any residuum. Boerhaave observed, that when the vapour which escapes during this combustion is collected in proper vessels, it is found to consist of nothing but water. Junker had made the same remark; and Dr. Black suspected, from his own observations, that the quantity of water obtained, if properly collected, exceeded the weight of the alcohol consumed. This observation was confirmed by Lavoisier; who found that the water produced during the combustion of alcohol exceeded the alcohol consumed by about one-seventh part.

Different opinions were entertained by chymists about the nature of alcohol; but Lavoisier was the first who at-

tempted to analyze it. From his experiments it follows, that 76.7083 grains of alcohol, consumed during the combustion, were composed of

22.840	carbon
6.030	hydrogen
47.830	water
76.7	

Such were the consequences which Mr. Lavoisier drew from his analysis. He acknowledged, however, that there were two sources of uncertainty, which rendered his conclusions not altogether to be depended upon. The first was, that he had no method of determining the quantity of alcohol consumed, except by the difference of weight in the lamp before and after combustion; and that therefore a quantity might have evaporated without combustion, which, however, would be taken into the sum of the alcohol consumed. But this error could not have been great; for if a considerable quantity of alcohol had existed in the state of vapour in the vessel, an explosion would certainly have taken place. The other source of error was, that the quantity of water was not known by actual weight, but by calculation.

That alcohol contains oxygen, has been proved by a very ingenious set of experiments performed by Mess'rs Fourcroy and Vauquelin. When equal parts of it and sulphuric acid are mixed together, the sulphuric acid suffers no change; but the alcohol is decomposed, being partly converted into water and partly into ether. Now it is evident that the alcohol could not have been converted into water unless it had contained oxygen.

When alcohol, in the state of vapour, is made to pass through a red hot porcelain tube, it is decomposed completely. Carbureted hydrogen gas and carbonic acid gas are disengaged; water passes into the receiver, and on its inner surface are deposited a number of small brilliant crystals, which Vauquelin ascertained to be a concrete volatile oil. The inside of the volatile tube is coated with charcoal in the state of a fine black. This experiment was first made by Priestley; but it was afterward repeated with more care, and the nature of the products ascertained by the Dutch chymists.

Alcohol has a strong affinity for water, and is miscible with it in every proportion. The specific gravity varies according to the proportion of the two liquids combined; but, as happens in almost all combinations, the specific gravity is always greater than the mean of the two liquids; consequently there is a mutual penetration: and as this penetration or condensation varies also with the proportions, it is evident that the specific gravity of different mixtures of alcohol and water can only be ascertained by experiment. As the spirituous liquors of commerce are merely mixtures of alcohol and water in different proportions, and as their strength can only be ascertained with precision by means of their specific gravity, it becomes a point of very great importance to determine with precision the proportion of alcohol contained in a spirit of a given specific gravity: and as the specific gravity varies with the temperature, it is necessary to make an allowance for that likewise.

The importance of this object, both for the purposes of revenue and commerce, induced the British government to employ sir Charles Blagden to institute a very minute and accurate series of experiments. An account of these was published by Blagden in the Philosophical Transactions for 1790; and a set of tables, exhibiting the result of them, was drawn up by Mr. Gilpin, who had performed the experiments, and published in the Philosophical Transactions for 1794.

The following little table constructed from Dr. Thomson's experiments will enable the reader to ascertain the proportion of real alcohol and water in mixtures. Suppose alcohol at 0.800 to be pure; then alcohol of 0.813 is composed of 100 alcohol + 2 water.

0.813	100 + 4
0.825	100 + 7.53 or 93 + 7.

Alcohol has no action upon sulphur while solid; but when these two bodies are brought together both in the state of vapour, they combine and form a reddish sulphuret, which exhales the odour of sulphurated hydrogen gas. This compound contains about 60 parts of alcohol and one part of sulphur. The sulphur is precipitated by water. Alcohol dissolves also a little phosphorus when assisted by heat. This phosphorized alcohol exhales the odour of phosphurated hydrogen gas. When a little of it is dropped into a glass of water, a flame instantly makes its appearance, and waves beautifully on the surface of the water. This phenomenon, which is occasioned by the emission of a little phosphurated hydrogen gas, can only be observed when the experiment is performed in a dark room.

Alcohol has no action upon charcoal, hydrogen gas, azotic gas, the metals, nor upon any of the metallic oxides.

Alcohol dissolves the fixed alkalies very readily, and forms with them a reddish coloured acrid solution. It is from this solution only that these alkalies can be obtained in a state of purity. When heat is applied to it, the alcohol is partly decomposed; but the nature of the products has not been accurately ascertained. Ammonia also combines with alcohol with the assistance of heat: but at a temperature somewhat below the boiling point of alcohol, the ammonia flies off in the state of gas, carrying with it, however, a little alcohol in solution.

None of the earths are acted upon by alcohol. It absorbs about its own weight of nitrous gas, which cannot afterward be expelled by heat.

Sulphuric acid, nitric acid, and oxymuriatic acid, decompose alcohol; but all the other acids are soluble in it, except the metallic acids, phosphoric acid, and perhaps also prussic acid.

Alcohol is capable of dissolving a great many saline bodies. A considerable number of these, with the quantities soluble, is exhibited in the following tables:

1. *Substances dissolved in large quantities.*

Names of the substances.	Temperature.	240 parts of alcohol dissolve
Oxysulphate of iron		
Nitrate of cobalt	54.5	240 parts
copper	54.5	240
alumina	54.5	240
lime		300
magnesia	180.5	694

Names of the substances.	Temperature.	240 parts of alcohol, dissolve.
Muriat of zinc	54.5	240 parts
alumina	54.5	240
magnesia	180.5	1313
iron	180.5	240
copper	180.5	240
Acetat of lead	113	
copper		
Nitrat of zinc decomposed		
iron decomposed		
bismuth decomposed		

2. *Substances dissolved in small quantities.*

Names of the substances.	240 parts of alcohol, at the boiling temperature, dissolve
Muriat of lime	240 parts
Nitrat of ammonia	214
Oxymuriat of mercury	212
Succinic acid	177
Acetat of soda	112
Nitrat of silver	100
Refined sugar	59
Boracic acid	48
Nitrat of soda	23
Acetat of copper	18
Muriat of ammonia	17
Arseniat of potash	9
Superoxalat of potash	7
Nitrat of potash	5
Muriat of potash	5
Arseniat of soda	4
White oxide of arsenic	3
Tartrat of potash	1
Nitrat of lead	
Carbonat of ammonia	

3. *Substances insoluble in alcohol.*

Sugar of milk	Sulphat of potash
Borax	soda
Tartar	magnesia
Alum	Sulphite of soda
Sulphat of ammonia	Tartrite of soda and potash
lime	Nitrat of mercury
barytes	Muriat of lead
iron	silver
copper	Common salt
silver	Carbonat of potash
mercury	soda
zinc	

These experiments were made chiefly by Macquer and Wenzel. The alcohol employed by Macquer was of the specific gravity 0.840. Wenzel does not give the density of his alcohol; but as he compares it with that of Macquer, we may suppose it nearly of the same strength. As the solubility of salts depends upon the strength of the alcohol employed, the experiments of these chymists must be considered as defective, because they have confined themselves to one particular density. This defect is in part supplied by the following very valuable table of Mr. Kirwan's, constructed from his own experiments.

Solubility of salts in 100 *parts of alcohol of different densities.*

Salts.	Alcohol of 0.900	0.872	0.848	0.834	0.817
Sulphat of soda	0.	0.	0.	0.	0.
Sulphat of magnesia	1.	1.	0.	0.	0.
Nitrat of potash	2.76	1.		0.	0.
Nitrat of soda	10.5	6.		0.38	0.
Muriat of potash	4 62	1.66		0.38	0.
Muriat of soda	5.8	3.67		0.5	
Muriat of ammonia	6.5	4.75		1.5	
Muriat of magnesia, dried at 120°	21.25		23.75	36.25	50.
Muriat of barytes	1.		0.29	0.185	0.09
Ditto crystallized	1.56		0.43	0.32	0.06
Acetat of lime	2.4		4.12	4.75	4.88

When alcohol, containing certain saline bodies in solution, is set on fire, its flame is often tinged of different colours according to the body. Thus nitrat of strontian tinges it purple; boracic acid and cupreous salts tinge it green; muriat of lime gives it a red colour; nitre and oxymuriat of mercury a yellow colour.

The affinities of alcohol are but imperfectly known. Those stated by Bergmann are water, ether, volatile oil, alkaline sulphurets.

Alcohol is also used for a very fine, impalpable powder, which women in the East make use of. Dr. Shaw, in his Travels, speaking of the women in Barbary, says, that none of these ladies think themselves completely dressed until they have tinged their hair and edges of their eyelids with *al-ka-hol*, the powder of lead ore. From this impalpable powder the name was transferred to other subtile powders, and afterward to spirit of wine exalted to its highest purity and perfection.

ALCOR, in astronomy, a small star adjoining to the large bright one in the middle of the tail of ursa major. The word is Arabic. It is a proverb among the Arabians, applied

to one who pretends to see small things, but overlooks much greater: Thou canst see Alcor, and yet not see the full moon.

ALCYONIUM, in zoology, a genus of zoophytes, the characters of which are, that the animal grows in the form of a plant: the stem or root is fixed, fleshy, gelatinous, spongy, or coriaceous, with a cellular epidermis, penetrated with stellated pores, and shooting out tentaculated oviparous hydræ. There are 28 species, as A. *arboreum*, with woody stem, obtuse branches, and pores in the form of pimples, found in Norway, in the white and Indian seas, sometimes of the human height. A. *digitatum*, stemless, oblong, coriaceous, and rugose, called also dead man's hand, &c. See Plate Nat. Hist. fig. 11.

ALDEBARAN, in astronomy, a star of the first magnitude, called in English the Bull's eye, being the eye of the constellation Taurus. Long. 6° 32′ 9″ of Gemini. Lat. 5° 29′ 40″ S.

ALDER, in botany. See Betula.

ALDERMAN, among our Saxon ancestors, was a degree of nobility answering to earl or count at present. It ranked inferior to atheling, but superior to thane. Alderman was also used, in the time of king Edgar, for a justice or judge. In modern British policy, it implies a magistrate subordinate to the mayor of a city or town corporate. The number of these magistrates is not limited, but is greater or less according to the magnitude of the place. In London they are twenty-six: each having one of the wards of the city committed to his care. This office is for life. When one dies or resigns, a wardmote is called within three days, who elect another, and return him to the court of aldermen, who are obliged to admit him to supply the vacancy. All the aldermen are justices of the peace by a charter of 15 Geo. II. The aldermen of London, &c. are exempted from serving inferior offices; nor can they be put upon assizes, or serve on juries, so long as they continue in office.

ALDROVANDA, in botany, a genus of the pentandria class and pentagynia order of plants; of which there is but one species. The calyx is divided into five parts; the petals are five, and the capsule has five valves, with ten seeds. It is a native of Italy and the Indies; and has no English name.

ALE, a fermented liquor obtained from an infusion of malt differing from beer chiefly in having a less proportion of hops. See Brewing.

This liquor, the natural substitute of wine in such countries as could not produce the grape, was originally made in Egypt. The natives of Spain also, the inhabitants of France, and the aborigines of Britain, all used an infusion of barley for their ordinary liquor; and it was called by the various names of *cælia* and *ceria* in the first country, *cerevisia* in the second, and *curmi* in the last, all literally importing only the strong water.

The method in which the ancient Britons, and other Celtic nations, made their ale, is thus described by Isidorus and Orosius: "The grain is steeped in water and made to germinate, by which its spirits are excited and set at liberty; it is then dried and ground; after which it is infused in a certain quantity of water, which being fermented, becomes a pleasant, warming, strengthening, and intoxicating liquor."

There are various sorts of ale known in Britain, particularly pale and brown: the former is brewed from malt slightly dried, and is esteemed more viscid than the latter, which is made from malt more highly dried or roasted. In Staffordshire they have a secret of fining ale in a very short time.

Ale is flatulent; and hence sometimes produces colics, and the cholera morbus: it is acescent; but it does not produce calcareous diseases, as has been asserted. If malt liquor, of any degree of strength, is become flat and tartish, as it is used, it should be drawn out of the cask into a jug, in which as many drams of powdered chalk is put as there are to be pints of liquor: thus a new fermentation will be raised, a sprightly taste will be restored to the liquor, and its acidity will be destroyed. Tart liquors of this kind are apt to produce a dysury, strangury, or a gonorrhœa; in which cases a small quantity of brandy may be taken.

The consumption of ale in these kingdoms is incredible. It was computed thirty years ago at the value of 4,000,000*l.* yearly, including Great Britain and Ireland. The duties on ale and beer make a principal branch of the revenue in Britain. They were first imposed by the 12th of Car. II. and have been continued by several subsequent acts of parliament to first Geo. III. which lays an additional duty of 3d. per barrel. In the whole, the brewer of ale and beer for sale shall pay 8s. for every barrel of either, above 6s. a barrel; and for every barrel of 6s. or under, the sum of 1s. 4d. Additional duties were laid on in 1803.

Ale Gill, is that in which the dried leaves of gill or ground ivy have been infused. It is esteemed abstersive and vulnerary, and consequently good in disorders of the breast and obstructions of the viscera.

ALE CONNER, an officer in the city of London, whose business it is to inspect the measures of public houses. Four of them are chosen or re-chosen annually by the common hall; and whatever might be their use formerly, their places are now regarded only as sinecures for decayed citizens. They are the same as ale tasters, which see.

ALE HOUSES must be licensed by justices of the peace, who take recognisances of the persons licensed, and of their sureties, *viz.* 10*l.* each that they will not suffer unlawful gaming nor other disorderly practices in their houses. Every person, excepting those who sell ale in fairs, neglecting to procure a license, is liable to a penalty of 20*l.* The license is granted on the 1st September, or within twenty days after, at a general meeting of the justices for the division to which he belongs, upon his producing a certificate to his character, unless, by living in a city or town corporate, this last circumstance is dispensed with, and continues in force for one year only. Alehouse keepers selling ale in short measure, are liable to a penalty not exceeding 40s. and not less than 10s. and likewise to a fine of 10s. for permitting tippling, &c. By the 29th Geo. II. c. 12. persons keeping alehouses in Scotland shall be licensed as in England, and the justices there shall meet annually to license alehouses; on each of which licenses a fee of 1s. is payable to the clerk of the peace.

ALE TASTER, an officer appointed in every court leet, and sworn to look to the assize and the goodness of bread and ale, or beer, within the precincts of that lordship. *Cowell.*

ALECTORIA, a stone said to be formed in the gall bladders of old cocks, to which the ancients ascribed many fabulous virtues. This is otherwise called *alectorius lapis* and *alectorolithos*, in English the *cock stone*. Modern naturalists hold the alectorius lapis to be not generated in, but swallowed down into, the stomach or gizzard of cocks and capons. It is known that many fowls swallow pebbles, which are supposed to be of service in trituration and digestion.

A-LEE, in the sea language, a term only used when the wind, crossing or flanking the line of a ship's course, presses upon the masts and sails so as to make her incline to one side, which is called the lee side: hence, when the helm is moved over to this side, it is said to be *a-lee* or *hard a-lee*.

ALEGER, an inferior sort of vinegar, made of ale or malt liquor instead of wine.

ALEMBICK, a vessel formerly used in distilling. They were usually made of glass or copper. The bottom, which contained the subject for distillation, was called, from its shape, the cucurbit; the upper part, which received and condensed the steam, was called the head, the beak being fitted into the neck of a receiver. Retorts, and the common worm still, are now more generally employed.

ALETRIS, in botany, a genus of the monogynia order and hexandria class of plants; and in the natural method ranking under the tenth order, coronariæ. The characters are: the corolla is monopetalous, funnel shaped, hexangular, much corrugated, semiquinquefid, and persistent; the stamina consist of six subulated filaments, the length of the corolla, and inserted into the base of the divisions of the corolla; the antheræ are oblong and erect: the pistillum has an ovate germen; the stylus subulated, and the length of the stamina; the stigma is trifid: the pericarpium is an ovated capsule, triquetrous, pointed, and trilocular: the seeds are numerous. There are eight species, among which are, 1. Aletris capensis, a native of the Cape of Good Hope. It is with us a stove plant. The flower is pink. 2. Aletris farinosa, a native of North America. This, though the most hardy plant of the genus, requires to be sheltered under a frame. The flowers appear in June or July, of a whitish green colour. 3. Aletris fragrans, a native of Africa, and, when placed in a stove, produces fine spikes of white flowers in March or April. 4. Aletris hyacinthoides, or Guinea aloe, produces likewise white flowers when kept in proper warmth by a stove, in the month of July. 5. Aletris hyacinthoides, the Ceylon aloe, is with us also a stove plant.

ALEXANDRIAN *manuscript*, a famous copy of the New Testament. This MS. is now preserved in the British Museum. It was sent as a present to king Charles I. from Cyrillus Lucaris, patriarch of Constantinople, by sir Thomas Rowe, ambassador from England to the Grand Seignior, about the year 1623. Cyrillus brought it with him from Alexandria, where probably it was written. In a schedule annexed to it, he gives this account: That it was written, as tradition informed him, by Thecla, a noble Egyptian lady, about 1300 years ago, not long after the council of Nice. But this high antiquity, and the authority of the tradition to which the patriarch refers, have been disputed; nor are the most accurate biblical writers agreed about its age. Grabe thinks that it might have been written before the end of the fourth century; others are of opinion that it was not written till near the end of the fifth century, or somewhat later. A fac simile was published by the late Dr. Woide.

ALEXANDRINE, a kind of verse borrowed from the French, first used in a poem called Alexander. They consist, among the French, of twelve and thirteen syllables, in alternate couplets; and, among us, of twelve. They are well characterized by Pope:

> Then, at the last, an only couplet fraught
> With some unmeaning thing they call a thought,
> A needless *Alexandrine* ends the song,
> That, like a wounded snake, drags its slow length along.
>
> *Essay on Criticism.*

ALEXIPHARMICS, in ancient medicine, were properly remedies for expelling or preventing the ill effects of poison; but some having imagined that the animal spirits, in acute distempers, were affected by a malignant poison, the term has been understood to mean medicines adapted to expel this poison by the cutaneous pores, in the form of sweat. In this sense alexipharmics are the same as sudorifics.

ALFECCA, in astronomy, the star otherwise called Alfeta and Lucida coronæ.

ALGÆ, Flags, one of the seven families or natural tribes, into which the whole vegetable kingdom is divided by Linnæus, in his Philosophia Botanica. They are defined to be plants, whose root, leaf, and stem, are all one. Under this description are comprehended all the sea weeds, and some other aquatic plants. In the sexual system they constitute the third order of the twenty-fourth class *cryptogamia*, and the fifty-seventh order in Linnæus's Fragments of a Natural Method.

ALGAROT, or Algarel, in chymistry, an Arabic term for an emetic powder, prepared from regulus of antimony, dissolved in acids, and separated by repeated lotions in warm water.

ALGEBRA, a general method of resolving mathematical problems by means of equations: or, it is a method of performing the calculations of all sorts of quantities by means of general signs or characters. At first, numbers and things were expressed by their names at full length; but afterward these were abridged, and the initials of the words used instead of them; and, as the art advanced further, the letters of the alphabet came to be employed as general representations of all kinds of quantities; and other marks were gradually introduced to express the operations and combinations, so as to entitle it to different appellations.

It has been called *specious* arithmetic by Vieta, on account of the species or letters of the alphabet, which he brought into general use; and by sir Isaac Newton it was denominated universal arithmetic, from the manner in which it performs all arithmetical operations by general symbols, or indeterminate quantities.

Some authors define algebra to be the art of resolving mathematical problems: but this is the idea of analysis, or the analytic art in general, rather than of algebra, which is only one particular species of it.

Indeed algebra properly consists of two parts: first, the method of calculating magnitudes or quantities, as rep-

resented by letters or other characters; and secondly, the manner of applying these calculations in the solution of problems.

In algebra, as applied to the resolution of problems, the first business is to translate the problem out of the common into the algebraic language, by expressing all the conditions and quantities, both known and unknown, by their proper characters, arranged in an equation, or several equations if necessary, and treating the unknown quantity, whether it be number or line, or any other thing, in the same way as if it were a known one: this forms the composition. Then the resolution, or analytic part, is the disentangling the unknown quantity from the several others with which it is connected, so as to retain it alone on one side of the equation, while all the known quantities are collected on the other side, and so giving the value of the unknown one. And as this disentangling of the quantity sought is performed by the converse of the operations by which it is connected with the others, taking them always backward in the contrary order, it hence becomes a species of the analytic art, and is called the modern analysis, in contradistinction to the ancient analysis, which chiefly respected geometry and its applications.

There have arisen great controversies and sharp disputes among authors concerning the history of the progress and improvements of algebra, arising partly from the partiality and prejudices which are natural to all nations, and partly from the want of a closer examination of the works of the older authors on this subject. From these causes it has happened that the improvements made by the writers of one nation have been ascribed to those of another; and the discoveries of an earlier author to some one of much later date. Add to this also, that the peculiar methods of many authors have been described so little in detail, that our information derived from such histories is but very imperfect, and amounting only to some general and vague ideas of the true state of the arts.

It is highly probable that the Indians or Arabians first invented the noble art; for it may be reasonably supposed that the ancient Greeks were ignorant of it, since Pappus, in his mathematical collections, in which he enumerates their analysis, makes mention of nothing like it; and he besides speaks of a local problem, begun by Euclid, and continued by Apollonius, which none of them could fully resolve, a circumstance that could not have occurred had they been acquainted with algebra.

Diophantus was the first Greek writer on algebra, who published thirteen books about the year 800, though only six of them were translated into Latin in the year 1575. This algebra of Diophantus only extends to the solution of arithmetical indeterminate problems. Before this translation of Diophantus came out, Lucas de Burgo, a friar, published at Venice, in the year 1494, an Italian Treatise on Algebra. This author refers to others who had preceded him, and from whom he had learned the art; but their writings have not come down to us. He also assumes, that algebra came originally from the Arabs, and never mentions Diophantus, which makes it highly probable that his work was not even then known in Europe. Burgo's Treatise goes no further than quadratic equations. He was succeeded by Stifelius, who was a good author, but did not advance the science. After him came Scipio Ferreus, Cardan, Tartagilla, and some others, who proceeded to the solution of cubic equations.

In 1590, Vieta introduced his specious arithmetic, to which we have already alluded, which consists in denoting the quantities, both known and unknown, by symbols or letters. To Vieta we are indebted for the method of extracting the roots of equations by approximation, which has been since greatly improved by Raphson, Halley, Maclaurin, Simpson, and others.

Vieta was followed by Oughtred and Harriot; the former invented several compendious characters to show the sums, differences, rectangles, squares, cubes, &c. of any given numbers; the latter left behind him his Analysis, which is highly esteemed at this day. In 1657, Des Cartes published his geometry, in which he made use of the literal calculus, and the algebraic rules of Harriot: he applied his method to the higher geometry, explaining the nature of curves by equations, and adding the constructions of cubic, biquadratic, and other higher equations.

The elements of the art were compiled and published by Kersey, in 1671, in which specious arithmetic, and the nature of equations, are largely explained and illustrated by a variety of examples. Sir Isaac Newton's Arithmetica Universalis was published in 1707, which abounds with useful and important instruction; and since his time we have had a great number of excellent treatises on the subject, from almost any of which the science may with very little difficulty be learned.

Algebra, as has been already observed, is called an universal arithmetic, and it proceeds by operations and rules similar to those in common arithmetic, founded upon the same principles. This, however, is no argument against its usefulness or evidence; since arithmetic is not to be the less valued that it is common, and is allowed to be one of the most clear and evident of the sciences. But as a number of symbols are admitted into this science, being necessary for giving it that extent and generality which is its greatest excellence; the import of those symbols is to be clearly stated, that no obscurity or error may arise from the frequent use and complication of them. Thus,

The relation of equality is expressed by the sign $=$; thus to express that the quantity represented by a is equal to that which is represented by b, we write $a=b$. But if we would express that a is greater than b, we write $a \succ b$; and if we would express algebraically that a is less than b, we write $a \prec b$.

Quantity is what is made up of parts, or is capable of being greater or less. It is increased by Addition, and diminished by Subtraction; which are therefore the two primary operations that relate to quantity. Hence it is, that any quantity may be supposed to enter into algebraic computations two different ways, which have contrary effects; either as an increment, or as a decrement; that is, as a quantity to be added, or as a quantity to be subtracted. The sign $+$, plus, is the mark of Addition, and the sign $-$, minus, of Subtraction. Thus the quantity being represented by a, or $+a$, imports that a is to be added, or represents an increment; but $-a$ imports that a is to be subtracted and represents a decrement.

When several such quantities are joined, the signs serve to show which are to be added, and which are to be subtracted. Thus $+ a + b$ denotes the quantity that arises when a and b are both considered as increments, and therefore expresses the sum of a and b. But $+ a - b$ denotes the quantity that arises when from the quantity a the quantity b is subtracted; and expresses the excess of a above b. When a is greater than b, then $a - b$ is itself an increment; when $a = b$, then $a - b = 0$; and when a is less than b, then $a - b$ is itself a decreement.

As Addition and Subtraction are opposite, or an increment is opposite to a decreement, there is an analogous opposition between the affections of quantities that are considered in the mathematical sciences. As between excess and defect; between the value of effects or money due to a man, and money due by him; a line drawn toward the right and a line drawn to the left; gravity and levity; elevation above the horizon and depression below it. When two quantities, equal in respect to magnitude, but of those opposite kinds, are joined together, and conceived to take place in the same subject, they destroy each other's effect, and their amount is nothing. Thus 100*l.* due to a man, and 100*l.* due by him, balance each other; and in estimating his stock may be both neglected.

A quantity that is to be added is likewise called a positive quantity; and a quantity to be subtracted is said to be negative: they are equally real, but opposite to each other, so as to take away each other's effect, in any operation, when they are equal as to quantity. Thus $3 - 3 = 0$, and $a - a = 0$. But though $+ a$ and $- a$ are equal as to quantity, we do not suppose in Algebra that $+ a = - a$; because to infer equality in this science, they must not only be equal as to quantity, but of the same quality, that in every operation the one may have the same effect as the other. A decreement may be equal to an increment; but it has in all operations a contrary effect. It is on account of this contrariety that a negative quantity is said to be less than nothing, because it is opposite to the positive, and diminishes it when joined to it, whereas the addition of 0 has no effect. But a negative is to be considered no less as a real quantity than the positive. Quantities that have no sign prefixed to them are understood to be positive.

The number prefixed to a letter is called the numeral co-efficient, and shows how often the quantity represented by the letter is to be taken. Thus $2a$ imports that the quantity represented by a is to be taken twice; $3a$ that it is to be taken thrice, and so on. When no number is prefixed, unit is understood to be the co-efficient. Thus 1 is the co-efficient of a or of b.

Quantities are said to be like or similar, that are represented by the same letter, or letters equally repeated. Thus, $+ 3a$ and $- 5a$ are like; but a and b, or a and aa, are unlike.

A quantity is said to consist of as many terms as there are parts joined by the signs $+$ or $-$; thus $a + b$ consists of two terms, and is called a binomial; $a + b + c$ consists of three terms, and is called a trinomial. These are called compound quantities: a simple quantity consists of one term only, as $+ a$, or $+ ab$, or $+ abc$.

OF ADDITION.

Case I. To add quantities that are like and have like signs.

Rule. Add together the co-efficients, to their sum prefix the common sign, and subjoin the common letter or letters.

EXAMPLES.

To $+ 5a$	to $- 6b$	to $a + b$
Add $+ 4a$	add $- 2b$	add $3a + 5b$
Sum $+ 9a$	Sum $- 8b$	Sum $4a + 6b$

To $3a - 4x$
add $5a - 8x$

Sum $8a - 12x$

Case II. To add quantities that are like but have unlike signs.

Rule. Subtract the lesser co-efficient from the greater, prefix the sign of the greater to the remainder, and subjoin the common letter or letters.

EXAMPLES.

To $- 4a$	$+ 5b - 6c$	
Add $+ 7a$	$- 3b + 8c$	
Sum $+ 3a$	$2b + 2c$	
To $a + 6x - 5y + 8$	$2a - 2b$	
Add $- 5a - 4x + 4y - 3$	$- 2a + 2b$	
Sum $- 4a + 2x - y + 5$	$0 \ . \ . \ 0$	

This rule is easily deduced from the nature of positive and negative quantities.

If there are more than two quantities to be added together, first add the positive together into one sum, and then the negative, by Case I. Then add these two sums together, by Case II.

$+ 8abx$
$- 7abx$
$+ 10abx$
$- 12abx$

Sum of the positive $+ 18abx$
Sum of the negative $- 19abx$

Sum of all $- abx$

Case III. To add quantities that are unlike.

Rule. Set them all down one after another, with their signs and co-efficients prefixed.

EXAMPLES.

To $+ 2a$	$+ 3a$
Add $+ 3b$	$- 4x$
Sum $2a + 3b$	$3a - 4x$

To $4a + 4b + 3c$
Add $- 4x - 4y + 3z$

Sum $4a + 4b + 3c - 4x - 4y + 3z$

OF SUBTRACTION.

GENERAL RULE. Change the signs of the quantity to be subtracted into their contrary signs, and then add it so changed to the quantity from which it was to be subtracted (by the preceding rules:) the sum arising by this addition is the remainder. For, to subtract any quantity, either positive or negative, is the same as to add the opposite kind.

EXAMPLES.

From	$+5a$	$8a - 7b$
Subtract	$+3a$	$3a + 4b$
Remainder	$5a - 3a$, or $2a$	$5a - 11b$

From	$2a - 3x + 5y - 6$
Subtract	$6a + 4x + 5y + 4$
Remainder	$-4a - 7x \quad 0 \quad -10$

It is evident, that to subtract or take away a decrement is the same as adding an equal increment. If we take away $-b$ from $a-b$, there remains a; and if we add $+b$ to $a-b$, the sum is likewise a. In general, the subtraction of a negative quantity is equivalent to adding its positive value.

OF MULTIPLICATION.

In Multiplication the general Rule for the signs is, That when the signs of the factors are like (*i.e.* both $+$, or both $-$) the sign of the product is $+$; but when the signs of the factors are unlike, the sign of the product is $-$.

Case I. When any positive quantity, $+a$, is multiplied by any positive number, $+n$, the meaning is, that $+a$ is to be taken as many times as there are units in n; and the product is evidently na.

Case II. When $-a$ is multiplied by n, then $-a$ is to be taken as often as there are units in n, and the product must be $-na$.

Case III. Multiplication by a positive number implies a repeated addition: but multiplication by a negative implies a repeated subtraction. And when $+a$ is to be multiplied by $-n$, the meaning is, that $+a$ is to be subtracted as often as there are units in n. Therefore the product is negative, being $-na$.

Case IV. When $-a$ is to be multiplied by $-n$, then $-a$ is to be subtracted as often as there are units in n; but to subtract $-a$ is equivalent to adding $+a$, consequently the product is $+na$.

The IId and IVth Cases may be illustrated in the following manner.

By the definitions, $+a-a=0$; therefore, if we multiply $+a-a$ by n, the product must vanish or be 0, because the factor $a-a$ is 0. The first term of the product is $+na$ (by Case I.) Therefore the second term of the product must be $-na$, which destroys $+na$; so that the whole product must be $+na-na=0$. Therefore $-a$ multiplied by $+n$ gives $-na$.

In like manner, if we multiply $+a-a$ by $-n$, the first term of the product being $-na$, the latter term of the product must be $+na$, because the two together must destroy each other, or their amount be 0, since one of the factors (*viz.* $a-a$) is 0. Therefore $-a$ multiplied by $-n$ must give $+na$.

In this general doctrine the multiplicator is always considered as a number. A quantity of any kind may be multiplied by a number; but a pound is not to be multiplied by a pound, or a debt by a debt, or a line by a line. We shall hereafter consider the analogy that there is betwixt rectangles in geometry and a product of two factors.

If the quantities to be multiplied are simple quantities, find the sign of the product by the last rule; after it place the product of the co-efficients, and then set down all the letters after one another, as in one word.

EXAMPLES.

Mult.	$+a$	$-2a$	$6x$
By	$+b$	$+4b$	$-5a$
Prod.	$+ab$	$-8ab$	$-30ax$

Mult.	$-8x$	$+3ab$
By	$-4a$	$-5ac$
Prod.	$+32ax$	$-15aabc$

To multiply compound quantities, you must multiply every part of the multiplicand by all the parts of the multiplier taken one after another, and then collect all the products into one sum: that sum shall be the product required.

EXAMPLES.

Mult.	$a+b$	$2a-3b$
By	$a+b$	$4a+5b$
Prod.	$aa+ab$	$8aa-12ab$
	$+ab+bb$	$+10ab-15bb$
Sum	$aa+2ab+bb$	$8aa-2ab-15bb$

Mult.	$2a-4b$	$xx-ax$
By	$2a+4b$	$x+a$
Prod.	$4aa-8ab$	$xxx-axx$
	$+8ab-16bb$	$+axx-aax$
Sum	$4aa \cdot\cdot 0. -16bb$	$xxx \cdot\cdot 0. -aax$

Mult. $aa+ab+bb$
By $a-b$

Prod. $aaa+aab+abb$
$-aab-abb-bbb$

Sum $aaa \cdots 0 \cdots\cdot 0. -bbb$

Products that arise from the multiplication of two, three, or more quantities, as abc, are said to be of two, three, or more dimensions; and those quantities are called factors or roots.

If all the factors are equal, then these products are called powers; as aa, or aaa, are powers of a. Powers are expressed sometimes by placing above the root to the right hand a figure expressing the number of factors that produce them. Thus,

a	is called the	1st	power of the root a, and is shortly expressed thus,	a
aa		2d		a^2
aaa		3d		a^3
$aaaa$		4th		a^4
$aaaaa$		5th		a^5

These figures, which express the number of factors that produce powers, are called their indices or exponents; thus 2 is the index of a^2. And powers of the same root are multiplied by adding their exponents. Thus $a^2 \times a^3 = a^5$. $a^4 \times a^3 = a^7$. $a^3 \times a = a^4$.

Sometimes it is useful, not actually to multiply compound quantities, but to set them down with the sign of multiplication ($\times$) between them, drawing a line over each of the compound factors. Thus, $\overline{a+b} \times \overline{a-b}$ expresses the product of $a+b$ multiplied by $a-b$.

OF DIVISION.

The same rule for the signs is to be observed in Division as in Multiplication; that is, if the signs of the dividend and divisor are like, the sign of the quotient must be +; if they are unlike, the sign of the quotient must be —. This will be easily deduced from the rule in Multiplication, if you consider that the quotient must be such a quantity as, multiplied by the divisor, shall give the dividend.

The general rule in Division is, to place the dividend above a small line, and the divisor under it, expunging any letters that may be found in all the quantities of the dividend and divisor, and dividing the co-efficients of all the terms by any common measure. Thus, when you divide $10ab + 15ac$ by $20ad$, expunging a out of all the terms, and dividing all the co-efficients by 5, the quotient is

$$\frac{2b + 3c}{4d}; \text{ and}$$

$$2b) ab + bb \left(\frac{a+b}{2}.\right.$$

$$12ab) 30ax - 54ay \left(\frac{5x - 9y}{2b}.\right.$$

$$4aa) 8ab + 6ac \left(\frac{4b + 3c}{2a}.\right.$$

$$\text{And } 2bc) 5abc \left(\frac{5a}{2}.\right.$$

Powers of the same root are divided by subtracting their exponents, as they are multiplied by adding them. Thus, if you divide a^5 by a^2, the quotient is a^{5-2}, or a^3. And b^6 divided by b^4, gives b^{6-4}, or b^2; and $a^7 b^5$ divided by $a^2 b^3$, gives $a^5 b^2$ for the quotient.

If the quantity to be divided is compound, then you must range its parts according to the dimensions of some one of its letters, as in the following example. In the dividend $a^2 + 2ab + b^2$, they are ranged according to the dimensions of a, the quantity a^2, where a is of two dimensions, being placed first, $2ab$, where it is of one dimension, next, and b^2, where a is not at all, being placed last. The divisor must be ranged according to the dimensions of the same letters; then you are to divide the first term of the dividend by the first term of the divisor, and to set down the quotient, which in this example is a; then multiply this quotient by the whole divisor, and subtract the product from the dividend, and the remainder shall give a new dividend, which in this example is $ab + b^2$, thus,

$$\begin{array}{l} a+b)\ a^2 + 2ab + b^2\ (a+b \\ \quad a^2 + ab \\ \hline \\ \qquad\quad ab + b^2 \\ \qquad\quad ab + b^2 \\ \hline \\ \qquad\quad 0 \quad 0 \end{array}$$

Divide the first term of this new dividend by the first term of the divisor, and set down the quotient, which in this example is b, with its proper sign. Then multiply the whole divisor by this part of the quotient, and subtract the product from the new dividend; and if there is no remainder, the division is finished. If there is a remainder, you are to proceed after the same manner till no remainder is left, or till it appears that there will be always a remainder.

Some examples will illustrate this operation.

EXAMPLE I.

$$\begin{array}{l} a+b)\ a^2 - b^2\ (a-b \\ \quad a^2 + ab \\ \hline \\ \qquad\quad -ab - b^2 \\ \qquad\quad -ab - b^2 \\ \hline \\ \qquad\quad 0 \quad 0 \end{array}$$

EXAMPLE II.

$$\begin{array}{l} a-b)\ aaa - 3aab + 3abb - bbb\ (aa - 2ab + bb \\ \quad aaa - aab \\ \hline \\ \qquad\quad -2aab + 3abb - bbb \\ \qquad\quad -2aab + 2abb \\ \hline \\ \qquad\quad\quad abb - bbb \\ \qquad\quad\quad abb - bbb \\ \hline \\ \qquad\quad 0 \quad 0 \end{array}$$

EXAMPLE III.

$$\begin{array}{l} a-b)\ aaa - bbb\ (aa + ab + bb \\ \quad aaa - aab \\ \hline \\ \qquad\quad aab - bbb \\ \qquad\quad aab - abb \\ \hline \\ \qquad\quad\quad abb - bbb \\ \qquad\quad\quad abb - bbb \\ \hline \\ \qquad\quad 0 \quad 0 \end{array}$$

EXAMPLE IV.

$$\begin{array}{l} 3a-6)\ 6aaaa - 96\ (2aaa + 4aa + 8a + 16 \\ \quad 6aaaa - 12aaa \\ \hline \\ \qquad\quad 12aaa - 96 \\ \qquad\quad 12aaa - 24aa \\ \hline \\ \qquad\quad\quad 24aa - 96 \\ \qquad\quad\quad 24aa - 48a \\ \hline \\ \qquad\quad\quad\quad 48a - 96 \\ \qquad\quad\quad\quad 48a - 96 \\ \hline \\ \qquad\quad\quad\quad 0 \quad 0 \end{array}$$

It often happens that the operation may be continued without end, and then you have an infinite series for the quotient; and by comparing the first three or four terms, you may find what law the terms observe; by which means, without any more division, you may continue the quotient as far as you please. Thus, in dividing 1 by $1 - a$, you find the quotient to be $1 + a + aa + aaa + aaaa +$ &c. which series can be continued as far as you please, by adding the powers of a.

The operation is thus:

$1 - a) 1 (1 + a + aa + aaa,$ &c.

$1 - a$

$+ a$

$+ a - aa$

$+ aa$

$+ aa - aaa$

$+ aaa$

$+ aaa - aaaa$

$+ aaaa,$ &c.

Another Example.

$$a + x) aa + xx (a - x + \frac{2xx}{a} - \frac{2x^3}{a^2} + \frac{2x^4}{a^3} -$$ &c.

$aa + ax$

$-ax + xx$

$-ax - xx$

$+ 2xx$

$+ 2xx + \frac{2x^3}{a}$

$\frac{2x^3}{a}$

$\frac{2x^3}{a} - \frac{2x^4}{a^2}$

$+ \frac{2x^4}{a^2},$ &c.

In this last example the signs are alternately + and —, the co-efficient is constantly 2 after the first two terms, and the letters are the powers of x and a; so that the quotient may be continued as far as you please without any more division.

But in division, after you come to a remainder of one term, as $2xx$ in the last example, it is commonly set down with the divisor under it, after the other terms, and these together give the quotient. Thus, the quotient in the last example is found to be $a - x + \frac{2x^2}{a + x}$. And $bb + ab$, divided by $b - a$, gives for the quotient $b + \frac{2ab}{b - a}$.

Note. The sign ÷ placed between any two quantities, expresses the quotient of the former divided by the latter. Thus $a + b \div a - x$ is the quotient of $a + b$ divided by $a - x$.

OF FRACTIONS.

In the preceding page it was said, that the quotient of any quantity a divided by b, is expressed by placing a above a small line, and b under it, thus $\frac{a}{b}$. These quotients are also called fractions; and the dividend or quantity placed above the line is called the numerator of the fraction, and the divisor or quantity placed under the line is called the denominator. Thus, $\frac{2}{3}$ expresses the quotient of 2 divided by 3; and 2 is the numerator and 3 the denominator of the fraction.

If the numerator of a fraction is equal to the denominator, then the fraction is equal to unity. Thus, $\frac{a}{b}$, and $\frac{b}{a}$, are equal to unit. If the numerator is greater than the denominator, then the fraction is greater than unit. In both these cases, the fraction is called improper. But if the numerator is less than the denominator, then the fraction is less than unit, and is called proper. Thus $\frac{5}{3}$ is an improper fraction; but $\frac{3}{4}$ and $\frac{2}{3}$ are proper fractions.

A mixt quantity is that whereof one part is an integer, and the other a fraction; as $3\frac{4}{5}$, and $5\frac{2}{3}$, and $a + \frac{a^2}{b}$.

PROB. I. *To reduce a Mixt Quantity to an Improper Fraction.*

RULE. Multiply the part that is an integer by the denominator of the fractional part; and to the product add the numerator; under their sum place the former denominator.

Thus $2\frac{3}{5}$, reduced to an improper fraction, gives $\frac{13}{5}$; $a + \frac{a^2}{b} = \frac{ab + a^2}{b}$; and $a - x + \frac{a^2 - ax}{x} = \frac{a^2 - x^2}{x}$.

PROB. II. *To reduce an Improper Fraction to a Mixt Quantity.*

RULE. Divide the numerator of the fraction by the denominator, and the quotient shall give the integral part; the remainder set over the denominator shall be the fractional part.

Thus, $\frac{12}{5} = 2\frac{2}{5}$; $\frac{ab + a^2}{b} = a + \frac{a^2}{b}$; $\frac{ax + 2xx}{a + x} = x + \frac{x^2}{a + x}$; $\frac{aa + xx}{a - x} = a + x + \frac{2xx}{a - x}$.

PROB. III. *To reduce Fractions of different Denominators, to Fractions of equal Value that shall have the same Denominator.*

RULE. Multiply each numerator, separately taken into all the denominators but its own, and the products shall give the new numerators. Then multiply all the denominators into one another, and the product shall give the common denominator. Thus,

The fractions $\frac{a}{b}, \frac{b}{c}, \frac{c}{d}$, are respectively equal to $\frac{acd}{bcd}, \frac{bbd}{bcd}, \frac{ccb}{bcd}$, these fractions, which have the same denominator bcd. And the fractions $\frac{2}{3}, \frac{3}{4}, \frac{4}{5}$; are respectively equal to these $\frac{40}{60}, \frac{45}{60}, \frac{48}{60}$.

PROB. IV. *To Add and Subtract Fractions.*

RULE. Reduce them to a common denominator, and add or subtract the numerators; the sum or difference set over the common denominator, is the sum or remainder required.

Thus, $\frac{a}{b} + \frac{c}{d} + \frac{d}{e} = \frac{ade + bce + d^2b}{bde}$; $\frac{a}{b} - \frac{c}{d} = \frac{ad - bc}{bd}$; $\frac{2}{3} + \frac{3}{4} = \frac{8+9}{12} = \frac{17}{12} = 1\frac{5}{12}$; $\frac{3}{4} - \frac{2}{3} = \frac{9-8}{12} = \frac{1}{12}$;

$$\frac{4}{5} - \frac{3}{4} = \frac{16-15}{20} = \frac{1}{20};$$

$$\frac{x}{2} - \frac{x}{3} = \frac{3x-2x}{6} = \frac{x}{6}.$$

PROB. V. *To Multiply Fractions.*

RULE. Multiply their numerators one into another to obtain the numerator of the product; and their denominators multiplied into one another, shall give the denominator of the product.

Thus, $\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$; $\frac{2}{3} \times \frac{4}{5} = \frac{8}{15}$;

and $\frac{a+b}{c} \times \frac{a-b}{d} = \frac{a^2-b^2}{cd}$.

If a mixt quantity is to be multiplied, first reduce it to the form of a fraction, by Prob. I. And if an integer is to be multiplied by a fraction, you may reduce it to the form of a fraction by placing unit under it.

EXAMPLES.

$5\frac{2}{3} \times \frac{3}{4} = \frac{17}{3} \times \frac{3}{4} = \frac{51}{12}$; $9 \times \frac{2}{3} = \frac{9}{1} \times \frac{2}{3} = \frac{18}{3} = 6$; $b + \frac{bx}{a} \times \frac{a}{x} = \frac{ba+bx}{a} \times \frac{a}{x} = \frac{a^2b + abx}{ax}$

$$= \frac{ab+bx}{x} = b + \frac{ab}{x}.$$

PROB. VI. *To Divide Fractions.*

RULE. Multiply the numerator of the dividend by the denominator of the divisor, their product shall give the numerator of the quotient. Then multiply the denominator of the dividend by the numerator of the divisor, and their product shall give the denominator. Thus

$$\frac{4}{5} \Big) \frac{2}{3} - \Big(\frac{10}{12}; \frac{3}{7} \Big) \frac{5}{8} - \Big(\frac{35}{24}; \frac{c}{d} \Big) \frac{a}{b} - \Big(\frac{ad}{cb}; \frac{a+b}{a-b} \Big) \frac{a-b}{a}$$

$$\Big(\frac{a^2 - 2ab + b^2}{a^2 + ab}.$$

These last four Rules are easily demonstrated from the definition of a fraction.

1. It is obvious that the fractions $\frac{a}{b}, \frac{c}{d}, \frac{e}{f}$, are respectively equal to $\frac{adf}{bdf}, \frac{cbf}{dbf}, \frac{ebd}{fbd}$; since, if you divide adf by bdf, the quotient will be the same as of a divided by b; and cbf divided by dbf, gives the same quotient as c divided by d; and ebd divided by fbd, the same quotient as e divided by f.

2. Fractions reduced to the same denominator are added by adding their numerators and subscribing the common denominator. I say $\frac{a}{b} + \frac{c}{b} = \frac{a+c}{b}$. For, call $\frac{a}{b} = m$, and $\frac{c}{b} = n$, and it will be $a = mb$, $c = nb$, and $mb + nb = a + c$, and $m + n = \frac{a+c}{b}$; that is, $\frac{a}{b} + \frac{c}{b} = \frac{a+c}{b}$. After the same manner, $\frac{a}{b} - \frac{c}{b} = m - n = \frac{a-c}{b}$.

3. I say, $\frac{a}{b} \times \frac{c}{d} (= m \times n) = \frac{ac}{bd}$; for $bm = a$, $dn = c$; and $bdmn = ac$, and $mn = \frac{ac}{bd}$; that is, $\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$.

4. I say, $\frac{a}{b}$ divided by $\frac{c}{d}$, or $\frac{m}{n}$, gives $\frac{ad}{cb}$; for $mb = a$, and $mbd = ad$; $nd = c$, and $nbd = cb$; therefore $\frac{mbd}{nbd} = \frac{ad}{cb}$; that is, $\frac{m}{n} = \frac{ad}{cb}$.

PROB. VII. *To find the greatest common Measure of two Numbers; that is, the greatest Number that can divide them both without a Remainder.*

RULE. First divide the greater number by the lesser, and if there is no remainder, the lesser number is the greatest common divisor required. If there is a remainder, divide your last divisor by it; and thus proceed continually dividing the last divisor by its remainder, till

there is no remainder left, and then the last divisor is the greatest common measure required. Thus, the greatest common measure of 45 and 63 is 9; and the greatest common measure of 256 and 48 is 16.

45) 63 (1
45
18) 45 (2
36
9) 18 (2
18
0

48) 256 (5
240
16) 48 (3
48
0

Much after the same manner the greatest common measure of Algebraic quantities is discovered; only the remainders that arise in the operation are to be divided by their simple divisors, and the quantities are always to be ranged according to the dimensions of the same letter.

Thus, to find the greatest common measure of $a^2 - b^2$ and $a^2 - 2ab + b^2$;

$a^2 - b^2) a^2 - 2ab + b^2 (1$
$a^2 - b^2$

$-2ab + 2b^2$ remainder,

which divided by $-2b$ is reduced to

$a - b) a^2 - b^2 (a + b$
$a^2 - b^2$

0 0

Therefore $a - b$ is the greatest common measure required.

The ground of this operation is, that any quantity that measures the divisor and the remainder, if there is any, must also measure the dividend; because the dividend is equal to the sum of the divisor multiplied into the quotient, and of the remainder added together. Thus, in the last example, $a - b$ measures the divisor $a^2 - b^2$, and the remainder $-2ab + 2b$; it must therefore likewise measure their sum $a^2 - 2ab + b^2$. You must observe in this operation, to make that the dividend which has the highest powers of the letter according to which the quantities are ranged.

PROB. VIII. *To reduce any Fraction to its lowest Terms.*

RULE. Find the greatest common measure of the numerator and denominator; divide them by that common measure, and place the quotients in their room, and you shall have a fraction equivalent to the given fraction expressed in the least terms. Thus,

$\frac{25bc}{25bc} \Big) \frac{75abc}{125bcx} = \frac{3a}{5x}$; $\frac{156aa + 156ab}{572aa - 572ab} = \frac{3a + 3b}{11a - 11b}$; $\frac{a^2 - b^2}{a^2 - 2ab + b^2} = \frac{a + b}{a - b}$;

$\frac{a^3 - b^2a}{a^2 + 2ab + b^2} = \frac{a^2 - ba}{a + b}$; $\frac{a^4 - b^4}{a^5 - a^3b^2} = \frac{a^2 + b^2}{a^3}$.

When unit is the greatest common measure of the numbers and quantities, then the fraction is already in its lowest terms. Thus, $\frac{3ab}{5dc}$ cannot be reduced lower.

And numbers, whose greatest common measure is unit, are said to be prime to one another.

If it is required to reduce a given fraction to a fraction equal to it that shall have a given denominator, you must multiply the numerator by the given denominator, and divide the product by the former denominator, the quotient, set over the given denominator, is the fraction required. Thus $\frac{a}{b}$ being given, and it being required to reduce it to an equal fraction whose denominator shall be c; find the quotient of ac divided by b, and it shall be the numerator of the fraction required.

OF THE INVOLUTION OF QUANTITIES.

The products arising from the continual multiplication of the same quantity, were before called the powers of that quantity. Thus a, a^2, a^3, a^4, &c. are the powers of a; and ab, a^2b^2, a^3b^3, a^4b^4, &c. are the powers of ab. And the rule given for the multiplication of powers of the same quantity was, to "Add the exponents, and make their sum the exponent of the product." Thus $a^4 \times a^5 = a^9$; and $a^2b^3 \times a^6b^2 = a^9b^6$. In the above place you have the rule for dividing powers of the same quantity, which is, "To subtract the exponents, and make the difference the exponent of the quotient."

Thus, $\frac{a^6}{a^4} = a^{6-4} = a^2$; and $\frac{a^5b^3}{a^4b} = a^{5-4}b^{3-1} = ab^2$.

If you divide a lesser power by a greater, the exponent of the quotient must, by this rule, be negative. Thus, $\frac{a^4}{a^6} = a^{4-6} = a^{-2}$. But $\frac{a^4}{a^6} = \frac{1}{a^2}$; and hence $\frac{1}{a^2}$ is expressed also by a^2 with a negative exponent, or a^{-2}.

It is also obvious, that $\frac{a}{a} = a^{1-1} = a^0$; but $\frac{a}{a} = 1$, and therefore $a^0 = 1$. After the same manner, $\frac{1}{a} = \frac{a^0}{a} = a^{0-1} = a^{-1}$; $\frac{1}{aa} = \frac{a^0}{a^2} = a^{0-2} = a^{-2}$; $\frac{1}{aaa} = a^{0-3} = a^{-3}$; so that the quantities a, 1, $\frac{1}{a}, \frac{1}{a^2}, \frac{1}{a^3}, \frac{1}{a^4}$, &c. may be expressed thus, a^1, a^0, a^{-1}, a^{-2}, a^{-3}, a^{-4}, &c. Those are called the negative powers of a, which have negative exponents; but they are at the same time positive powers of $\frac{1}{a}$, or a^{-1}.

Negative powers, as well as positive, are multiplied by adding, and divided by subtracting, their exponents. Thus the product of a^{-2} ($\text{or } \frac{1}{a^2}$) multiplied by a^{-3} ($\text{or } \frac{1}{a^3}$) is $a^{-2-3} = a^{-5}$

(or $\frac{1}{a^5}$); also $a^{-6} \times a^4 = a^{-6+4} = a^{-2}$ (or $\frac{1}{a^2}$); and $a^{-3} \times a^3 = a^0 = 1$. And, in general, any positive power of a multiplied by a negative power of a of an equal exponent, gives unit for the product; for the positive and negative exponents destroy each other, and the product gives a^0, which is equal to unit.

Likewise $\frac{a^{-5}}{a^{-2}} = a^{-5+2} = a^{-3} = \frac{1}{a^3}$; and $\frac{a^{-2}}{a^{-5}} = a^{-2+5} = a^3$. But also, $\frac{a^{-2}}{a^{-5}} = \frac{1}{a^2} \times \frac{1}{a^{-5}} = \frac{1}{a^{-3}}$; therefore $\frac{1}{a^{-3}} = a^3$. And, in general, "any quantity placed in the denominator of a fraction, may be transposed to the numerator, if the sign of its exponent be changed." Thus $\frac{1}{a^3} = a^{-3}$, and $\frac{1}{a^{-3}} = a^3$.

The quantity a^m expresses any power of a in general; the exponent (m) being undetermined; and a^{-m} expresses $\frac{1}{a^m}$, or a negative power of a of an equal exponent: and $a^m \times a^{-m} = a^{m-m} = a^0 = 1$ is their product. a^n expresses any other power of a; $a^m \times a^n = a^{m+n}$ is the product of the powers a^m and a^n, and a^{m-n} is their quotient.

To raise any simple quantity to its second, third, or fourth power, is to add its exponent twice, thrice, or four times to itself; therefore the second power of any quantity is had by doubling its exponent, and the third by trebling its exponent; and, in general, the power expressed by m of any quantity is had by multiplying the exponent by m, as is obvious from the multiplication of powers. Thus the second power or square of a is $a^{2 \times 1} = a^2$; its third power or cube is $a^{3 \times 1} = a^3$; and the mth power of a is $a^{m \times 1} = a^m$. Also, the square of a^4 is $a^{2 \times 4} = a^8$; the cube of a^4 is $a^{3 \times 4} = a^{12}$; and the mth power of a^4 is $a^{4 \times m}$. The square of abc is $a^2b^2c^2$, the cube is $a^3b^3c^3$, the mth power $a^mb^mc^m$.

The raising of quantities to any power is called Involution; and any simple quantity is involved by multiplying the exponent by that of the power required, as in the preceding examples.

The co-efficient must also be raised to the same power by a continual multiplication of itself by itself, as often as unit is contained in the exponent of the power required. Thus the cube of $3ab$ is $3 \times 3 \times 3 \times a^3b^3 = 27\,a^3b^3$.

As to the signs, When the quantity to be involved is positive, it is obvious that all its powers must be positive. And when the quantity to be involved is negative, yet all its powers whose exponents are even numbers must be positive; for any number of multiplications of a negative, if the number is even, gives a positive; since $- \times - = +$, therefore $- \times - \times - \times - = + \times + = +$; and $- \times - \times - \times - \times - \times - = + \times + \times + = +$.

The power then only can be negative when its exponent is an odd number, though the quantity to be involved be negative. The powers of $-a$ are $-a$, $+a^2$, $-a^3$, $+a^4$, $-a^5$, &c. Those whose exponents are 2, 4, 6, &c. are positive; but those whose exponents are 1, 3, 5, &c. are negative.

The involution of compound quantities is a more difficult operation. The powers of any binomial $a + b$ are found by a continual multiplication of it by itself, as follows.

$$
\begin{array}{l}
a + b = \text{Root.} \\
\times\ a + b \\
\hline
a^2 + ab \\
\quad + ab + b^2 \\
\hline
a^2 + 2ab + b^2 = \text{the Square, or 2d Power.} \\
\times\ a + b \\
\hline
a^3 + 2a^2b + ab^2 \\
\quad + a^2b + 2ab^2 + b^3 \\
\hline
a^3 + 3a^2b + 3ab^2 + b^3 = \text{Cube, or 3d Power.} \\
\times\ a + b \\
\hline
a^4 + 3a^3b + 3a^2b^2 + ab^3 \\
\quad + a^3b + 3a^2b^2 + 3ab^3 + b_4 \\
\hline
a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4 = \text{Biquadrate, or 4th Power.}
\end{array}
$$

$\times\ a\ +b$

$a^5 + 4a^4b + 6a^3b^2 + 4a^2b^3 + ab^4$
$\quad + a^4b + 4a^3b^2 + 6a^2b^3 + 4ab^4 + b^5$

$a^5 + 5a^4b + 10a^3b^2 + 10a^2b^3 + 5ab^4 + b^5$ = 5th Power.

$\times\ a\ +b$

$a^6 + 5a^5b + 10a^4b^2 + 10a^3b^3 + 5a^2b^4 + ab^5$
$\quad + a^5b + 5a^4b^2 + 10a^3b^3 + 10a^2b^4 + 5ab^5 + b^6$

$a^6 + 6a^5b + 15a^4b^2 + 20a^3b^3 + 15a^2b^4 + 6ab^5 + b^6$ = 6th Power, &c.

If the powers of $a - b$ are required, they will be found the same as the preceding, only the terms in which the exponent of b is an odd number will be found negative; "because an odd number of multiplications of a negative produces a negative." Thus, the cube of $a - b$ will be found to be $a^3 - 3a^2b + 3ab^2 - b^3$; where the 2d and 4th terms are negative, the exponent of b being an odd number in these terms. In general, "the terms of any power of $a - b$ are positive and negative by turns."

It is to be observed, that "in the first term of any power of $a + b$, the quantity a has the exponent of the power required; that in the following terms, the exponents of a decrease gradually by the same difference, (*viz.* unit) and that in the last terms it is never found. The powers of b are in the contrary order; it is not found in the first term, but its exponent in the second term is unit, in the 3d term its exponent is 2; and thus its exponent increases, till in the last term it becomes equal to the exponent of the power required."

As the exponents of a thus decrease, and at the same time those of b increase, "the sum of their exponents is always the same, and is equal to the exponent of the power required." Thus in the 6th power of $a + b$, *viz.* $a^6 + 6a^5b + 15a^4b^2 + 20a^3b^3 + 15a^2b^4 + 6ab^5 + b^6$, the exponents of a decrease in this order, 6, 5, 4, 3, 2, 1, 0; and those of b increase in the contrary order, 0, 1, 2, 3, 4, 5, 6. And the sum of their exponents in any term is always 6.

To find the co-efficient of any term, the co-efficient of the preceding term being known; you are to "divide the co-efficient of the preceding term by the exponent of b in the given term, and to multiply the quotient by the exponent of a in the same term, increased by unit." Thus to find the co-efficients of the terms of the 6th power of $a + b$, you find the terms are a^6, a^5b, a^4b^2, a^3b^3, a^2b^4, ab^5, b^6; and you know the co-efficient of the first term is unit, therefore, according to the Rule, the co-efficient of the second term will be

$$\frac{1}{1} \times \overline{5+1} = 6;$$

that of the third term will be

$$\frac{6}{2} \times \overline{4+1} = 3 \times 5 = 15;$$

that of the fourth term will be

$$\frac{15}{3} \times \overline{3+1} = 5 \times 4 = 20;$$ and those of the following terms will be 15, 6, 6, agreeable to the preceding table.

In general, if $a + b$ is to be raised to any power m, the terms, without their co-efficients, will be, a^m, $a^{m-1}b$, $a^{m-2}b^2$, $a^{m-3}b^3$, $a^{m-4}b^4$, $a^{m-5}b^5$, &c. continued till the exponent of b becomes equal to m.

The co-efficients of the respective terms, according to the last Rule, will be

$$1, m, m \times \frac{m-1}{2}, m \times \frac{m-1}{2} \times \frac{m-2}{3},$$

$$m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4},$$

$$m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \times \frac{m-4}{5},$$

&c. continued until you have one co-efficient more than there are units in m.

It follows therefore by these last Rules, that $\overline{a+b}^m$

$$= a^m + ma^{m-1}b + m \times \frac{m-1}{2} \times a^{m-2}b^2 + m \times \frac{m-1}{2} \times \frac{m-2}{3} \times a^{m-3}b^3 + m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \times a^{m-4}b^4 +,$$ &c. which is the general theorem for raising a quantity consisting of two terms to any power m.

If a quantity consisting of three or more terms is to be involved, "you may distinguish it into two parts, considering it as a binomial, and raise it to any power by the preceding Rules; and then by the same rules you may substitute instead of the powers of these compound parts their values." Thus,

$\overline{\overline{a+b+c}}^2 = \overline{\overline{a+b}+c}^2 = \overline{a+b}^2 + 2c \times \overline{a+b} + c^2 = a^2 + 2ab + b^2 + 2ac + 2bc + c^2$. And $\overline{\overline{a+b}+c}^3 = \overline{a+b}^3 + 3c \times \overline{a+b}^2 + 3c^2 \times \overline{a+b} + c^3 = a^3 + 3a^2b + 3ab^2 + b^3 + 3a^2c + 6abc + 3b^2c + 3ac^2 + 3bc^2 + c^3$.

In these examples, $a + b + c$, is considered as composed of the compound part $a + b$ and the simple part c; and then the powers of $a + b$ are formed by the preceding rules, and substituted for $\overline{a+b}$ and $\overline{a+b}^2$.

OF EVOLUTION.

The reverse of Involution, or the resolving of powers into their roots, is called Evolution. The roots of single

quantities are easily extracted by dividing their exponents by the number that denominates the root required. Thus, the square root of a^8 is $a^{\frac{8}{2}} = a^4$; and the square root of $a^4 b^8 c^2$ is $a^2 b^4 c$. The cube root of $a^6 b^3$ is $a^{\frac{6}{3}} b^{\frac{3}{3}} = a^2 b$; and the cube root of $x^9 y^6 z^{12}$ is $x^3 y^2 z^4$. The ground of this rule is obvious from the rule for Involution. The powers of any root are found by multiplying its exponent by the index that denominates the power; and therefore, when any power is given, the root must be found by dividing the exponent of the given power by the number that denominates the kind of root that is required.

It appears from what was said of Involution, that "any power that has a positive sign, may have either a positive or negative root, if the root is denominated by any even number." Thus the square root of $+ a^2$ may be $+ a$, or $- a$, because $+ a \times + a$, or $- a \times - a$ gives $+ a^2$ for the product.

But if a power have a negative sign, "no root of it denominated by an even number can be assigned," since there is no quantity that multiplied into itself an even number of times can give a negative product. Thus the square root of $- a^2$ cannot be assigned, and is what we call an "impossible or imaginary quantity."

But if the root to be extracted is denominated by an odd number, then shall the sign of the root be the same as the sign of the given number whose root is required. Thus the cube root of $- a^3$ is $- a$, and the cube root of $- a^6 b^3$ is $- a^2 b$.

If the number that denominates the root required is a divisor of the exponent of the given power, then shall the root be only a "lower power of the same quantity." As the cube root of a^{12} is a^4, the number 3 that denominates the cube root being a divisor of 12.

But if the number that denominates what sort of root is required is not a divisor of the exponent of the given power, "then the root required shall have a fraction for its exponent." Thus the square root of a^3 is $a^{\frac{3}{2}}$; the cube root of a^5 is $a^{\frac{5}{3}}$, and the square root of a itself is $a^{\frac{1}{2}}$.

These powers that have fractional exponents are called "imperfect powers or surds;" and are otherwise expressed by placing the given power within the radical sign $\sqrt{\ }$, and placing above the radical sign the number that denominates what kind of root is required. Thus

$a^{\frac{3}{2}} = \sqrt[2]{a^3}$, $a^{\frac{5}{3}} = \sqrt[3]{a^5}$; and $\frac{m}{a^n} = \sqrt[n]{a^m}$. In numbers the square root of 2 is expressed by $\sqrt[2]{2}$, and the cube root of 4 by $\sqrt[3]{4}$.

These imperfect powers or surds are "multiplied and divided, as other powers, by adding and subtracting their exponents." Thus,

$$a^{\frac{1}{2}} \times a^{\frac{5}{2}} = a^{\frac{6}{2}} = a^3;$$

$$a^{\frac{3}{3}} \times a^{\frac{3}{4}} = a^{\frac{3}{3} + \frac{3}{4}} = a^{\frac{17}{12}} = \sqrt[12]{a^{17}};$$

$$\text{and } \frac{a^{\frac{7}{2}}}{a^{\frac{3}{2}}} = a^{\frac{7-3}{2}} = a^{\frac{4}{2}} = a^2.$$

They are involved likewise, and evolved after the same manner as perfect powers. Thus the square of $a^{\frac{2}{3}}$ is $a^{\frac{5}{3} \times \frac{3}{2}} = a^5$; the cube of $a^{\frac{2}{3}}$ is $a^{\frac{3}{3} \times \frac{2}{5}} = a^{\frac{6}{5}}$. The square root of $a^{\frac{2}{3}}$ is $a^{\frac{2}{3 \times 2}} = a^{\frac{1}{3}}$, the cube root of $a^{\frac{3}{4}}$ is $a^{\frac{1}{4}}$.

The square root of any compound quantity, as $a^2 + 2ab + b^2$ is discovered after this manner. "First, take care to dispose the terms according to the dimensions of the alphabet, as in Division; then find the square root of the first term aa, which gives a for the first member of the root. Then subtract its square from the proposed quantity, and divide the first term of the remainder ($2ab + b^2$) by the double of that member, *viz.* $2a$, and the quotient b is the second member of the root. Add this second member to the double of the first, and multiply their sum ($2a + b$) by the second member b, and subtract the product ($2ab + b^2$) from the foresaid remainder ($2ab + b^2$) and if nothing remains, then the square root is obtained; and in this example it is found to be $a + b$.

The manner of the operation is thus:

$$\begin{array}{l} a^2 + 2ab + b^2 \ (a + b \\ a^2 \\ \hline 2a + b \,)\, 2ab + b^2 \\ \quad \times b \,)\, 2ab + b^2 \\ \hline \quad 0 \ . \ 0 \end{array}$$

But if there had been a remainder, you must have divided it by the double of the sum of the two parts already found, and the quotient would have given the third member of the root.

Thus, if the quantity proposed had been $a^2 + 2ab + 2ac + b^2 + 2bc + c^2$, after proceeding as above, you would have found the remainder $2ac + 2bc + c^2$, which divided by $2a + 2b$ gives c to be annexed to $a + b$ as the third member of the root. Then adding c to $2a + 2b$, and multiplying their sum $2a + 2b + c$ by c, subtract the product $2ac + 2bc + c^2$ from the foresaid remainder: and since nothing now remains, you conclude that $a + b + c$ is the square root required.

The operation is thus:

$$\begin{array}{l} a^2 + 2ab + 2ac + b^2 + 2bc + c^2 \ (a + b + c \\ a^2 \\ \hline 2a + b \,)\, 2ab + 2ac + b^2 + 2bc + c^2 \\ \quad \times b \,)\, 2ab \qquad + b^2 \\ \hline 2a + 2b + c \,)\, 2ac + 2bc + c^2 \\ \quad \times c \,)\, 2ac + 2bc + c^2 \\ \hline \quad 0 \ . \ 0 \ . \ 0 \end{array}$$

Another Example.

$$\begin{array}{l} xx - ax + \frac{1}{4}aa \ (x - \frac{1}{2}a \\ xx \\ \hline 2x - \frac{1}{2}a \,)\, - ax + \frac{1}{4}aa \\ \quad \times - \frac{1}{2}a \,)\, - ax + \frac{1}{4}aa \\ \hline \quad 0 \ . \ 0 \end{array}$$

In general, to extract any root out of any given quantity, "First range that quantity according to the dimensions of its letters, and extract the said root out of the first term, and that shall be the first member of the root required. Then raise this root to a dimension lower by unit than the number that denominates the root required, and multiply the power that arises by that number itself; divide the second term of the given quantity by the prod-

uct, and the quotient shall give the second member of the root required."

Thus, to extract the root of the 5th power out of $a^5 + 5a^4b + 10a^3b^2 + 10a^2b^3 + 5ab^4 + b^5$, I find that the root of the 5th power out of a^5 gives a, which I raise to the 4th power, and multiplying by 5, the product is $5a^4$; then dividing the second term of the given quantity $5a^4b$ by $5a^4$, I find b to be the second member; and raising $a + b$ to the 5th power, and subtracting it, there being no remainder, I conclude that $a + b$ is the root required. If the root has three members, the third is found after the same manner from the first two considered as one member, as the second member was found from the first; which may be easily understood from what was said of extracting the square root.

In extracting roots it will often happen that the exact root cannot be found in finite terms; thus the square root of $a + x^2$ is found to be $a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} - \frac{5x^8}{128a^7}$ +, &c.

The operation is thus:

$$a^2 + x^2 \left(a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} -, \text{ &c.}\right.$$

$$\begin{array}{l} a^2 \\ \hline 2a + \frac{x^2}{2a}\Big) + x^2 \\ \times \frac{x^2}{2a}\Big) = x^2 + \frac{x^4}{4a^2} \\ \hline 2a + \frac{x^2}{a} - \frac{x^4}{8a^3}\Big) - \frac{x^4}{4a^2} \\ \times -\frac{x^4}{8a^3}\Big) = -\frac{x^4}{4a^2} - \frac{x^6}{8a^4} + \frac{x^8}{64a^6} \\ \hline + \frac{x^6}{8a^4} - \frac{x^8}{64a^6}, \text{ &c.} \end{array}$$

After the same manner, the cube root of $a^3 + x^3$ will be found to be $a + \frac{x^3}{3a^2} - \frac{x^6}{9a^5} + \frac{5x^9}{81a^8} - \frac{10x^{12}}{243a^{11}}$ +, &c.

"The general theorem which we gave for the involution of binomials, will serve also for their evolution;" because, to extract any root of a given quantity, is the same thing as to raise that quantity to a power whose exponent is a fraction that has its denominator equal to the number that expresses what kind of root is to be extracted. Thus, to extract the square root of $a + b$ is to raise $a + b$ to a power whose exponent is $\frac{1}{2}$. Now, since $\overline{a+b}^m = a^m + m \times a^{m-1} b + m \times \frac{m-1}{2} a^{m-2} b^2 + m \times \frac{m-1}{2} \times \frac{m-2}{3} \times a^{m-3} b^3$, &c.

Supposing $m = \frac{1}{2}$, you will find $\overline{a+b}^{\frac{1}{2}} = a^{\frac{1}{2}} + \frac{1}{2} \times a^{-\frac{1}{2}} b + \frac{1}{2} \times -\frac{1}{4} \times a^{-\frac{3}{2}} b^2 + \frac{1}{2} \times -\frac{1}{4} \times -\frac{1}{2} a^{-\frac{5}{2}} b^3$, &c. $= a^{\frac{1}{2}} + \frac{b}{2a^{\frac{1}{2}}} - \frac{b^2}{8a^{\frac{3}{2}}} + \frac{b^3}{16a^{\frac{5}{2}}} -$, &c.

And after this manner you will find that $\overline{a^2+x^2}^{\frac{1}{2}} = a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} -$, &c. as before.

OF PROPORTION.

When quantities of the same kind are compared, it may be considered either how much the one is greater than the other, and what is their difference; or, it may be considered how many times the one is contained in the other, or, more generally, what is their quotient. The first relation of quantities is expressed by their arithmetical ratio; the second by their geometrical ratio. That term whose ratio is inquired into is called the Antecedent, and that with which it is compared is called the Consequent.

When of four quantities, the difference betwixt the first and second is equal to the difference betwixt the third and fourth, those quantities are called Arithmetical Proportionals; as the numbers 3, 7, 12, 16; and the quantities a, $a + b$, c, $c + b$. But quantities form a series in Arithmetical Proportion, when they "increase or decrease by the same constant difference;" as these, a, $a + b$, $a + 2b$, $a + 3b$, $a + 4b$, &c. x, $x - b$, $x - 2b$, &c. or the numbers 1, 2, 3, 4, 5, &c. and 10, 7, 4, 1, -2, -5, -8, &c.

In four quantities arithmetically proportional, "the sum of the extremes is equal to the sum of the mean terms." Thus, a, $a + b$, e, $e + b$, are arithmetical proportionals, and the sum of the extremes, $(a + e + b)$ is equal to the sum of the mean terms $(a + b + e.)$ Hence, to find the fourth quantity arithmetically proportional to any three given quantities; "add the second and third, and from their sum subtract the first term, the remainder shall give the fourth arithmetical proportional required."

In a series of arithmetical proportionals, "the sum of the first and last terms is equal to the sum of any two terms equally distant from the extremes." If the first terms are a, $a + b$, $a + 2b$, &c. and the last term x, the last term but one will be $x - b$, the last but two $x - 2b$, the last but three $x - 3b$, &c. So that the first half of the terms, having those that are equally distant from the last term set under them, will stand thus:

$$\begin{array}{l} a,\ a + b,\ a + 2b,\ a + 3b,\ a + 4b, \text{ &c.} \\ x - b,\ x - 2b,\ x - 3b,\ x - 4b, \\ \hline a + x,\ a + x,\ a + x,\ a + x,\ a + x, \text{ &c.} \end{array}$$

And it is plain that if each term be added to the term above it, the sum will be $a + x$, equal to the sum of the first term a, and the last term x. From which it is plain, that "the sum of all the terms of an arithmetical progression is equal to the sum of the first and last taken half as often as there are terms," that is, the sum of an arithmetical progression is equal to the sum of the first and last terms multiplied by half the number of terms. Thus, in the preceding series, if n be the number of terms, the sum of all the terms will be $\overline{a + x} \times \frac{n}{2}$.

The common difference of the terms being b, and b not being found in the first term, it is plain that "its co-efficient in any term will be equal to the number of terms that precede that term." Therefore, in the last term x, you must have $\overline{n-1} \times b$, so that x must be equal to $a + \overline{n-1} \times b$. And the sum of all the terms being $\overline{a+x} \times \frac{n}{2}$, it will also be equal to $\frac{2an + n^2b - nb}{2}$, or to $a + \frac{nb-b}{2} \times n$. Thus, for example, the series $1 + 2 + 3 + 4 + 5$, &c. continued to a hundred, must be equal to $\frac{2 \times 100 + 10000 - 100}{2} = 5050$.

If a series have (0) nothing for its first term, then "its sum shall be equal to half the product of the last term multiplied by the number of terms." For then, a being $= 0$, the sum of the terms, which is in general $\overline{a+x} \times \frac{n}{2}$, will in this case be $\frac{nx}{2}$. From which it is evident, that "the sum of any number of arithmetical proportionals beginning from nothing, is equal to half the sum of as many terms each equal to the greatest term." Thus,

$$0+1+2+3+4+5+6+7+8+9$$
$$= \frac{9+9+9+9+9+9+9+9+9+9}{2} = \frac{10 \times 9}{2} = 45.$$

"If of four quantities the quotient of the first and second be equal to the quotient of the third and fourth, then those quantities are said to be in geometrical proportion." Such are the numbers 2, 6, 4, 12; and the quantities a, ar, b, br; which are expressed after this manner;

$$2 : 6 :: 4 : 12.$$
$$a : ar :: b : br.$$

And you read them by saying, As 2 is to 6, so is 4 to 12; or as a is to ar, so is b to br.

In four quantities geometrically proportional, "the product of the extremes is equal to the product of the middle terms." Thus, $a \times br = ar \times b$. And, if it is required to find a fourth proportional to any three given quantities, "multiply the second by the third, and divide their product by the first, the quotient shall give the fourth proportional required." Thus, to find a fourth proportional to a, ar, and b, I multiply ar by b, and divide the product arb by the first term a, the quotient br is the fourth proportional required.

When a series of quantities increase by one common multiplicator, or decrease by one common divisor, they are said to be in "geometrical proportion continued."

As, a, ar, ar^2, ar^3, ar^4, ar^5, &c. or, a, $\frac{a}{r}$, $\frac{a}{r^2}$, $\frac{a}{r_3}$, $\frac{a}{r^4}$, $\frac{a}{r^5}$, &c.

The common multiplier or divisor is called their "common ratio."

In such a series, "the product of the first and last is always equal to the product of the second and last but one, or to the product of any two terms equally remote from the extremes." In the series a, ar, ar^2, ar^3, &c. if y be the last term, then shall the four last terms of the series be y, $\frac{y}{r}$, $\frac{y}{r^2}$, $\frac{y}{r^3}$; now it is plain that $a \times y = ar \times \frac{y}{r} = ar^2 \times \frac{y}{r^2} = ar^3 \times \frac{y}{r^3}$, &c.

"The sum of a series of geometrical proportionals wanting the first term, is equal to the sum of all but the last term multiplied by the common ratio."

For $ar + ar^2 + ar^3$, &c. $+ \frac{y}{r^3} + \frac{y}{r^2} + \frac{y}{r} + y =$

$r \times a + ar + ar^2$, &c. $+ \frac{y}{r^4} + \frac{y}{r^3} + \frac{y}{r^2} + \frac{y}{r}$.

Therefore, if s be the sum of the series, $s - a$ will be equal to $\overline{s-y} \times r$; that is, $s - a = sr - yr$, or $sr - s = yr - a$, and $s = \frac{yr-a}{r-1}$.*

Since the exponent of r is always increasing from the second term, if the number of terms be n in the last term its exponent will be $n - 1$. Therefore $y = ar^{n-1}$; and $yr = ar^{n-1+1} = ar^n$; and $s = \left(\frac{yr-a}{r-1}\right) = \frac{ar^n - a}{r-1}$. So that having the first term of the series, the number of the terms, and the common ratio, you may easily find the sum of all the terms.

If it is a decreasing series, whose sum is to be found as of $y + \frac{y}{r} + \frac{y}{r^2} + \frac{y}{r^3}$, &c. $+ ar^3 + ar^2 + ar + a$, and the number of the terms be supposed infinite, then shall a, the last term, be equal to nothing. For, because n, and consequently r^{n-1}, is infinite, $a = \frac{y}{r^n - 1} = 0$. The sum of such a series $s = \frac{yr}{r-1}$; which is a finite sum, though the number of terms be infinite. Thus,

$$1 + \tfrac{1}{2} + \tfrac{1}{4} + \tfrac{1}{8} + \tfrac{1}{16}, + \text{ &c.} = \frac{1 \times 2}{2-1} = 2.$$

and $1 + \frac{1}{3} + \frac{1}{9} + \frac{1}{27} + \frac{1}{81} + \text{ &c.} = \frac{1 \times 3}{3-1} = \frac{3}{2}$.

OF EQUATIONS.

Definit. 1. An Equation is a proposition asserting the equality of two quantities, and is expressed by placing the sign = between them.

Definit. 2. Equations containing only one unknown quantity and its powers, are divided into orders, according to the highest power of the unknown quantity to be found in any of its terms.

* See the Rules under the next general head.

If the highest power of the unknown quantity in any term be the 1st, 2d, 3d, &c. The equation is called Simple, Quadrat, Cubic, &c.

But the exponents of the unknown quantities are supposed to be integers, and the equation is supposed to be cleared of fractions, in which the unknown quantity, or any of its powers, enter the denominators. Thus, $x + a = \frac{3x - b}{c}$ is a simple equation; $3x - \frac{5}{2x} = 12$, when cleared of the fraction by multiplying both sides by $2x$, becomes $6x^2 - 5 = 24x$ a quadratic; $x^3 - 2x^4 = x^6 - 20$ is an equation of the sixth order, &c.

To resolve an equation is to find the value of the unknown term in known terms.

OF SIMPLE EQUATIONS, AND THEIR RESOLUTIONS.

Rule 1. Any quantity may be transposed from one side of an equation to the other, by changing its sign.

Thus, if $3x - 10 = 2x + 5$
Then, $3x - 2x = 10 + 5$ or $x = 15$
Thus also, $5x + b = a + 2x$
By transp. $3x = a - b$.

For equal quantities are thus added to or subtracted from both sides.

Corol. The signs of all the terms of an equation may be changed into the contrary signs, and it will continue to be true.

Rule 2. Any quantity by which the unknown quantity is multiplied may be taken away, by dividing all the other quantities of the equation by it.

Thus, if $ax = b$

$$x = \frac{b}{a}$$

Also, if $mx + nb = am$

$$x + \frac{nb}{m} = a.$$

For if equal quantities are divided by the same quantity, the quotients are equal.

Rule 3. If a term of an equation is fractional, its denominator may be taken away by multiplying all the other terms by it.

Thus, if $\frac{x}{a} = b + c$ Also, if $a - \frac{b}{x} = c$

$x = ab + ac$ $ax - b = cx$

And by trans. $ax - cx = b$

And by div. $x = \frac{b}{a - c}$.

For, if all the terms of the equation are multiplied by the same quantity, the quantities on each side will be equal.

Corol. If any quantity be found on both sides of the equation, with the same sign, it may be taken away from both.

Also, if all the terms in the equation are multiplied or divided by the same quantity, it may be taken out of them all.

EXAMPLE.

If $3x + a = a + b$, then $3x = b$.
If $2ax + 3ab = ma + a^2$, then $2x + 3b = m + a$.
If $\frac{x}{3} - \frac{4}{3} = \frac{16}{3}$, then $x - 4 = 16$.

By these rules the unknown term may be separated from the known, and the equation is resolved.

Examples of simple equations resolved by these rules.

If $3x + 5 = x + 9$
$2x = 4$
$x = \frac{4}{2} = 2.$

If $5x - \frac{5x}{2} + 12 = \frac{4x}{3} + 26$
$5x - \frac{5x}{2} - \frac{4x}{3} = 26 - 12 = 14$
$30x - 15x - 8x = 84.$
Or $7x = 84$
$x = \frac{84}{7} = 12.$

If $\frac{5}{x} + \frac{9}{4} = 16$
$\frac{20}{x} + 9 = 64$
$20 + 9x = 64x$
$20 = 64x - 9x = 55x$
$x = \frac{20}{55} = \frac{4}{11}.$

SOLUTION OF QUESTIONS PRODUCING SIMPLE EQUATIONS.

General Rule. The unknown quantities in the question proposed must be expressed by letters, and the relations of the known and unknown quantities contained in it, or the conditions of it, as they are called, must be expressed by equations. These equations being resolved, give the answer to the question.

For example, if the question is concerning two numbers, they may be called x and y, and the conditions from which they are to be investigated must be expressible by equations.

Thus, if it be required that the sum of two numbers sought be 60, that condition is expressed thus: $x + y = 60$
If their difference must be 24, then $x - y = 24$
If their product is 1640, then $xy = 1640$
If their quotient must be 6, then $\frac{x}{y} = 6.$

Case 1. When there is only one unknown quantity to be found.

Rule. An equation involving the unknown quantity must be deduced from the question; and it is obvious,

that, when there is only one unknown quantity, there must be only one independent equation contained in the question; for any other would be unnecessary, and might be contradictory to the former.

Ex. 1. To find a number, to which if there be added a half, a third part, and a fourth part of itself, the sum will be 50.

Let it be z: then half of it is $\frac{z}{2}$, a third of it is $\frac{z}{3}$, &c.

Therefore, $z + \frac{z}{2} + \frac{z}{3} + \frac{z}{4} = 50$

$$24z + 12z + 8z + 6z = 1200$$
$$50z = 1200$$
$$z = 24.$$

Case II. When there are two unknown quantities.

Rule. Two independent equations involving the two unknown quantities, must be derived from the question. A value of one of the unknown quantities must be derived from each of the equations; and these two values being put equal to each other, a new equation will arise, involving only one unknown quantity.

Ex. 2. Two persons, A and B, were talking of their ages; says A to B, Seven years ago I was just three times as old as you were, and seven years hence I shall be just twice as old as you will be. I demand their present ages.

Let the ages of A and B be x and y, then seven years ago their ages were $x - 7$ and $y - 7$; and seven years hence they will be $x + 7$ and $y + 7$; therefore

$$x - 7 = \overline{y - 7} \times 3 = 3y - 21$$
$$x + 7 = y + 7 \times 2 = 2y + 14$$
$$x = 3y - 21 + 7 = 3y - 14$$
$$x = 2y + 14 - 7 = 2y + 7$$

Therefore $3y - 14 = 2y + 7$

$y = 21$, and

$x = 49$

Ex. 3. A gentleman distributing money among some poor people, found he wanted 10s. to be able to give 5s. to each; therefore he gives each 4s. only, and finds he has 5s. left. To find the number of shillings and poor people.

If any question such as this, in which there are two quantities sought, can be resolved by means of one letter, the solution is in general more simple than when two are employed. There must be, however, two independent conditions; one of which is used in the notation of one of the unknown quantities, and the other gives an equation.

Let the number of poor be z, then the number of shillings will be $5z - 10$, and also $4z + 5$; therefore,

$5z - 10 = 4z + 5$

$z = 15$, equal the number of poor, of course the number of shillings is 65.

Case III. When there are three or more unknown quantities.

Rule. When there are three unknown quantities, there must be three independent equations arising from the question; and from each of these a value of one of the unknown quantities must be obtained. By comparing these three values, two equations will arise, involving only two unknown quantities; and in like manner may the rule be extended to such questions as contain four or more unknown quantities. Hence it may be inferred, that when just as many independent equations may be derived from a question as there are unknown quantities in it, these quantities may be found by the resolution of equations.

Ex. 4. To find three numbers, so that the first with half the other two, the second with one third of the other two, and the third with one fourth of the other two, may each be equal to 34.

Let the numbers be x, y, z, and the equations will be

$$x + \frac{y + z}{2} = 34$$

$$y + \frac{x + z}{3} = 34$$

$$z + \frac{x + y}{4} = 34;$$ then, by the first equation

$$x = \frac{68 - y - z}{2};$$ and by the second

$x = 102 - 3y - z$; and by the third

$x = 136 - 4z - y$; therefore

$$\frac{68 - y - z}{2} = 102 - 3y - z$$

$$y = \frac{136 - z}{5};$$ and by the two latter equations

$$y = \frac{3z - 34}{2},$$ therefore,

$$\frac{3z - 34}{2} = \frac{136 - z}{5}$$

$$15z - 170 = 272 - 2z$$
$$17z = 442, \text{ or } z = 26$$
$$y = 22, \text{ and } x = 10.$$

On many occasions, by particular contrivances, the operations by the preceding rules may be much abridged. This, however, must be left to the skill and practice of the learner. A few examples are the following.

1. It is often easy to employ fewer letters than there are unknown quantities, by expressing some of them from a simple relation to others contained in the conditions of the question.

2. Sometimes it is convenient to express by letters, not the unknown quantities themselves, but some other quantities connected with them, as their sum, difference, &c. from which they may be easily derived.

3. In the operation, also, circumstances will suggest a more easy road than that pointed out by the general rules. Two of the original equations may be added together, or may be subtracted; sometimes they must be previously multiplied by some quantity, to render such addition or subtraction effectual, in exterminating one of the unknown quantities, or otherwise promoting the solution. Substitutions may be made of the values of quantities, in place of quantities themselves; and various other such contrivances may be used, which will render the solution much less complicated.

GENERAL SOLUTION OF PROBLEMS.

In the solutions of the questions in the preceding part, the given quantities, being numbers, disappear in the last conclusion, so that no general rules for like cases can be deduced from them. But if letters are used to denote the known quantities, as well as the unknown, a general solution may be obtained, because, during the whole course of the operation, they retain their original form. Hence also the connection of the quantities will appear in such a manner as to discover the necessary limitations of the data, when there are any, which is necessary to the perfect solution of a problem.

Ex. 1. To find two numbers, of which the sum and difference are given.

Let s be the sum given, and d the given difference. Also, let x and y be the two numbers sought.

$$\begin{aligned} x+y &= s \\ x-y &= d \\ \text{Whence } &\begin{cases} x = s-y \\ x = d+y \end{cases} \\ d+y &= s-y \\ 2y &= s-d \\ y &= \frac{s-d}{2} \\ \text{And } x &= \frac{s+d}{2}. \end{aligned}$$

Thus, let the given sum be 100, and the difference 24.

$$\text{Then } x = \left(\frac{s+d}{2} = \frac{124}{2} = \right) 62$$

$$\text{and } y = \left(\frac{s-d}{2} = \frac{76}{2} = \right) 38$$

Equations are either pure or adfected.

Definit. 1. A pure equation is that in which only one power of the unknown quantity is found.

2. An adfected equation is that in which different powers of the unknown quantity are found in the several terms. Thus,

$a^2 + ax^2 = b^3$, $ax^2 - b^2 = m^2 + x^2$, are pure equations.

$x^2 - ax = b^2$, $x^3 + x^2 = 17$, are adfected equations.

SOLUTION OF PURE EQUATIONS.

Rule. Make the power of the unknown quantity to stand alone by the rules formerly given, and then extract the root of the same denomination out of both sides, which will give the value of the unknown quantity.

EXAMPLES.

If $a^2 + ax^2 = b^3$

$$\begin{aligned} ax^2 &= b^3 - a^2 \\ x^2 &= \frac{b^3 - a^2}{a} \\ x &= \sqrt{\frac{b^3 - a^2}{a}} \end{aligned}$$

$ax^m - b = x^m - c$

$$\begin{aligned} ax^m - x^m &= b - c \\ x^m &= \frac{b - c}{a - 1} \\ x &= \sqrt[m]{\frac{b - c}{a - 1}} \end{aligned}$$

SOLUTION OF ADFECTED QUADRATIC EQUATIONS.

An adfected quadratic equation, commonly called a quadratic, involves the unknown quantity itself, and also its square:

Rule 1. Transpose all the terms involving the unknown quantity to one side, and the known terms to the other; and so that the term containing the square of the unknown quantity may be positive.

2. If the square of the unknown quantity is multiplied by any co-efficient, all the terms of the equation are to be divided by it, so that the co-efficient of the square of the unknown quantity may be 1.

3. Add to both sides the square of half the co-efficient of the unknown quantity, and the side of the equation involving the unknown quantity will be a complete square.

4. Extract the square root from both sides of the equation, and by transposing the above mentioned half co-efficient, a value of the unknown quantity is obtained in known terms.

The reason of this rule is manifest from the composition of the square of a binomial, for it consists of the squares of the two parts, and twice the product of the two parts.

The different forms of quadratic equations, expressed in general terms, being reduced by the first and second parts of the rule, are these:

1. $x^2 + ax = b^2$
2. $x^2 - ax = b^2$
3. $x^2 - ax = -b^2$

Case 1. $x^2 + ax = b^2$

$$\begin{aligned} x^2 + ax + \frac{a^2}{4} &= b^2 + \frac{a^2}{4} \\ x + \frac{a}{2} &= \pm \sqrt{b^2 + \frac{a^2}{4}} \\ x &= \pm \sqrt{b^2 + \frac{a^2}{4}} - \frac{a}{2} \end{aligned}$$

Case 2. $x^2 - ax = b^2$

$$\begin{aligned} x^2 - ax + \frac{a^2}{4} &= b^2 + \frac{a^2}{4} \\ x - \frac{a}{2} &= \pm \sqrt{b^2 + \frac{a^2}{4}} \\ x &= \frac{a}{2} \pm \sqrt{b^2 + \frac{a^2}{4}} \end{aligned}$$

Case 3. $x^2 - ax = -b^2$

$$\begin{aligned} x^2 - a^2 + \frac{a^2}{4} &= \frac{a^2}{4} - b^2 \\ x - \frac{a}{2} &= \pm \sqrt{\frac{a^2}{4} - b^2} \\ x &= \frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b^2}. \end{aligned}$$

1. Every quadratic equation will have two roots, except such of the third form whose roots become impossible.

2. In the two first forms, one of the roots must be positive, and the other negative.

3. In the third form, if $\frac{a^2}{4}$, or the square of half of the co-efficient of the unknown quantity, be greater than b^2, the known quantity, the two roots will be positive. If $\frac{a^2}{4}$ be equal to b^2, the two roots become equal; but if $\frac{a^2}{4}$ is less than b^2, the quantity under the radical sign becomes negative, and the two roots are impossible.

4. If the equation express the relation of magnitudes abstractly considered, where a contrariety cannot be supposed to take place, the negative roots cannot be of use, or rather there are no such roots; for then a negative quantity by itself is unintelligible, and therefore the square root of a positive quantity must be positive only.

SOLUTION OF QUESTIONS PRODUCING QUADRATIC EQUATIONS.

The expression of the conditions of the question by equations, or the stating of it, and the reduction likewise of these equations, till we arrive at a quadratic equation, involving only one unknown quantity and its square, are effected by the same rules which were given for the solution of simple equations.

Ex. 1. One lays out a certain sum of money in goods, which he sold again for 24*l.* and gained as much per cent. as the goods cost him: I demand what they cost him?

If the money laid out be y
The gain will be $24 - y$
But this gain is $(y : 24 - y :: 100) \left\{ \frac{2400 - 100y}{y} \right.$ per cent.
Therefore by question $\left\{ y = \frac{2400 - 100y}{y} \right.$
And by mult. and tr. $y^2 + 100y = 2400$
Completing the square $\left\{ \begin{array}{l} y^2 + 100y + 50^2 = 2400 \\ \quad + 2500 = 4900 \end{array} \right.$
Extract the root $y + 50 = \pm\sqrt{4900} = 70$
Trans. $y = \pm 70 - 50 = 20$, or -120.

The answer is 20*l.* which succeeds. The other root, -120, has no place in this example, a negative number being here unintelligible.

To find two numbers whose sum is 100, and whose product is 2059.

Ex. 2. Let the given sum $100 = a$, the product $2059 = b$, and let one of the numbers sought be x, the other will be $a - x$. Their product is $ax - x^2$.

Therefore $ax - x^2 = b$, or $x^2 - ax = -b$
Compl. the sq. $x^2 - ax + \frac{a^2}{4} = \frac{a^2}{4} - b$.

Ext. $\sqrt{\quad}$ $x - \frac{a}{2} = \pm\sqrt{\frac{a^2}{4} - b}$
Transp. $x = \frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b}$
And the other number $\left\{ a - x = \frac{a}{2} \mp \sqrt{\frac{a^2}{4} - b}. \right.$

By inserting numbers, $x = 71$ or 29, and $a - x = 29$ or 71, so that the two numbers sought are 71 and 29.

Here it is to be observed, that b must not be greater than $\frac{a^2}{4}$, else the roots of the equation would be impossible; that is, the given product must not be greater than the square of half the given sum of the numbers sought. This limitation can easily be shown from other principles; for the greatest possible product of two parts into which any number may be divided, is, when each of them is a half of it. If b be equal to $\frac{a^2}{4}$, there is only one solution, and $x = \frac{a}{2}$, also $a - x = \frac{a}{2}$.

OF INDETERMINATE PROBLEMS.

It may be observed, that if there are more unknown quantities in a question than equations, by which their relations are expressed, it is indetermined. In other circumstances, such problems are resolved by various methods, not to be comprehended in general rules.

Ex. 1. To divide a given square number into two parts, each of which shall be a square number.

There are two quantities sought in this question, and there is only one equation expressing their relation; but it is required also that they may be rational, which circumstance cannot be expressed by an equation; another condition therefore must be assumed, in such a manner as to obtain a solution in rational numbers.

Let the given square be a^2; let one of the squares sought be x^2, the other is $a^2 - x^2$. Let $rx - a$ also be a side of the last square, therefore

$r^2x^2 - 2rxa + a^2 = a^2 - x^2$
By transp. $r^2x^2 + x^2 = 2rxa$
Divide by x $r^2x + x = 2ra$
Therefore $x = \frac{2ra}{r^2 + 1}$
And $rx - a = \frac{2r^2a}{r^2 + 1} - a = \frac{r^2 - 1}{r^2 + 1} a.$

Let r therefore be assumed at pleasure, and $\frac{2ra}{r^2 + 1}$, $\frac{r^2 - 1}{r^2 + 1} a$, which must always be rational, will be the sides of the two squares required.

Thus, if $a^2 = 100$; then, if $r = 3$, the sides of the two squares are 6 and 8, for $36 + 64 = 100$.

Also, let $a^2 = 64$. Then, if $r = 2$, the sides of the

squares are $\frac{32}{5}$ and $\frac{24}{5}$; and $\frac{1024}{25} + \frac{576}{25} = \frac{1600}{25} = 64$.

The reason of the assumption of $rx - a$ as a side of the square $a^2 - x^2$, is, that being squared and put equal to this last, the equation manifestly will be simple, and the root of such an equation is always rational.

Ex. 2. To find two square numbers whose difference is given.

Let x^2 and y^2 be the square numbers, and a their difference.

$$\text{Put } \frac{z+v}{2} = x, \text{ and } \frac{z-v}{2} = y$$

$$\frac{z^2 + 2zv + v^2}{4} = x^2$$

$$\frac{z^2 - 2zv + v^2}{4} = y^2$$

$$zv = x^2 - y^2 = a.$$

If x and y are required only to be rational, then take v at pleasure, and $x = \frac{a}{v}$, whence x and y are known.

But if x and y are required to be whole numbers, take for z and v any two factors that produce a, and are both even or both odd numbers. And this is possible only where a is either an odd number greater than 1, or a number divisible by 4.

Then $\frac{z+v}{2}$ and $\frac{z-v}{2}$ are the numbers sought.

For the product of two odd numbers is odd, and that of two even numbers is divisible by 4. Also if z and v are both odd or both even, $\frac{z+v}{2}$ and $\frac{z-v}{2}$ must be integers.

Ex. 1. If $a = 27$, take $v = 1$, then $z = 27$; and the squares are 196 and 169. Or z may be 9, and $v = 3$, and then the squares are 36 and 9.

2. If $a = 12$, take $v = 2$, and $z = 6$; and the squares are 16 and 4.

OF THE ORIGIN AND COMPOSITION OF EQUATIONS; AND OF THE SIGNS AND CO-EFFICIENTS OF THEIR TERMS.

The higher orders of equations, and their general affections, are best investigated by considering their origin from the combination of inferior equations.

In this general method, all the terms of any equation are brought to one side, and the equation is expressed by making them equal to 0. Therefore, if a root of the equation be inserted instead of (x) the unknown quantity, the positive terms will be equal to the negative, and the whole must be equal to 0.

Definit. When any equation is put into this form, the term in which (x) the unknown quantity is of the highest power is made the first, that in which the index of x is less by 1 is the second, and so on, till the last into which the unknown quantity does not enter, and which is called the absolute term.

Prop. I. If any number of equations be multiplied together, an equation will be produced of which the dimension is equal to the sum of the dimensions of the equations multiplied.

If any number of simple equations be multiplied together, as $x - a = 0$, $x - b = 0$, $x - c = 0$, &c. the product will be an equation of a dimension, containing as many units as there are simple equations. In like manner, if higher equations are multiplied together, as a cubic and a quadratic, one of the fifth order is produced, and so on.

Conversely. An equation of any dimension is considered as compounded either of simple equations, or of other such that the sum of their dimensions is equal to the dimension of the given one. By the resolution of equations these inferior equations are discovered, and by investigating the component simple equations, the roots of any higher equation are found.

Cor. 1. An equation admits of as many solutions, or has as many roots, as there are simple equations which compose it.

Cor. 2. And conversely no equation can have more roots than it has dimensions.

Cor. 3. Imaginary or impossible roots must enter an equation by pairs; for they arise from quadratics, in which both the roots are such. And an equation of an even dimension may have all its roots, or any even number of them, impossible; but an equation of an odd dimension must at least have one possible root.

Cor. 4. The roots are either positive or negative, according as the roots of the simple equations, from which they are produced, are positive or negative.

Cor. 5. When one root of an equation is discovered, one of the simple equations is found, from which the given one is compounded. The given equation, therefore, being divided by this simple equation, will give an equation of a dimension lower by 1.

Prop. II. To explain the general properties of the signs and co-efficients of the terms of an equation.

Let $x - a = 0$, $x - b = 0$, $x - c = 0$, $x - d = 0$, &c. be simple equations, of which the roots are any positive quantities $+a$, $+b$, $+c$, $+d$, &c. and let $x + m = 0$, $x + n = 0$, &c. be simple equations, of which the roots are any negative quantities $-m$, $-n$, and let any number of these equations be multiplied together, as in the following table:

$$\begin{array}{l} x - a = 0 \\ \times\ x - b = 0 \\ \hline = x^2 - ax \\ \quad - bx + ab \end{array} \Big\} = 0, \text{ a Quadratic.}$$

$$\begin{array}{l} \times\ x - c = 0 \\ \hline = x^3 - a \\ \quad - b \\ \quad - c \end{array} \Big\} \times \begin{array}{l} x^2 + ab \\ \quad + ac \\ \quad + bc \end{array} \Big\} \times x - abc = 0, \text{ a Cubic.}$$

$$\begin{array}{l} \times\ x - m = 0 \\ \hline = x^4 - a \\ \quad - b \\ \quad - c \\ \quad + m \end{array} \Big\} \times \begin{array}{l} x^3 + ab \\ \quad + ac \\ \quad + bc \\ \quad - am \\ \quad - bm \\ \quad - cm \end{array} \Big\} \times \begin{array}{l} x^2 - abc \\ \quad + abm \\ \quad + acm \\ \quad + bcm \end{array} \Big\} \times x - abcm = 0, \text{ a Biquadratic.}$$

From this table it is plain,

1. That in a complete equation the number of terms is always greater by unit than the dimension of the equation.

2. The co-efficient of the first term is 1.

The co-efficient of the second term is the sum of all the roots (a, b, c, m, &c.) with their signs changed.

The co-efficient of the third term is the sum of all the products that can be made by multiplying any two of the roots together.

The co-efficient of the fourth term is the sum of all the products which can be made by multiplying together any three of the roots with their signs changed; and so of others.

The last term is the product of all the roots, with their signs changed.

3. From induction it appears, that in any equation, the terms being regularly arranged as in the preceding example, there are as many positive roots as there are changes in the signs of the terms from + to —, and from — to +; and the remaining roots are negative. The rule also may be demonstrated.

Note. The impossible roots in this rule are supposed to be either positive or negative.

Cor. If a term of an equation is wanting, the positive and negative parts of its co-efficient must then be equal. If there is no absolute term, some of the roots $= 0$, and the equation may be depressed by dividing all the terms by the lowest power of the unknown quantity in any of them. In this case also, $x - 0 = 0$, $x - 0 = 0$, &c. may be considered as so many of the component simple equations, by which the given equation being divided, it will be depressed so many degrees.

OF THE TRANSFORMATION OF EQUATIONS.

Prop. I. The affirmative roots of an equation become negative, and the negative become affirmative, by changing the signs of the alternate terms, beginning with the second.

Thus the roots of the equation $x^4 - x^3 - 19x^2 + 49x - 30 = 0$, are $+1$, $+2$, $+3$, -5, whereas the roots of the equation $x^4 + x^3 - 19x^2 - 49x - 30 = 0$, are -1, -2, -3, $+5$.

The reason of this is derived from the composition of the co-efficients of these terms, which consist of combinations of odd numbers of the roots, as explained in the preceding head.

Prop. II. An equation may be transformed into another that shall have its roots greater or less than the roots of the given equation by some given difference.

Let e be the given difference; then $y = x \pm e$, and $x = y \mp e$; and if for x and its powers in the given equation, $y \mp e$ and its powers be inserted, a new equation will arise, in which the unknown quantity is y, and its value will be $x \pm e$.

Let the equation proposed be $x^3 - px^2 + qx - r = 0$, of which the roots must be diminished by e. By inserting for x and its powers $y + e$ and its powers, the equation required is,

$$\left.\begin{array}{rrrr} y^3 & + 3ey^2 & + 3e^2y & + e^3 \\ & - py^2 & - 2pey & - pe^2 \\ & & + qy & + qe \\ & & & - r \end{array}\right\} = 0.$$

Cor. 1. The use of this transformation is to take away the second, or any other intermediate term; for as the co-efficients of all the terms of the transformed equation, except the first, involve the powers of e, and known quantities only, by putting the co-efficient of any term equal to 0, and resolving that equation, a value of e may be determined, which being substituted, will make that term to vanish.

Thus let the co-efficient $3e - p = 0$, and $e = \frac{1}{3}p$, which being substituted for e, the new equation will want the second term. And universally the co-efficient of the first term of an equation of n dimensions being 1, the second term may be taken away, by supposing $x = y \pm \frac{1}{n}p$.

Cor. 2. The second term may be taken away by the solution of a simple equation, the third by the solution of a quadratic, and so on.

Prop. III. An equation may be transformed into another, of which the roots shall be equal to the roots of the given equation, multiplied or divided by a given quantity.

Let $y = xe$, or $y = \frac{x}{e}$.

Then substitute for x and its powers, $\frac{y}{e}$ or ye and its powers, and the new equation will have the property required.

Cor. 1. An equation, in which the co-efficient of the first term is any known quantity, as a, may thus be transformed into another, in which the co-efficient of the first term shall be unit. Thus, let the equation be $ax^3 - px^2 + qx - r = 0$.

Suppose $y = ax$, or $x = \frac{y}{a}$, and for x and its powers insert $\frac{y}{a}$ and its powers, and the equation becomes $\frac{y^3}{a^2} - \frac{py^2}{a^2} + \frac{qy}{a} - r = 0$, or $y^3 - py^2 + qay - a^2r = 0$.

Cor. 2. If there are fractions in an equation, they may be taken away, by multiplying the equation by the denominators, and by this proposition the equation may then be transformed into another, without fractions, in which the co-efficient of the first term is 1. In like manner may a surd co-efficient be taken away in certain cases.

Cor. 3. Hence also, if the co-efficient of the second term of a cubic equation is not divisible by 3, the fractions thence arising in the transformed equation wanting the second term, may be taken away by the preceding corollary. But the second term also may be taken away, so that there shall be no such fractions in the transformed equation, by supposing $x = \frac{z \mp p}{3}$, $\pm p$ being the co-efficient of the second term of the given equation. And if the equation $ax^3 - px^2 + qx - r = 0$, be given, in which p is not divisible by 3, by supposing $x = \frac{z + p}{3a}$, the transformed equation reduced is $z^3 - 3p^2 + 9aq \times z - 2p^3 + 9apq - 27a^2r = 0$; wanting the second term.

having 1 for the co-efficient of the first term, and the co-efficients of the other terms being all integers, the co-efficients of the given equation being also supposed integers.

General Corollary to Prop. I, II, III.

If the roots of any of these transformed equations be found by any method, the roots of the original equation, from which they were derived, will easily be found from the simple equations expressing their relation. Thus, if 8 is found to be a root of the transformed equation $z^3 + 23z - 696 = 0$. Since $x = \frac{z+2}{5}$, the corresponding root of the given equation $5x^3 - 6x^2 + 7x - 30 = 0$, must be $\frac{8+2}{5} = 2$. It is to be observed also, that the reasoning in Prop. II. and III. and the Corollaries, may be extended to any order of equations, though in them it is applied chiefly to cubics.

From the preceding principles and operations, rules may be derived for resolving equations of all orders.

ALGENEB, a fixed star of the second magnitude, on the right shoulder of the constellation Perseus.

ALGOL, the name of a fixed star of the second magnitude in the constellation Perseus, otherwise called Medusa's head.

This star has been subject to singular variations, appearing at different times of different magnitudes, from the fourth to the second, which is its usual appearance. It has been conjectured that the cause of this variation is owing either to the interposition of a large body revolving round Algol, or to some motion of its own, in consequence of which, part of its body, covered with spots, is periodically turned toward the earth. The period of variation is said to be 2d. 20h. 49′ 2″.

ALGOMEIZA, a name given to the star Procyon.

ALGOR, among medical writers, a term used to denote an unusual coldness or chillness in any part of the body.

ALGORAB, a fixed star of the third magnitude, in the right wing of Corvus.

ALGUAZIL, in the Spanish policy, an officer whose business it is to see the decrees of a judge executed.

ALHABOR, among the Arabians, is the star which we call Sirius.

ALHIRTO, a fixed star of the third magnitude, in the constellation Capricorn. It is sometimes called *rostrum gallinæ*. Near this star, in the year 1600, appeared a new star, which lasted 21 years, and then disappeared again.

ALIAS, in law, a second or further writ issued from the courts of Westminster after a *capias*, &c. has been sued out without effect.

Alias Dictus, the legal description of a person known by two or more names.

ALIBI, denotes the absence of the accused from the place where he is charged to have committed the crime.

ALIDES, among the Mahometans, a designation given to the descendants of Ali; between whom and the Ommiades there was a warm dispute about the kaliphate.

ALIEN, in law, a person born in a strange country, not within the king's allegiance, in contradistinction from a denizen, or a natural subject. See Denizen.

An alien is incapable of inheriting lands in England, till naturalized by an act of parliament. No alien is entitled to vote in the choice of members of parliament, nor can enjoy an office, or be returned on any jury, unless where an alien is party in a cause; and then the inquest of jurors shall be one half natives and the other aliens.

The issue of an English woman, by an alien, born abroad, is an alien in law. But if an Englishman, living beyond sea, marry a wife there, and have children born abroad, they are denizens, and shall be heirs to their father.

Aliens can have no heirs, strictly so called, because they have not in them any heritable blood; yet natural born subjects may inherit as heirs to their ancestors, even though their ancestors were aliens.

If an alien is made a denizen by letters patent, and then purchases lands, his son before his denization shall not inherit; but a son born afterward may inherit, even though the elder brother be living. Blacks.

Every foreign seaman serving on board an English ship two years in time of war is naturalized.

Masters of ships arriving from foreign parts are to give notice at every port of the number and names of all foreigners on board, under a penalty of 10*l.* for each alien whose name is omitted; 33 Geo. III. c. 4. And by the 42d Geo. III. c. 22, commonly called the alien bill, his majesty may issue a proclamation ordering aliens out of the kingdom; and in case of disobedience, the alien for the first offence shall suffer imprisonment for one month, and for twelve months for a second offence, being liable to transportation for life for the third. Secretaries of state may grant warrants for conducting such aliens out of the kingdom as they apprehend will not pay due obedience to the proclamation.

Alien duty, an impost laid on all goods imported by aliens, over and above the customs paid for such goods imported by British and on British bottoms.

Alien priories, a kind of inferior monasteries, formerly very numerous in England, and so called from their belonging to foreign abbies.

ALIENABLE, denotes something that may be alienated.

All estates are alienable, except those in tail and for life: a bond too, with condition not to alien, is said to be good.

ALIENATION, in law, denotes the act of making over a man's property in lands, tenements, &c. to another person.

To *alien* or *alienate* in fee, is to sell or convey the fee simple of lands, &c.

Alienation, in mortmain, is making over lands, tenements, &c. to a body politic, or to a religious house, for which the king's license must first be obtained, otherwise the lands, &c. alienated will be forfeited. See Mortmain.

Alienation of crown lands is always supposed to be made under a faculty of perpetual redemption.

A perpetual copy hold is also a kind of alienation.

Alienation, in Roman antiquity, was used for a father's discarding a son in his own life time.

Alienation *office*, is that to which are carried all writs of covenants and entry upon which fines are levied, in order to have fines for alienation set upon them.

ALIMENT, among physicians, denotes whatever is capable of nourishing the human body. Aliment is either animal or vegetable, of an attenuating or incrassating nature; and with respect to the taste, is sweet, fat, acid, astringent, salsuginous, bitter, and acrid.

ALIMENTARY DUCT, a name by which some call the intestines, on account of the food passing through them. See ANATOMY.

Alimentary duct is sometimes also used for the thoracic duct.

ALIMENTARY CHILDREN, in Roman antiquity, an appellation given to those educated in houses not unlike our hospitals, erected for that purpose. There were likewise alimentary girls, who owed their maintenance to the bounty of several empresses, as the boys did theirs to that of the emperors.

ALIMENTARY LAW, among the same people, that whereby children were obliged to maintain their aged parents.

ALIMONY, in law, denotes the maintenance sued for by a wife, in case of separation from her husband, wherein she is neither chargeable with elopement nor adultery.

Anciently this was recoverable only in the spiritual courts, but at present may be obtained in chancery.

ALIPILARIUS, or ALIPILUS, in Roman antiquity, a servant belonging to the baths, whose business it was, by means of waxen plasters, and an instrument called volsella, to take off the hairs from the arm pits, and even arms, legs, &c. this being deemed a point of cleanliness.

ALIQUANT *parts*, in arithmetic, those which will not divide or measure the whole number exactly. Thus, 7 is an aliquant part of 16, for twice 7 wants 2 of 16, and three times 7 exceeds 16 by 5.

ALIQUOT *part*, is such part of a number as will divide and measure it exactly, without any remainder. For instance, 2 is an aliquot part of 4, 3 of 9, and 4 of 16.

To find all the aliquot parts of a number, divide it by its least divisor, and the quotient by its least divisor, until you get a quotient not further divisible, and you will have all the prime divisors or aliquot parts of that number. Thus, 60 divided by 2, gives the quotient 30, which divided by 2 gives 15, and 15 divided by 3 gives the indivisible quotient 5. Hence the prime aliquot parts are 1, 2, 3, 5; and by multiplying any two or three of these together, you will find the compound aliquot parts, *viz.* 4, 6, 10, 12, 15, 20, 30.

Aliquot parts must not be confounded with commensurable ones; for though the former are all commensurable, yet these are not always aliquot parts: thus 4 is commensurable with 6, but is not an aliquot part of it.

ALISMA, water plantain, a genus of plants of the class and order hexandria polygynia. The essential character is, calyx three leaved; petals three; seeds several.

There are nine species, most of which may be found in England. They are inhabitants of watry places, bogs, &c.

ALKAHEST, or ALCAHEST, among the old chymists, denotes an universal menstruum capable of resolving all bodies into their first matter, or *ens primum*; and that without suffering any change or diminution by so doing.

Van Helmont assures us in the most positive manner, that he himself was master of such a menstruum. But, in this enlightened period, when chymical research has been extended further than it ever was before, the notion is deservedly ridiculed.

ALKALESCENT denotes a substance slightly alkaline, or in which alkali is beginning to be formed, and to predominate. See the next article.

ALKALI. This word is of Arabian origin, and was introduced into chymistry after it had been applied to the plant which still retains the name of *kali*. When this plant is burnt, the ashes washed in water, and the water evaporated to dryness, a white substance remains, which is called alkali. This, however, may be obtained from other substances besides the kali: and the word alkali is now applied to all bodies which possess, 1, a caustic taste; 2, the properties of being volatilized by heat; 3, of being capable of combining with acids; 4, of being soluble in water, even when combined with carbonic acid; and, 5, capable of converting vegetable blues to green.

The alkalies at present known are three in number: 1, potash; 2, soda; 3, ammonia. The two first are called fixed alkalies; they require a red heat to volatilize them. the last is called volatile alkali, because it readily assumes a gaseous form, and consequently is dissipated with a moderate degree of heat.

Alkalies readily unite with sulphur, forming compounds which have the property of absorbing the oxygen from the atmosphere, and when moistened, of giving out a peculiar and very fetid gas. These compounds were formerly called alkaline hepars or livers; but according to the modern nomenclature, they are denominated sulphurets. The alkalies have a very powerful action on almost all vegetable and animal matters, producing speedy disorganization, and reducing them to a pulp. With oils they form a compound known by the name of soap. They unite with all the acids, and produce neutral salts of various degrees of solubility; in which, when the contents are mutually saturated, the distinguishing properties of both acid and alkali are neutralized, and no longer to be perceived. From their affinity to acids, alkalies decompose the acid solutions of all metals and most earths. See CHYMISTRY.

ALKALINE *earths*, are those earths which agree with alkali in the property of solubility in water to a certain extent; of changing blue and red vegetable colours to green; of absorbing carbonic acid; and of possessing those acrid qualities that distinguish the alkalies. Magnesia, lime, barytes, and strontian, are deemed alkaline earths; but the former is very imperfectly so, being scarcely more soluble in water than silex. Barytes and strontian approach nearer to an alkali than lime, in being largely soluble in water.

ALKALINE *salts*. See MATERIA MEDICA.

ALKEKENGI, *winter cherry*. See PHYSALIS.

ALKERMES, in pharmacy, a compound cordial confection, made of various ingredients, as rose water, sugar, cinnamon, aloes wood, &c. but the principal one is kermes. It is now disused.

ALKORAN, or ALCORAN, [from the Arabic particle *al*, and *coran*, or *koran*, derived from the verb *craoa* or *karoa*, to read; signifying *the reading*, or rather *that which ought to be read*,] the scripture or bible of the Mahometans; containing the revelations and doctrines of their pretended prophet.

The alkoran is divided into 114 larger portions of very unequal length, which we call chapters, but the Arabians *sowar*, in the singular *sura*; a word rarely used on any

other occasion, and properly signifying a row, or a regular series. These chapters are not, in the manuscript copies, distinguished by their numerical order, but by particular titles, which are taken sometimes from a peculiar subject treated of, or person mentioned in them, usually from the first word of note. Some chapters have two or more titles, occasioned by the difference of the copies. Some of them being pretended to have been revealed at Mecca, and others at Medina, the noting this difference makes a part of the title. Every chapter is divided into smaller portions, of very unequal length also, which we customarily call verses; but the Arabic word is *ayat*, signifying signs or wonders. Besides these unequal divisions, the Mahometans have also divided their koran into 60 equal portions, each subdivided into four equal parts. But the koran is more usually divided into 30 sections only, each of twice the length of the former, and in like manner subdivided into four parts. These divisions are for the use of the readers of the koran in the royal temples, or in the adjoining chapels, where the emperors and great men are interred.

There are 29 chapters of the koran which have this peculiarity, that they begin with certain letters of the alphabet, some with a single one, others with more. These letters the Mahometans believe to be the peculiar mark of the koran, and to conceal several profound mysteries; the certain understanding of which the more intelligent confess has not been communicated to any mortal, their prophet only excepted.

The koran is universally allowed to be written with the utmost elegance and purity of language, in the dialect of the tribe of Koreish, the most noble and polite of all the Arabians, but with some mixture, though very rarely, of other dialects; and it is confessedly the standard of the Arabic tongue.

The great doctrine of the koran is the unity of God; to restore which, Mahomet pretended was the chief object of his mission: that there never was, nor ever can be, more than one true orthodox religion; that, though the particular laws or ceremonies are only temporary, and subject to alteration, according to the divine direction, yet the substance of it being eternal truth, is not liable to change, but continues immutably the same; and that, whenever this religion became neglected or corrupted in essentials, God had the goodness to re-inform and re-admonish mankind thereof by several prophets, of whom Moses and Jesus were the most distinguished, till the appearance of Mahomet, who is their seal, and no other to be expected after him.

The most excellent moral in the whole alcoran is that in the chapter *al alraf, viz.* "Show mercy, do good to all, and dispute not with the ignorant;" or, as Mr. Sale renders it, Use indulgence, command that which is just, and withdraw far from the ignorant. Mahomet, according to the authors of the *Keschaf*, having begged of the angel Gabriel a more ample explication of this passage, received it in the following terms: "Seek him who turns thee out, give to him who takes from thee, pardon him who injures thee; for God will have you plant in your souls the roots of his chief perfection." It is easy to see that this commentary is borrowed from the Gospel.

The caliph Hassan, son of Ali, being at table, a slave let fall a dish of meat reeking hot, which scalded him severely. The slave fell on his knees, rehearsing these words of the alcoran: "Paradise is for those who restrain their anger." "I am not angry with thee," answered the caliph. "And for those who forgive offences against them," continues the slave. "I forgive thee thine," replies the caliph. "But above all, for those who return good for evil," adds the slave. "I set thee at liberty," rejoined the caliph; "and I give thee ten dinars."

It is the common opinion that Mahomet, assisted by one Sergius, a monk, composed this book; but the Mussulmen believe it as an article of their faith, that the prophet, who they say was an illiterate man, had no concern in inditing it; but that it was given him by God, who, to that end, made use of the ministry of the angel Gabriel; that, however, it was communicated to him by little and little, a verse at a time, and in different places, during the course of 23 years. "And hence, say they, proceed that disorder and confusion visible in the work;" which, in truth, are so great, that all their doctors have never been able to adjust them. The alkoran, while Mahomet lived, was only kept in loose sheets: his successor, Abubeker, first collected them into a volume, and committed the keeping of it to Haphsa, the widow of Mahomet, in order to be consulted as an original; and there being much diversity between the several copies already dispersed throughout the provinces, Othman successor of Abubeker procured a great number of copies to be taken from that of Haphsa; at the same time suppressing all the others not conformable to the original.

ALKUSSA, a name given by the Swedes to a fish which they also call a *lake*. It is a species of the Silurus.

ALL *in the wind*, a phrase which expresses the state of the ship's sails when they are parallel to the direction of the wind.

ALL *hands hoay!* the phrase by which a ship's company are summoned upon deck.

ALLAMANDA, a genus of the pentandria monogynia class and order. The corolla is monopetalous and funnel shaped; and the essential character is, cor. contorted; caps. lens shaped, erect, echinate, one celled, two valved, many seeded. There is only one species, the A. cathartica. It grows wild in Guiana. The leaves are cathartic, whence the specific name; and are used at Surinam in the colic.

ALLANTOIS, or ALLANTOIDES, in comparative anatomy, a vesicle investing the fœtus of several animals, as cows, sheep, goats, &c. and filled with an urinous liquor conveyed thither from the urachus. See COMPARATIVE ANATOMY.

ALLAY, the same with alloy.

ALLEGATA, in Roman antiquity, a kind of subscription used by the emperors, importing the writings to be verified.

ALLEGATION, in law, signifies the producing instruments or deeds, to authorize or justify something.

ALLEGEAS, a stuff manufactured in the East Indies. There are two sorts; one of cotton, and the other of herbs, which is spun like flax or hemp.

ALLEGIANCE, in law, denotes the obedience which every subject owes to his lawful sovereign.

ALLEGIANCE, oath of, in the British policy, is that taken in acknowledgment of the king, as a temporal prince; as the oath of supremacy acknowledges him for the supreme head of the church.

This oath may be tendered to all persons above the age of twelve years, whether natives, denizens, or aliens,

either in the court leet of the manor, or in the sheriff's court. It is a necessary preliminary to the holding of any office of trust under the crown.

ALLEGORY, in literature, a figure of rhetoric; also a mode of writing, wherein something else is signified, than the words in their literal meaning express. An allegory may be considered as a series or chain of metaphors, continued through a great part of a discourse. For example, when the prophets represent the Hebrews under the allegory of a vine planted, cultivated, and watered by the hand of God, which, instead of producing good fruit, brings forth verjuice and sour grapes.

Allegories have entered into most religions: the Hebrew abounds with them, and it is well known that some philosophers of the Gentile world, undertaking to give a rational account of the many horrid absurdities which the poets had introduced into their religion, found it necessary to maintain that these fictions contained mysteries, and signified something very different from what they seemed to express. Hence came the word allegory, or a discourse that in its natural sense, αλλο αγοθευει, signifies some other thing than what seems intended to be meant. See RHETORIC.

ALLEGRO, in music, an Italian word denoting that the part is to be played in a sprightly, brisk, lively, and gay manner.

ALLELENGYON, in antiquity, a tax paid by the rich for the poor, when absent in the army.

ALLEMAND, a sort of grave solemn music, with good measure and a slow movement. It is also a kind of dance very common in Germany and Switzerland.

ALLERION, or ALERION, in heraldry, a sort of eagle without beak or feet, having nothing perfect but thewings.

They differ from martlets in this, that their wings are expanded, whereas those of the martlet are close; and denote imperialists vanquished and disarmed, for which reason they are more common in French than in German coats of arms.

ALLEVEURE, the smallest copper coin that is struck in Sweden. It is about $2\frac{1}{4}$d. of English money.

ALLEY, in perspective, that which, in order to have a greater appearance of length, is made wider at the entrance than at the termination.

ALLIANCE, in the civil and canon law, the relation contracted between two persons or two families by marriage.

An alliance is thus contracted between the husband and his wife's relations, between the wife and her husband's relations, but not between the relations of the husband and wife.

ALLIANCE is also used for a treaty entered into by sovereign princes and states, for their mutual safety and defence.

In this sense, alliances may be distinguished into such as are offensive, whereby the contracting parties oblige themselves jointly to attack some other power; and into defensive, whereby they bind themselves to support and defend each other, in case they are attacked by others. Under this head too may be ranked treaties of subsidy, which are well known to the English nation.

ALLIGATI, in antiquity, the basest and worst kind of slaves. The Romans had three kinds, or orders of slaves; the first employed in the management of their estates; the second in the menial or lower functions of the family; the third called *alligati*, these were kept in chains and dungeons.

ALLIGATION, in arithmetic, is the rule of mixture, which teaches to compound several species of ingredients or commodities together, according to any intent or design proposed, and is either medial or alternate. See ARITHMETIC.

ALLIGATOR, in zoology, the smaller kind of crocodiles. See LACERTA.

ALLIOTH, a star in the tail of the greater bear, much employed for finding the latitude at sea.

The word is also written *alliot* or *aliot*, denoting a horse. The Arabs give this name to each of the three stars in the tail of the Great Bear, on account of their appearing like three horses, ranged for the drawing of the waggon, represented by four stars, called Charles's wain.

ALLITERATION, a figure or decoration of language, chiefly used in poetry, and consisting in the repetition of the same letter or letters at certain intervals, whence its name is derived; thus in Lucretius:

——— Adverso *f*labra *f*eruntur
*F*lumine.

And in Shakespeare,

*H*ad my sweet *H*arry *h*ad but *h*alf their numbers,
This day might I, *h*anging on *H*otspur's neck, *H*ave talked.

ALLIONIA, a genus of plants of the class and order tetandria monogynia. The corolla is one petalled and funnel shaped; and the essential character is, calyx common, oblong, simple, three flowered; proper obsolete, superior: corollures irregular: recept. naked. There are two species, both natives of South America.

ALLIUM, GARLIC, in botany, a genus of plants, of the hexandria monogynia class and order. The corolla is six petalled, and the essential character is, corolla six parted, spreading: spathe many flowered: umbel heaped: capsule superior.

This is a very extensive genus of plants, comprehending the A. porrum or leek, the A. cepa or onion, with all their varieties, among which the A. canadense, or Canada tree onion, which bears excellent eatable onions on the top of the stalk, is most remarkable, the eschalot or shallot, the common garlic, the rocambole, which resembles the tree onion in bearing the garlic at the top of the stem as well as at the root, the Moly's, and a considerable tribe of flowering ornamental garlics. There are in all 45 species. The A. ursinum or ransoms, is a most disagreeable weed, on which if cows feed, their butter is not eatable. The A. descendens and triquetrum are very ornamental; the latter is treated as a green house plant. Garlic is used in many preparations in medicine and farriery.

ALLOCATIONE FACIENDA is a writ directed to the lord treasurer, or barons of the exchequer, commanding them to allow an accountant such sums as he has lawfully expended in the execution of his office.

ALLOCATO COMITATU, a new writ of exigent allowed, before any other county court held, on a former not being complied with.

ALLODIAL, an epithet given to an inheritance held without any acknowledgment to a lord or superior, in opposition to feudal.

Allodial lands are free lands, for which neither fees, rents, nor services, are due.

ALLODIUM *nobile*, that which had also civil and criminal jurisdiction annexed to it; in opposition to *allodium villanum*, which had no such jurisdiction.

ALLONGE, in fencing, denotes a thrust or pass at the adversary.

ALLOPHYLUS, a genus of the octandria monogynia class and order, and of the natural order of guttiferæ. The essential character is, calyx four leaved, leaflets orbiculate, two smaller; petal four less than the calyx; germ. twin; stigma quadrifid. There are 5 species; all trees but one, which is a shrub. They are natives of the East and West Indies.

ALLOTTING, or ALLOTMENT *of goods*, in commerce, is the dividing a ship's cargo into several parts, which are to be purchased by several persons, whose names being written upon as many slips of paper, are applied by an indifferent person to the several lots; by which means the goods are divided without partiality, each man having the parcel upon which his name is fixed.

ALLOTMENTS *of land*, are such portions of ground as are granted to claimants on the division and enclosure of commons and waste lands, and which are generally proportionate to the extent of the right which they enjoy upon them.

ALLOWANCES, at the custom house, to goods rated by weight, are two, *viz.* draught and tare.

ALLOY, or ALLAY, a proportion of a baser metal mixed with a finer one. Thus all gold coin has an alloy of silver and copper, as silver coin has of copper alone; the proportion in the former case, for standard gold, being two carats of alloy in a pound troy of gold; and in the latter, eighteen pennyweights of alloy for a pound troy of silver.

According as gold or silver has more or less alloy than that mentioned above, it is said to be coarser or finer than the standard. It ought, however, to be remarked, that the coin of different nations varies greatly in this respect; some using a larger, and others a less proportion of alloy, the original intention of which was to give the coin a due degree of hardness.

ALLUMÉE, in heraldry, a term applied to the eyes of a bear, or other beast, when they are drawn sparkling and red.

ALLUSION, in rhetoric, a figure by which something is applied to, or understood of another, on account of some similitude between them. An allusion to words is trifling and low, making what we commonly call a pun. Allusions, however, to some apophthegm, remarkable event, or generally received custom, are not only extremely pleasing, but approved by the best writers, ancient as well as modern.

ALLUVIAL *Limestone*, a sort of stone found in many districts, supposed to have been formed in the earliest ages of the world by the deposition of calcareous matters held in the state of solution in water.

ALLUVION, among civilians, denotes the gradual increase of land along the sea shore, or on the banks of rivers. This, when slow and imperceptible, is deemed a lawful means of acquisition; but when a considerable portion of land is torn away at once, by the violence of the current, and joined to a neighbouring estate, it may be claimed by the king. 2 Black. 262.

ALMADIE, a kind of canoe or small vessel, about four fathoms long, usually made of bark, and used by the negroes of Africa.

ALMADIE is also the name of a kind of long boats, fitted out at Calicut, which are eighty feet in length, and six or seven in breadth. They are exceedingly swift, and are otherwise called *cathuri*.

ALMAGRA, in natural history, the name of a fine deep red ochre, with a faint admixture of purple, used both in painting and medicine, being an excellent astringent. It is the same with what the ancients called *sil atticum*.

ALMANAC, a table containing the calendar of days and months, the rising and setting of the sun, the age of the moon, &c.

The first thing to be done in the construction of almanacs is to compute the sun's and moon's place for each day of the year, or it may be taken from some ephemerides and entered in the almanac; next find the dominical letter, and, by means thereof, distribute the calendar into weeks: then, having computed the time of Easter by it, fix the other moveable feasts; adding the immoveable ones, the rising and setting of each luminary, the length of day and night, the aspects of the planets, the phases of the moon, and the sun's entrance into the cardinal points of the ecliptic, *i.e.* the two equinoxes and solstices.

These are the principal contents of almanacs; besides which there are others of a political nature, and consequently different in different countries, as the birth days and coronation of princes, tables of interest, &c.

ALMANAC, *nautical* and *astronomical ephemeris*, is a kind of national almanac, published annually, by anticipation, under the direction of the commissioners of longitude. It contains among other things, the distances of the moon from the sun and fixed stars, for every three hours of apparent time, adapted to the meridian of Greenwich; by comparing which with the distances carefully observed at sea, the mariner may readily infer his longitude to a degree of exactness, that is found sufficient for most nautical purposes.

ALMARIC HERESY, one broached in France, in 1209, the distinguishing tenet of which was, that no Christian could be saved unless he believed himself to be a member of Christ.

ALME, singing and dancing girls in Egypt, who can occasionally chaunt unpremeditated verse. They derive their name from having received a better education than other women, and they form a celebrated society in the country. The qualifications for admission are, a good voice, a knowledge of the language and of the rules of poetry, and an ability to compose and sing couplets on the spot, adapted to the occasion.

ALMÉHRAB, in the Mahometan customs, a nich in the mosques, pointing toward the kebla, or temple of Mecca, to which they are obliged to bow in praying.

ALMEISAR, a celebrated game among the ancient Arabs, performed by a kind of casting lots with arrows, forbidden by Mahomet, on account of the frequent quarrels occasioned by it.

ALMENE, in commerce, a weight of two pounds, used to weigh saffron in several parts of the continent of the East Indies.

ALMENDINE, ALMANDINE, or ALBANDINE, a kind of ruby, but softer and lighter than the oriental ruby.

ALMERICANS, followers of the Almaric heresy, which see.

ALMOND TREE, see AMYGDALUS.

ALMOND, in commerce, a measure by which the Portuguese sell their oil; twenty-six almonds make a pipe.

ALMOND FURNACE, among refiners, that in which the slags of litharge, left in refining silver, are reduced to lead again, by the help of charcoal.

ALMOND is also a name given to a species of rock crystal, which lapidaries use in adorning branch candlesticks, &c. on account of the resemblance they bear to the fruit of the same name.

ALMONER, an officer appointed to distribute alms to the poor.

The lord almoner, or lord high almoner of England, is an ecclesiastical officer, usually a bishop, who has the forfeiture of all deodands, and the goods of all felos-de-se, which he is to distribute among the poor.

By virtue of an ancient custom, the lord almoner may give the first dish from the king's table to whatever poor person he pleases; or, in lieu of it, an alms in money.

The parishioners also of the parishes adjacent to the king's place of residence, nominate twenty-four poor men, to whom the lord almoner distributes four pence a day in money, bread and small beer.

ALMONER is sometimes also used for a deacon of a church, a chaplain, or even a legatee.

ALMONER is also used for a person who left alms to the poor, by his last will. It is sometimes used for a legatee; in this sense the same person cannot be both almoner and heir.

ALMS, a general term for what is given out of charity to the poor.

In the early ages of Christianity, the alms of the charitable were divided into four parts, one of which was allotted to the bishop, another to the priests, and another to the deacons and subdeacons, which made their whole subsistence; the fourth part was employed in relieving the poor, and in repairing the churches.

ALMS also denotes lands or other effects left to churches, or religious houses, on condition of praying for the soul of the donor. Hence,

ALMS *free*, was that which is liable to no rent or service.

ALMS *reasonable*, was a certain portion of the estates of intestate persons, allotted to the poor.

ALMUCANTARS, in astronomy, are the same with respect to the azimuths and horizon, that the parallels of latitude are with regard to the meridians and equator.

ALMUTAZAPHUS, a magistrate of Aragon, whose office it was to inspect measures and weights, and search houses for stolen goods.

ALNAGE, or AULNAGE, in the English polity, the measuring of woollen manufactures, with an aul or ell, and the other functions of the alnager.

Alnage was at first intended as a proof of the goodness of the commodity, and therefore a seal was invented as a signal, that the commodity was made according to the statute. But now that these seals may be bought and affixed to whatever commodity the buyer pleases, our rivals have acquired an opportunity of supplanting our trade with foreign nations, to the great prejudice of our woollen manufactures.

ALNAGER, see article above.

There were three officers relating to the alnage, namely, a searcher, measurer, and alnager: all which were anciently comprised in the alnager; the office is now abolished.

ALNUDE, a measure of liquids, the same with almond.

ALOA, in Grecian antiquity, a festival kept in honour of Ceres by the husbandmen, and supposed to resemble our harvest home.

ALOE, in botany, a genus of plants with a liliaceous flower, consisting of only one tubular petal, divided into six deep segments at the edge: its fruit is an oblong capsule, divided into three cells, and containing a number of angulated seeds. It is one of the hexandria monogynia class and order of Linnæus. See Plate Nat. Hist. fig. 12.

Several species of this exotic plant are cultivated in the gardens of the curious, where they afford a very pleasing variety, as well by the odd shape of their leaves as by the different spots with which they are variegated. The essential character is, corolla erect with an expanded mouth, and a nectareous base; filaments inserted into the receptacle.

Some aloes are arborescent, or divided into a number of branches, like trees; others are very small, growing close to the ground. There are in all 14 species, with a great number of varieties. It is from two varieties of one of the tree aloes, or A. arborescens, the medicine of that name is produced. The hepatic aloe is from a variety called the Barbadoes aloe, though it grows in most of the West India islands; the succotrine, from the aloe of that name, or sweet aloe. We are, however, of opinion, that an extract having the same properties might be prepared from most of the other species. The partridge breasted or variegata, and the mitriformis, are the most elegant in their foliage. But the humilis produces, in our opinion, the largest and handsomest flowers. It is a native of the Cape of Good Hope. Most of the species are best treated as green house plants; and like all other succulent plants, must be sparingly watered, especially in winter.

ALOE or ALOES, in pharmacy, the inspissated juice of the aloe, prepared in the following manner: from the leaves fresh cut, is drained or pressed a juice, the thinner and purer part of which is poured off, and set in the sun to evaporate to a hard yellowish substance or extract.

This extract is famous for its purgative virtues, being frequently given in the form of a tincture in wine, which is called *hiera picra;* in a solid form called pil. de rufi, &c. and in the popular quack medicine, called Anderson's Scotch Pills.

ALOE *rosata*, a preparation of succotrine aloes, which being dissolved in the juice of roses, or violets, and exposed to the sun, or put upon a slow fire, thickens to a consistency proper for making pills.

Aloes is accounted an excellent purging medicine, especially to cold constitutions, a good stomatic, and, applied outwardly, is serviceable in cicatrizing wounds.

ALOEDARY, among ancient physicians, a purging medicine, the chief ingredient of which was aloes. It is also used for a history of the class of plants, under the denomination of aloes.

ALOFT, a sea term, synonymous with "up in the tops," "at the mast head," or any where about the higher rigging.

ALOGIANS, in church history, a sect of ancient heretics, who denied that Jesus Christ was the Logos, or eter-

nal word; and consequently rejected the Gospel of St. John, as spurious.

ALOGOTROPHIA, among physicians, denotes an unequal nutrition, or growth, in some part of the body, as is the case in the rickets.

ALONG *side*, in sea language, expresses side by side, or joined to a ship, wharf, &c.

ALONG *shore*, a phrase expressing along the coast, or a course which is in sight of, and nearly parallel to the shore.

ALONG, *lying*, the state of a ship that is pressed down sidewise, by the weight of the sail.

ALOOF, in sea language, a word of command to the man at the helm, to keep the ship near the wind, when sailing upon a quarter wind.

ALOPECIA, in medicine, denotes a falling off of the hair, occasioned either by a defect of nourishment, or by a bad state of the humours.

Some make a distinction between the *alopecia* and *defluvium capillorum:* as in the former, certain spots are left entirely bald; whereas, in the latter, the hair only grows excessively thin. They likewise distinguish it from the *ophiasis*, as the baldness in this last creeps in spiral lines about the head, like the windings of a serpent. The intention of cure, however, seems to be much the same in them all, *viz.* to supply proper nourishment, where that is wanting; and to correct the bad qualities of the humours, where these are in fault.

ALOPECURUS, FOX TAIL GRASS, in botany, a distinct genus of plants, the flower of which consists of only one hollow valve, with a long awn or beard inserted on its back part, near the base: it is one of the triandria digynia of Linnæus. The essential character is, calyx two valved; corolla one valved.

There are seven species. The A. pratensis, or meadow fox tail, is esteemed by some farmers, but in our opinion its value has been overrated. The A. arvensis, or field fox tail, is a smaller plant of the same description, and flowers early; but it is even less valuable than the preceding, and we believe is never cultivated.

ALOUCHI, a sweet scented gum, which runs from the tree that produces white cinnamon.

ALPHABET, in matters of literature, the natural or accustomed series of the several letters of a language.

All the alphabets extant are charged by bishop Wilkins with great irregularities, with respect both to order, number, power, figure, &c.

As to the order, it appears, says he, inartificial, precarious, and confused, as the vowels and consonants are not reduced into classes, with such order of precedence and subsequence as their natures will bear. Of this imperfection the Greek alphabet, which is one of the least defective, is far from being free: for instance, the Greeks should have separated the consonants from the vowels; after the vowels they should have placed the diphthongs, and then the consonants; whereas, in fact, the order is so perverted that we find the ο the fifteenth letter, in order of the alphabet, and the ω, or long o, the twenty-fourth and last; the ε the fifth, and the η the seventh.

With respect to number they are both redundant and deficient; redundant, by allotting the same sound to several letters, as in the Latin c and *k*, *f* and *ph;* or by reckoning double letters among the simple elements of speech, as in the Greek ξ and ψ, the Latin *q* or *cu*, *x* or *cs*, and the *j* consonant; deficient in many respects, particularly with regard to vowels, of which seven or eight kinds are commonly used, though the Latin alphabet takes notice only of five. Add to this, that the difference among them, with regard to long and short, is not sufficiently provided against.

The powers again are not more exempt from confusion; the vowels, for instance, are generally acknowledged to have each of them several different sounds; and among the consonants we need only bring as evidence of their different pronunciation, the letter *c* in the word *circa*, and *g* in the word *negligence*. Hence it happens, that some words are differently written, though pronounced in the same manner, as *cessio* and *sessio;* and others are different in pronunciation which are the same in writing, as *give*, *dare*, and *give*, *vinculum*.

Finally, the figures are but ill concerted, there being nothing in the characters of the vowels answerable to the different degrees of apertion; nor in the consonants analogous to their agreements or disagreements.

Alphabets of different nations vary in the number of their constituent letters. The English alphabet contains twenty-four letters, to which if *j* and *v* consonants are added, the sum will be twenty-six; the French twenty-three; the Hebrew, Chaldee, Syriac, and Samaritan twenty-two each; the Arabic twenty-eight; the Persian thirty-one; the Turkish thirty-three; the Georgian thirty-six; the Coptic thirty-two; the Muscovite forty-three; the Greek twenty-four; the Latin twenty-two; the Sclavonic twenty-seven; the Dutch twenty-six; the Spanish twenty-seven; the Italian twenty; the Ethiopic, as well as Tartarian, two hundred and two; the Indian of Bengal twenty-one; the Baramos nineteen; the Chinese, properly speaking, have no alphabet, except we call their whole language their alphabet; their letters are words, or rather hieroglyphics, and amount to about 80,000.

If alphabets had been constructed by able persons, after a full examination of the subject, they would not have been filled with such contradictions between the manner of writing and reading, as we have shown above, nor with those imperfections that evidently appear in the alphabets of every nation. Mr. Lodowic, however, and bishop Wilkins, have endeavoured to obviate all these, in their universal alphabets or characters.

Dr. Franklin also spent much time in devising some mode of improving the alphabet, though his plan is, in many respects, exceptionable. But waving for a moment the difficulty, not to say impossibility, of effecting any change in the established alphabet, however useful that change may be; we have seen no attempt, which combines greater advantages in its object, or deserves so much attention, as the one lately made by Thomas Embree; he has given us 33 characters with the appropriate sound of each, so as to unite in every instance the orthography, with the most approved pronunciation; but our limits will preclude an explanation of his plan; we refer the curious to his treatise upon the subject, entitled "Orthography corrected." (*a*)

ALPHERATZ, a fixed star of the third magnitude, in Aquarius.

ALPHONSIN, in surgery, an instrument for extracting bullets out of gunshot wounds.

This instrument derives its name from the inventor, Alphonsus Ferrier, a physician of Naples. It consists of three branches, which are closed by a ring. When closed and introduced into the wound, the operator draws back the ring toward the handle, upon which the branches opening take hold of the ball; and then the ring is pushed from the haft, by which means the branches grasp the ball so firmly as to extract the ball from the wound. See SURGERY.

ALPINIA, a genus of the monandria monogynia class and order. The corolla is monopetalous and tubulose; and the essential character is, calyx three toothed, equal, tubulose; corolla three parted, equal; nect. two lipped, the lower lip spreading.

There is but one species, called after Prosper Alpinus, a famous botanist. It is a native of the West Indies. It is with us treated as a stove aquatic.

ALQUIER, a liquid measure used in Portugal to measure oil, two of which make an almond.

ALQUIFORE is a sort of mineral lead, very heavy, easily reduced to powder, and difficult to fuse. The potters use it to give their works a green varnish. It is found in Cornwall, and called potter's ore. It contains probably some mixture of cobalt.

ABEAMECH, in astronomy, the name of a star of the first magnitude, otherwise called arcturus.

ALSINE, CHICKWEED, the name of a genus of plants, of the class and order of pentandria trigynia. The corolla is five equal petals, which, with the five leaved calyx and a capsule one celled, three valved, form the essential character. Happily for gardeners there are but three species of this vile weed, and but one in England. This however, though an annual, affords sufficient trouble. It appears to be of no use whatever, though it is called chickweed, from the notion that chickens feed on it, which must be when they can get nothing else.

ALSIRAT, in the Mahometan theology, denotes a bridge laid over the middle of hell, the passage or path whereof is sharper than the edge of a sword; over which, however, every soul must pass at the day of judgment, when the wicked will tumble headlong into hell, whereas, the good will fly over it.

ALSTONIA, a genus of the polyandria monogynia class and order. The corolla is shorter than the calyx; and the essential character is, corolla one petalled, eight or ten cleft; the clefts alternated. There is only one species, a shrub of South America, the leaves of which are said to have the taste of tea.

ALSTROEMERIA, a genus of plants of the hexandria monogynia class and order, and of the natural order of lilia. The essential character is, corolla six petals, subbilabiate; the two lower petals tubulose at the base; stamina bending down.

There are six species, all natives of South America. They are cultivated here as ornamental plants. The A. pelegrina and ligtu are the most beautiful and the most common. The former will bear to be treated as a green house plant, and some assert that it thrives best even in a garden frame.

ALTAR THANE, in our old law books, an appellation given to the priest, or parson of a parish, to whom the altarage belonged.

ALTARAGE, among ecclesiastical writers, denotes the profits arising to a priest on account of the altar, as well as the offerings themselves made upon it.

ALTERANTS, or ALTERNATIVE *medicines*, in pharmacy, such medicines as are supposed to correct the bad qualities of the blood and other animal fluids, without occasioning any sensible evacuation.

ALTERN BASE, in trigonometry, a term used in contradistinction to the true base. Thus, in oblique triangles, the true base is either the sum of the sides, and then the difference of the sides is called the altern base; or the true base is the difference of the sides, and then the sum of the sides is called the altern base.

ALTERNATE, in heraldry, is said in respect of the situation of the quarters.

Thus the first and fourth quarters, and the second and third, are usually of the same nature, and are called alternate quarters.

ALTERNATE, such a disposition of the leaves of a plant, that the first on one side of a branch stands higher than the first on the other side, the second the same, and so on to the top.

ALTERNATE *allegation*. See ARITHMETIC.

ALTERNATE *angles*. See GEOMETRY.

ALTHÆA, MARSH MALLOW, a genus of plants, with a double calyx, the exterior one being divided into nine segments; the fruit consists of numerous capsules, each containing a single seed. It belongs to the monadelphia polyandria class of Linnæus. The essential character is, calyx double, outer nine cleft; arils many, one seeded.

There are seven species, of which the A. officinalis, or common marsh mallow, is well known. It was formerly supposed to possess many medical virtues, but is now scarcely used in any preparation whatever. The flowers and seed are nearly the same with those of the malva, or mallow.

ALTIN, in commerce, a kind of money current in Muscovy, worth three copics.

ALTITUDE, in geometry, one of the three dimensions of body; being the same with what is otherwise called height.

ALTITUDE *of a figure*, is the nearest distance of its vertex from its base, or the length of a perpendicular let fall from the vertex to the base.

ALTITUDE, in optics, is the height of an object above a line, drawn parallel to the horizon from the eye of the observer, or the angle subtended between a line drawn through the eye parallel to the horizon, and a visual ray emitted from an object to the eye. See OPTICS.

ALTITUDE *of the eye*, in perspective, is its perpendicular height above the geometrical plane.

ALTITUDE *of a star*, &c. in astronomy, is an arch of a vertical circle, intercepted between the star and the horizon.

This altitude is either true or apparent, according as it is reckoned from the rational or sensible horizon; and the difference between these is what is called by astronomers the parallax of altitude.

The true altitudes of the sun and fixed stars differ but little from their apparent altitudes, because of their great distance from the earth, and the smallness of the earth's semidiameter compared with it. The quantity of refraction is different at different altitudes, and the parallax is

different, according to the distance of celestial objects; in the fixed stars it is too small to be observed with any degree of certainty: that of the sun is about $8\frac{2}{3}$ sec. and that of the moon 52 min.

Sailors commonly take the altitude of stars with a quadrant, but as this method is liable to an error of six, seven, or more minutes, from the motion of the ship, as well as the coarseness of their instruments, Mr. Parent has given a new way of finding their altitudes, by means of a common watch. His method is this; having observed the difference of time between the rising of two stars, the right ascension and declination of which are known from astronomical tables, in the Nautical Almanac, it will be easy to distinguish that part of the difference which arises from that different position, from that arising from the obliquity of the sphere. Now this last is precisely the altitude of the pole of the place of observation; for as to the way the ship may have made between the rising of the two stars, it is so small as to be safely overlooked, or at most estimated in the common way of reckoning.

The ship changing place between the two observations, renders this method liable to some objection; but the small alteration either of the ship's longitude or latitude will make no sensible error, and if she happens to have run a good distance between the observations, it is easy reckoning how much it is, and accordingly allowing for it. See Navigation.

Altitude, *accessible*, &c. See Trigonometry. See also Gnomon, Pin, Quadrant, &c.

Altitude, *refraction of*, is an arc of a vertical circle, by which the altitude of a heavenly body is increased by means of refraction. This is different at different altitudes, being nothing at the zenith, and greatest at the horizon.

Altitude, *parallax of*, the difference between the true and apparent place of a star: it diminishes the altitude of the star, or increases its distance from the zenith.

Altitude *of motion*, according to Dr. Wallis, is its measure estimated in the line of direction of the moving force.

Altitude, *determinative*, that whence a heavy body falling, acquires a certain velocity by its natural acceleration.

ALTO RELIEVO. See Relievo.

ALTO RIPIENO, in music, the tenor of the great chorus which sings or plays only now and then in some particular places.

ALVARID, in the history of Spain, a kind of magistrate or judge, differing very little from the alcaid.

ALVARISTS, a branch of thomists, so called from Alvares their leader, who asserted sufficient grace, instead of the efficacious grace of the ancient thomists.

ALUDE, a kind of sheep's leather, one side of which has the wool on.

ALUDELS, in chymistry, are earthen pots ranged one above another, for retaining the products which ascend in the process of sublimation.

The lowest aludel is fitted to a pot, placed in the furnace, in which is the matter to be sublimed; and at top is a close head to retain the sublimates which ascend highest.

ALVEARIUM, among anatomists, denotes the hollow of the auricle, or outer ear.

ALVEHEZIT, denotes, among Arabian writers, what we call falling stars.

ALVEOLATE, in botany, a term used in the same sense as *honey combed*, to express something that is furrowed by oblong depressions.

ALVEOLUS, in anatomy, the socket like cavity in the jaws, wherein each of the teeth is fixed.

Alveolus, in the history of fossils, a marine body, not known at present in its recent state, but frequently found fossile.

The alveoli are of a conic shape, and composed of a number of cells, like so many bee hives, jointed into one another, with a pipe of communication, like that of the nautilus. They are sometimes met with entire, but more frequently truncated, or with their smaller ends broken off.

ALULA notha, bastard or spurious wing, in ornithology, is a kind of appendage to the true and principal wing, placed near its outer extremity, at the base of the primary quill feathers, and consists of from three to five small feathers of the quill kind.

ALUM, a neutral salt, the base of which is alumina, argil, or clay, combined with sulphuric acid.

Alum, *ores of*, include all those minerals which either contain alum ready formed, or are capable of yielding this salt by manufacture: they may be divided, 1, into the *saline*, all the species of which are almost wholly soluble in water; 2, the *earthy saline*, the soluble particles of which are diffused through a large proportion of earth; 3, the earthy, which containing no alum, but the materials of it, are insoluble, and destitute of that sweetish astringent taste which characterizes the two former.

There are four varieties of alum, which are all triple salts; two neutral, and two in the state of super salts. These varieties Dr. Thomson distinguishes by the following names:

1. Sulphate of alumina and potash.
2. Sulphate of alumina and ammonia.
3. Supersulphate of alumina and potash.
4. Supersulphate of alumina and ammonia.

The two last of these varieties are usually confounded under the name of alum; the two first have been called *alum saturated with earths*, or *aluminated alum*.

We owe the discovery of alum to the Asiatics, and it continued to be imported from the East till the fifteenth century, when a number of alum works were established in Italy. In the sixteenth century it was manufactured in other parts of the continent; and during the reign of queen Elizabeth an alum work was established in England.

The composition of alum has been but lately understood with accuracy. It has, indeed, been long known that sulphuric acid is one of the ingredients, and it was equally certain that alumina is another. But these are incapable of forming alum. The addition of potash, or of ammonia, or of some substance containing these alkalies, is almost always necessary; and where these additions are not wanted, the earth from which the alum is obtained contains already a quantity of potash. Hence it appears that alum is properly a triple salt, composed of sulphuric acid, alumina, and potash or ammonia united.

Alum crystallizes in regular octahedrons, consisting of two four sided pyramids applied base to base, the sides are equilateral triangles. Its taste is sweetish and very astringent. It always reddens vegetable blues: its specific gravity is 2.711 nearly. At the temperature of 60

degrees, it is soluble in from 15 to 20 parts of water, and three fourths of its weight in boiling water. When exposed to the air it effloresces slightly. When exposed to a gentle heat it undergoes the watry fusion. A very strong heat causes it to swell and foam, and to lose 44 per cent. of its weight, consisting chiefly of water of crystallization; what remains is called calcined or burnt alum, and is sometimes used as a corrosive. By a still more violent heat, the greater part of the acid may be driven off.

There are three varieties of alum in commerce, 1, the *supersulphate of alumina and potash;* 2, *supersulphate of alumina and ammonia;* and, 3, a mixture of these two, which contains both potash and ammonia. This is the most common, because the manufacturers of alum use both urine and muriate of potash to crystallize their alum. The first variety is composed of

49 Sulphate of alumina
7 Sulphate of potash
44 water

100.

Crystallized alum contains,
17.66 acid
12.00 base
70.34 water

100.

Burnt alum contains,
36.25 acid
63.75 base

100.

When an unusual quantity of potash is added to alum liquor, the salt loses its usual form, and crystallizes in cubes; this is called *cubic* alum, and contains an excess of alkali; and when the potash is still further increased, the salt loses the property of crystallizing, and falls down in flakes: it then consists of sulphate of potash combined with a small proportion of alumina.

All the varieties of alum are capable of combining with an additional dose of alumina, and forming perfectly neutral compounds.

Alum is of great importance as a mordant in dying; it is used also in the manufacture of leather, it is employed by calico printers, engravers, &c. and it is used in medicine, in preserving animal substances from putrefaction, and in preventing wood from taking fire.

If three parts of alum, and one of flour or sugar be melted together in an iron ladle, and the mixture dried till it becomes blackish and ceases to swell; if it be then pounded small, put into a glass phial, and placed in a sand bath till a blue flame issues from the mouth of the phial, and after burning a minute or two be allowed to cool, a substance is obtained call Homberg's phosphorus, which has the property of catching fire when exposed to the open air, especially if it be moist. See Thomson's Chymistry, vol. ii.

ALUM, *native*, or *fossile* ALUM, that formed by nature, without the assistance of art.

There are still mines of native alum in the island of Chio, consisting of a kind of vaults, or apartments crusted over with alum, which may be regarded as exfoliations from the rocks.

ALUM, *plumose*, or *plume* ALUM, a kind of natural alum, composed of a sort of threads, or fibres, resembling feathers; whence it has its name.

ALUM, *prepared*, or *purified* ALUM, that which is dissolved in hot rain water, and afterward made to crystallize, by evaporating the water.

ALUM, *Roman*, a sort of rock alum, of a reddish colour, made in the country near Rome.

ALUM, *saccharine*, is a composition of common alum with rose water, and clarified by the whites of eggs, which being boiled to the consistence of a paste, is formed in the shape of a sugar loaf; hence it obtained its name: it is used as a cosmetic.

ALUMINA derives its name from alum, of which it is the base. It is the argilaceous part of common clay, or, in other words, pure argil or clay, free from all impurities. It is smooth and unctuous to the touch, when pure, diffusible in water, and adhering to the tongue. Its specific gravity is 200. Its bulk is diminished by great heat, and its hardness may be so increased by baking as to enable it to strike fire with steel. It forms a difficult combination with the acids. With the sulphuric it makes sulphate of alumina; but its crystallization is difficult, both with the nitre and muriatic. It has a powerful attraction for lime. The most intense heat is not able to melt it alone, but it is easily fusible when lime or an alkali is added to it. By its mixture with water and silex it acquires great solidity.

ALUMINOUS WATERS, those impregnated either naturally or artificially, with the virtues of alum.

Of the former kind is the spa at Scarborough represented to be; and of the latter, the *aqua aluminosa* of the shops.

ALUNGU is a name given by the people of Malabar to an animal resembling a large lizard, except as to head and tail, which are both pointed. It is of the species of the manis of Linnæus, and belongs to the family of ant eaters; which have no teeth, but a round tongue, with which they catch ants.

ALURNUS, a genus of insects of the order of coleoptera, with filiform antennæ, six short feelers, and a horny arched jaw. Three species of them are found at the Cape of Good Hope, *viz.* A. grossus, femoratus, and dentipes. See Plate Nat. Hist. fig. 13.

ALWAIDID, a sect of Mahometans, who believe all great crimes to be unpardonable.

ALYSSUM, or ALYSSON, *madwort*, in botany, a genus of the tetradynamia siliculosa class and order, of the natural order of siliquosæ and cruciferæ of Jussieu. The flower is of the cruciform kind, and consists of four petals; the fruit is a small roundish capsule, divided into two cells, in which are contained a number of small roundish seeds. The essential character is, the shorter filaments marked with a toothlet; the silicle emarginate.

There are 17 species. The A. palimifolium, or sweet alyssum, is an annual plant, chiefly cultivated in gardens for its fragrance. The yellow alysson is also very ornamental, and is perennial.

AMA, among ecclesiastical writers, denotes a vessel in which wine or water was kept for the service of the eucharist.

AMA is sometimes also used for a wine measure, as a pipe, &c.

AMABYR, or AMVABYR, a barbarous custom which formerly prevailed in Wales, and some other parts of the kingdom; being a certain fine, or sum of money, paid to the lord, upon marrying a maid within his manor.

AMADOW, a kind of black match, tinder, or touch-wood, which comes from Germany. It is made from spongy excrescences, which often grow on old trees, especially oaks, ash, or firs. This substance being boiled in common water, and afterward dried and well beaten, is then put into a strong ley prepared with saltpetre, after which it is again put to dry in an oven, when it is fit for use.

AMADOWRY, a kind of cotton, which comes from Alexandria, by way of Marseilles.

AMAIN, or AMAYNE, in sea language, a term importing to lower something at once. Thus, to strike amain, is to lower, or let fall the topsails.

AMALGAM, a mass of mercury united and incorporated with some other metal.

Amalgams grow soft with heat and hard with cold; and the metals amalgamated with mercury, assume a consistence harder or softer, in proportion to the quantity of mercury employed in the amalgam.

Amalgams are used either to render a metal fit to be extended on some works, as in gilding; or else to reduce the metal into a very subtile powder.

Thus gilders, to lay gold on any other metal, dissolve it in hot mercury; which done, they apply the solution on the body to be gilt, then setting it over the coals, the mercury evaporates, and leaves the gold adhering to the body like a crust.

The amalgams of gold, silver, tin, lead, zinc, bismuth, and copper, are all white; and when the proportion of the quantity of the other metal to that of mercury is considerable, they form a kind of paste.

AMALGAMATION, in chymistry, the operation of making an amalgam, or of mixing quicksilver with some metal, is performed by fusing, or at least igniting the metal, and in this state adding a proportion of mercury to it; upon which they mutually attract and incorporate with each other.

Of all metals, gold unites with mercury with the greatest facility; next to that, silver; then lead, tin, and every metal, except iron and copper, the last of which incorporates with quicksilver with great difficulty, and the former scarcely at all.

The amalgam of gold is thus made: take a dram of gold, beat it into very thin plates, and upon these, heated in a crucible red hot, pour an ounce of quicksilver; stir the matter with an iron rod, and when it begins to fume, cast it into an earthen pan filled with water, and it will coagulate and become tractable. Gold will retain about thrice its weight of mercury.

To make an amalgam of lead; melt clean lead in an iron ladle, add to it an equal weight of melted mercury, stir them together with an iron rod, then let them cool, and you will have an uniform mass of a silver colour, somewhat hard, but growing softer and softer by trituration. Put this mass into a glass mortar, grind it, and mix with it any quantity of mercury at pleasure, and it will unite with it, as salt with water.

The amalgam of tin is made exactly in the same manner, and this also may be diluted by the addition of mercury.

To have an amalgam of copper, take a solution of pure copper, made in aquafortis, so strong that the aquafortis could dissolve no more of the metal; dilute the solution with twelve times its quantity of water; heat the liquor, and put into it polished plates of iron, and the copper will be precipitated in a powder to the bottom, while the iron will be dissolved: proceed thus till all the copper is fallen, pour off the liquor, wash the powder with hot water, till it becomes perfectly insipid; then dry the powder, and grind it in a glass mortar with an equal weight of hot quicksilver, and they will unite into an amalgam, which will also receive a further addition of mercury. An amalgam of copper in any other way is very difficult to make.

Pure silver precipitated from aquafortis, may in the same manner be made into an amalgam.

From these operations we may perceive that the making of amalgams is the foundation of the art of gilding, both in gold and silver, and that metals by that art may be mixed, confounded, and secretly concealed among one another.

Amalgams are also used in electricity; the rubber being always prepared by laying on it a small quantity of amalgam, which is in general made of zinc, triturated with tallow. See ELECTRICITY. An amalgam of tin and mercury is used for looking-glasses. In this case, the glass plate is laid on an even board, on which is spread very evenly some tin foil, and on the tin foil is spread quicksilver: the glass is then laid on the quicksilver, and a number of leaden weights, covered with baize or flannel, are laid upon the glass; in this state it remains several days, till the tin and quicksilver, in the state of amalgam, adhere firmly to the glass, by means of which it acquires the power of reflection.

AMAN, a sort of blue cotton cloth, which comes from the Levant by the way of Aleppo.

AMARANTA, or AMARANTE, an order of knighthood, instituted in 1653, by Christina, queen of Sweden, in memory of a masquerade, in which she had assumed that name, which signifies unfading, or immortal.

AMARANTHUS, in botany, the name of a genus of plants, sometimes called prince's feather, the flower of which is rosaceous, and its fruit an oval or roundish capsule, containing only one large seed of a roundish compressed shape. The characters are: the male calyx is a five or three leaved perianthium, erect, coloured, and persistent: there is no corolla: the stamina consist of five or three erect capillary filaments, the length of the calyx; the antheræ are oblong and versatile: the female calyx the same as the male, and no corolla: the pistillum has an ovate germen; the styli are three, short and subulated; the stigmata simple and persistent: the pericarpium is an ovate capsule, three beaked, unilocular, and cut round: the seed is one, globular, compressed, and large. Of this there are 29 species; the most remarkable of which are:

Amaranthus bicolor, melancholicus, or two coloured amaranthus. This greatly resembles the tricolor in its manner of growth; but the leaves have only two colours, which are an obscure purple, and a bright crimson. These are so splendid, as to set off each other, and when the plants are vigorous, make a fine appearance. Amaranthus maximus, or tree like amaranthus, grows with a strong stem to the height of seven or eight feet. Amaranthus

oleraceus, with obtuse indented leaves. This has no beauty; but it is used by the Indians as a substitute for cabbage. Amaranthus tricolor, or three coloured amaranthus. This has been long cultivated in gardens on account of the beauty of its variegated leaves, which are green, yellow, and red, very elegantly mixed. The amaranths are all annual.

AMARYLLIS, a genus of the hexandria monogynia class and order, of the natural order of lilia, which in its flower it resembles. The essential character is, corolla hexapetaloid, irregular; filaments inserted into the throat of the tube, bending down, unequal in proportion or direction. There are 29 species, all of them highly ornamental, but only one, the A. lutea, perfectly hardy in this country. The A. regina, the vittata, the jacobea, belladonna, and Guernsey lily, are well known in the stoves and green houses of the curious in plants. To describe them is impossible, but no flowers are more beautiful.

AMASONIA, a genus of the didynamia angiospermia class and order. The corolla is one petalled: and the essential character is corolla tubulous; limb small, quinquefid: the seed is a nut, ovate and one celled. We know of but one species, the erecta, a native of Surinam. The stem is herbaceous, and grows to the height of three feet.

AMAUROSIS, among physicians, a distemper of the eye, otherwise called *gutta serena*.

AMAUSA, a name given by chymists to the pastes used in counterfeiting gems.

AMAZONS, an ancient nation of women, inhabiting that part of Lesser Asia, now called Amasia.

The Amazons are said to have killed all their male children, and to have cut off the right breasts of their females, to fit them for martial exercises. The existence, however, of such a nation is controverted by the most judicious authors, particularly Mr. Bryant, and defended by others, particularly Mr. Petit, a French physician, who has published a dissertation on the subject, wherein are several curious inquiries concerning their arms, dress, &c.

We also read of Scythian Amazons, of German Amazons, of Lybian Amazons, and Amazons of America, living on the banks of the great river which bears their name, who are represented as governed by a queen, no men being permitted to live among them; only, at a certain season, those of the neighbouring nations are suffered to visit them. The Amazons of Lybia are famous for their wars with another female nation, called Gorgons. The whole of these stories appear to us little better than fabulous.

AMAZONE, a very fine antique statue, in Parian marble, in the gallery of antiques at Paris. There is also a beautiful statue of the queen of the Amazons at Wilton, represented in a warlike attitude, which was executed by Cleomenes.

AMBE, among surgeons, an instrument for reducing dislocated bones, consisting of a horizontal lever, moved by a hinge, upon a vertical standard or foot.

Ambe, among anatomists, a term used for the superficial jutting out of a bone.

AMBER is a bituminous concrete, of a yellow or brown colour, and more or less transparent. In its colour, however, there is considerable variety; some pieces being clear and transparent, some opaque and whitish, some dark coloured; the most valued specimens are of a pale yellow colour. On being slightly rubbed, it acquires electric powers. Only a small portion of it is dissolved by spirit of wine. It affords the most remarkable phenomena when exposed to heat. Being rubbed, the odour of it that exhales resembles the aromatic resinous substances, and is increased. In a greater heat it acquires a brown colour, emits some steams, and undergoes a state of fusion. It then becomes quite dark and opaque, and is employed in this state in the composition of some varnishes. In burning it emits very penetrating vapours, burns with a grayish flame, and leaves a coaly residuum.

When this substance is distilled, the empyreumatic oil produced is mostly thick, and of a blackish colour, and has a heavy, penetrating odour. When it is repeatedly distilled it becomes more fluid and transparent, and can be rendered quite limpid; in which state it is said to resemble the finer kinds of petrolea, particularly the naphtha. It is then termed rectified oil of amber.

The origin of amber has been much disputed, whether it is originally a fossil, or is produced from vegetable matter. The only reason to imagine it is entirely a fossil body is, that it is found at some depth below the surface under certain strata. The greatest part that we have comes from the Baltic. A considerable quantity is found floating on the sea on these coasts, being washed out of the soil by the agitation of the waves, when they penetrate through different strata, first through one containing fossil wood, variously compacted together; under this a stratum of vitriolic minerals; below this the amber is found dispersed in various sizes; but when it is examined, we find manifest proofs of its having been produced originally at the surface of the earth; parts of vegetables, and even insects, being occasionally found in it.

Amber is used for trinkets, particularly in Turkey and the East; but the finest specimens are in the cabinet of the king of Prussia.

AMBERGRIS resembles amber in several chymical qualities. It is a light ash coloured body found on the sea shores in the East Indies. It is opaque, and of a granulated structure. It has a light agreeable odour; melts with a gentle heat, without suffering any change; and, if further heated in close vessels, it gives an oil like that of amber. It also dissolves in spirit of wine, by means of heat, and is used in composition of perfumes. It is not affected by acids.

The origin of this substance is uncertain. It appears to be somewhat similar to that of amber. It is found in masses, from one to a hundred ounces. The greatest quantity is found floating in the Indian ocean; but we also meet with it in our own and in the northern seas. It is found likewise adhering to the rocks, and in the stomachs of the most voracious fishes; these animals swallowing at particular times every thing they happen to meet with. It has been particularly found in the intestines of the eschalot whale, and most commonly in sickly fish, whence it is supposed either the cause or effect of disease. We often find in it relics of animal and vegetable substances, the bones and beaks of birds and insects; and as it resembles beeswax, melting like it, it would appear that it has been originally beeswax, which having been buried under the surface of the earth, or having floated a long time on the ocean, has undergone a considerable change; and we know the amazing quantity of beeswax and honey

that is sometimes collected by bees in their wild state, as in America. In old trees quantities have been found, sufficient for filling several hogsheads; and in rocks and caves along the sea shore, quantities may be gathered together; and by being buried, or by floating on the water, they may undergo a change, so as to be converted into this substance.

AMBIDEXTER, a person who can use both hands with the same facility, and for the same purposes, that the generality of people do their right hands.

Was it not for education, some think that all mankind would be ambidexters; and, in fact, we frequently find nurses obliged to be at a good deal of pains before they can bring children to forego the use of their left hands. It is perhaps a pity that any of the gifts of nature should be thus rendered in a great measure useless, as there are many occasions in life which require the equal use of both hands: such are the operations of bleeding in the left arm, left ancle, &c.

AMBIDEXTER, among lawyers, a juror or embracer, who accepts money of both parties for giving his verdict; an offence for which he is liable to be imprisoned, for ever excluded from a jury, and to pay ten times the sum he accepted of.

AMBIGENAL HYPERBOLA, a name given by sir Isaac Newton to one of the triple hyperbolas of the second order, having one of its infinite legs falling within an angle formed by the asymptotes, and the other falling without. See CONIC SECTION.

AMBIGUITY, in rhetoric and grammar, a defect of language, whereby words are rendered equivocal.

AMBIT, in geometry, is the same with what is otherwise called the perimeter of a figure.

AMBITUS, whence our word *ambition*, in Roman antiquity, the offering for some magistracy or office, and formally going round the city to solicit the interest and vote of the people.

On these occasions it was not only usual to solicit the interest of their friends and others, with whom they were personally acquainted; but the candidates, being attended by persons of an extensive acquaintance, who suggested to them the names of the citizens, and thence called *nomenclatores*, or *interpretes*, made application to all they met. This method of suing for offices was deemed allowable, and therefore never prohibited by law; but to restrain all undue influence, whether by bribery, or by exhibiting games, shows, and the like, many laws were enacted, and severe fines imposed.

AMBITUS, in music, a name sometimes appropriated to signify the particular extent of each tone, or modification of grave and acute.

AMBLE, in horsemanship, a peculiar pace by which a horse's two legs of the same side move at the same time.

Many methods have been proposed to bring a young horse to amble: some try it by new ploughed fields; some endeavour to bring him to amble from the gallop; and many use weights: some attempt to procure an amble in hand, ere they mount his back; others, by the help of hind shoes, made on purpose; others, by folding fine soft lists about the gambrels of the horse; and others by the tramel.

All these methods, however, are attended with great danger to the horse; and the best way is to try with the hand, by a gentle deliberate racking of the horse, by helping him in the weak part of the mouth with a smooth, big, and full snaffle, and correcting him first on one side, then on the other, with the calves of the legs, and sometimes with a spur.

AMBLYGON, in geometry, denotes an obtuse angled triangle, or a triangle, one of whose angles consists of more than ninety degrees.

AMBO, or AMBON, in ecclesiastical antiquity, a kind of pulpit, or reading desk, where that part of the divine service called the gradual was performed.

AMBROSE, or *St.* AMBROSE *in the wood*, an order of religious, who use the Ambrosian office, and wear an image of that saint engraven on a little plate: in other respects they conform to the rule of the Augustins.

AMBROSIA, the name of a distinct genus of plants, with flosculous flowers, composed of several small infundibuliform floscules, divided into five segments; these, however, are barren; the fruit, which in some measure resembles a club, growing on other parts of the plant.

This genus belongs to the monoecia pentandria class of Linnæus. The characters are: the male flowers are compound: the common calyx is a single leaved perianthium, the length of the florets; the compound corolla is uniform, tubular, flat, and hemispherical: the proper is monopetalous, funnel shaped, and quinquefid: the stamina consist of five very small filaments; the antheræ are erect, parallel, and pointed: the pistillum has a filiform stylus, the length of the stamina; the stigma, orbicular and membraneous: the receptaculum is naked. Female flowers below the male ones, on the same plant, doubled: the calyx is a single leaved perianthium, entire, with the belly quinquedentated, one flowered, and persistent: there is no corolla: the pistillum has an ovate germen in the bottom of the calyx; a filiform stylus, the length of the calyx; and two long bristly stigmata: the pericarpium is an ovate uniocular nut; the seed is single and roundish. Of this genus five species are enumerated; one of which is perennial, and may be propagated either by cuttings or by seeds. The plants are moderately hardy, so may be exposed to the open air in the summer; and in winter may be sheltered in a common green house with myrtles, and other hardy exotic plants.

AMBROSIAN OFFICE, in church history, a particular formula of worship in the church of Milan, which takes its name from St. Ambrose, who instituted that office in the fourth century. Each church originally had its particular office; and when the pope in after times took upon him to impose the Roman office upon all the western churches, that of Milan sheltered itself under the name and authority of St. Ambrose, from which time the Ambrosian ritual has prevailed in contradistinction from the Roman ritual.

AMBROSIAN *chant*, in ecclesiastical music, differs very little, if at all, from the Gregorian chant.

AMBROSIN, a coin formerly struck by the dukes of Milan, representing St. Ambrose on horseback, with a whip in his right hand.

AMBROSINIA, a genus of the class and order of gynandria polyandria. The essential character is, spathe one leaved, separated by a partition; stamina on the inner, pistils on the outer side of it. We know of but one species, a native of Sicily. It requires the protection of a green house in this country.

AMBRY, a place in which are deposited all utensils necessary for housekeeping.

In the ancient abbies and priories, there was an office under this denomination, wherein were laid up all charities for the poor.

AMBUBAJÆ, in Roman antiquity, were immodest women who came from Syria to Rome, where they lived by prostitution, and by playing on the flute: the word is derived from the Syriac *abbub*, which signifies a flute; although others make it come from *am* and *Baiæ*, because these prostitutes often retired to Baiæ. According to Cruquius, these women used likewise to sell paint for ornamenting the face, &c.

AMBULANT, the name of brokers, or exchange agents, who have not been sworn before magistrates. They transact brokerage business, but their testimony is not admitted in the courts of justice.

AMBULATION, in surgery, a term given to the spreading of a gangrene or mortification.

AMBULATORY, a term applied to such courts as were not fixed, but removed sometimes to one place, sometimes to another: thus the court of parliament and court of king's bench were formerly ambulatory.

Ambulatory will, is such a will as can be at any time revoked before the person's death.

AMBULIA, a genus of the didynimia angiospermia class and order. It grows in Malabar, has an aromatic smell, and is administered in cases of fever in the form of a decoction.

AMBURBIUM, in Roman antiquity, a procession made by the Romans round the city and pomærium, in which they led a victim, and afterward sacrificed it, in order to avert some calamity that threatened the city.

AMBURY, or Anbury, among farriers, denotes a tumour, wart, or swelling, which is soft to the touch and full of blood. See Farriery.

AMBUSTA, a term used in surgery for a solution of continuity, caused by the application of heated substances.

AME, a musical term used by the French to denote feeling and expression.

AMEDIANS, in church history, a congregation of religious in Italy, so called from their professing themselves *amantes Deum*, lovers of God; or rather, *amati Deo*, beloved of God.

AMELLUS, *starwort*, a genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ oppositifoliæ. The characters are: the common calyx is imbricated and roundish: the compound corolla is radiated; the hermaphrodite corollets numerous in the disk; the female numerous in the ray: proper corolla of the hermaphrodites are tubular and quinquefid; of the females, tongued, loose, and two or three toothed: the stamina in the hermaphrodites consist of five short capillary filaments; the antheræ cylindric and tubular: the pistillum has an ovate germen, a filiform stylus the length of the stamina, and two filiform stigmata: there is no pericarpium, but the calyx unchanged: the seeds are ovate and solitary; the pappus is hairy; the receptaculum chaffy. Of this there are two species, *viz.* Amellus lynchnitis, with one flower on each foot stalk. This is a native of the Cape of Good Hope, and a perennial plant. The amellus umbellatus, with flowers growing in umbels, is a native of Jamaica, and is extremely tender.

AMEN, in scriptural language, a solemn formula, or conclusion to all prayer, signifying *so be it*.

The term *amen* is Hebrew, being derived from the verb *aman*, *i.e.* to be true, faithful, &c. so that, strictly speaking, it signifies truth; and, used adverbially, as is frequently done in the Gospels, truly or verily. Sometimes it is repeated twice together, and then it stands for the superlative, as Amen, amen, dico vobis.

AMEND, or Amende, in the French customs, a pecuniary punishment imposed by a judge for any crime, false prosecution, or groundless appeal.

Amende honourable, an infamous kind of punishment inflicted in France upon traitors, parricides, or sacrilegious persons, in the following manner: the offender being delivered into the hands of the hangman, his shirt is stripped off, and a rope put about his neck, and a taper in his hand; then he is led into court, where he must beg pardon of God, the king, the court, and his country. Sometimes the punishment ends here, but sometimes it is only a prelude to death, or banishment to the gallies.

AMENDMENT, in law, the correction of an error committed in a process, which may be amended after judgment, unless the error lies in giving judgment, for in that case it is not amendable, but the party must bring a writ of error.

A bill may be amended on the file at any time before the plea is pleaded, but not afterward, without motion and leave of the court.

Amendment *of a bill*, in parliament, is some alteration made in the first draught of it. We even read of amendments. However, it is to be observed, that all amendments ought to be made in the house, whence the the thing to be amended originally proceeded.

Amendment, in husbandry, is used for the enriching land by laying manure on it.

AMENTACEOUS, in botany, an appellation given to such flowers as have an aggregate of summits hanging down in form of a rope, or cat's tail, which is called an amentum or catkin.

AMENTUM, in Roman antiquity, a thong tied about the middle of a javelin or dart, and fastened to the fore finger, in order to recover the weapon as soon as it was discharged. The ancients made great use of the amentum, thinking it helped to enforce the blow. Amentum also denotes a latchet that bound their sandals.

AMERCEMENT, or Amerciament, in law, a pecuniary punishment imposed upon offenders at the mercy of the court.

Amercements differ from fines, the latter being certain punishments growing expressly from some statute, whereas the former are imposed in proportion to the fault. Besides, fines are assessed by the court, but amercements by the country.

A court of record only can fine, all others can only amerce.

Sheriffs are amerciable for the faults of their officers, and clerks of the peace may be amerced in the king's bench for gross faults in indictments removed to that court.

A town is subject to amercement for the escape of a murderer in the day time; and if the town is walled, it is

subject to amercement whether the escape happens by day or night.

The statute of Magna Charta ordains that a freeman is not to be amerced for a small fault, but in proportion to the offence, by his peers and equals.

AMERICA, one of the four grand divisions of the earth. See GEOGRAPHY.

AMERIMNUM, a genus of the diadelphia decandria class and order, of the natural order of the papilionaceæ or leguminosæ. The essential character is, calyx two lipped; legume compressed, leafy, two valved, gaping; seeds few and solitary. There are two species: the one a shrub; and the other, A. ebenus, a tree which rises to 14 feet high, with a very thick stem. It is common in the West Indies, where the wood is cut and sent to England under the name of ebony.

AMETHYST, *amethystus*, in the history of precious stones, a gem of a purple colour, which seems compounded of a strong blue and a deep red; and according as either of these prevails, affording different tinges of purple, sometimes approaching to violet, and sometimes even fading to a pale rose colour.

The amethyst on analysis is found, according to Rose, to contain

97.50	silica
0.25	alumina
0.50	oxyde of iron and manganese
98.25	

Though the amethyst is generally of a purple colour, it is nevertheless sometimes found naturally colourless, and may at any time be easily made so by putting it into the fire; in which pellucid or colourless state, it so well imitates the diamond, that its want of hardness seems the only way of distinguishing it.

Some derive the name amethyst from its colour, which resembles wine mixed with water; whilst others, with more probability, think it got its name from its supposed virtue of preventing drunkenness; an opinion which, however imaginary, prevailed to that degree among the ancients, that it was usual for great drinkers to wear it about their necks.

Be this as it will, the amethyst is scarcely inferior to any of the gems in the beauty of its colour; and in its purest state is of the same hardness, and at least of equal value with the ruby and sapphire. It is found of various sizes, from that of a small vetch, to an inch and a half in diameter, and often to much more than that in length. Its shape is extremely various, sometimes roundish, sometimes oblong, and at others flatted, at least on one side; but its most common appearance is in a crystalliform figure, consisting of a thick column, composed of four planes, and terminated by a flat and short pyramid, of the same number of sides; or else, of a thinner and longer hexangular column, and sometimes of a long pyramid without any column. It makes the gayest figure in the last of these states, but is hardest and most valuable in the roundish and pebble like form.

The amethyst is found in the East and West Indies, and in several parts of Europe; the oriental ones, at least some of the finer specimens, being so hard and bright as to equal any of the coloured gems in value. However, by far the greater number of amethysts fall infinitely short of these, as all the European ones, and not a few of those brought from the East and West Indies, are very little harder than common crystal.

AMETHYST, in heraldry, a term for the purple colour in the coat of a nobleman, in use with those who blazon by precious stones instead of metals and colours. This in a gentleman's escutcheon is called Purpure, and in those of sovereign princes, Mercury.

AMETHYSTEA, a genus of the diandria monogynia class and order, of the natural order of verticillatæ and labiatæ. The characters are: the calyx consists of a single leaved perianthium, bell shaped, angular, semiquinquefid, and persistent: the corolla is monopetalous; the border quinquepartite, the lowest division more expanding: the stamina consist of two slender filaments approximated: the antheræ are simple and roundish: the pistillum has a four cleft germen; stylus, the size of the stamina; stigmata two, acute: no corolla: the seeds four, gibbous, and shorter than the calyx. There is only one known species: it is a native of Siberia. It is an annual plant, with an upright stalk, which rises about a foot high. Toward the top it puts forth two or three small lateral branches, garnished with small trifid leaves, sawed on their edges, of a very dark green colour. The flowers appear in June or July, and are produced in small umbels at the extremities of the branches. They are of a fine blue colour, as are also the upper part of the branches, and the leaves immediately under the umbel, so that they make a fine appearance. The seeds of the amethystea should be sown in autumn, as they are apt to remain a whole year in the ground.

AMETHYSTINE, a term applied to a kind of purple garment dyed of the hue of amethyst. This colour is a medium between the tyrian and hyacinthine.

AMIABLE, or AMICABLE *numbers*, such as are mutually equal to the sum of one another's aliquot parts, as the numbers 284 and 220. Thus the aliquot parts of 220, are 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110, and these added together are equal to 284; and the aliquot parts of 284, are 1, 2, 4, 71, 142, and these added together are equal to 220.

Van Schouten was the first who gave this name to such numbers, of which it is easily apprehended, there are but very few at least to be set down and manageable by us; for 284 and 220 are the two least, and the two next greater are 18416 and 17296; the third pair of numbers are 9363584 and 9437056.

AMIANTHUS, a fibrose, flexile, and elastic mineral substance, composed of short and abrupt filaments.

There are several species of amianthi; that of a grayish green colour, with short, abrupt, and interwoven filaments, is the same with the plumose alum of the shops.

The properties of the amianthus are very wonderful. They will neither give fire with steel, nor ferment with aquafortis; and if thrown into the fire, will endure the most extreme heat without the least injury to their texture. Amianthus threads are sometimes used as perpetual wicks for lamps; they require occasional cleaning from the soot; and by great heat they are apt to run together in a state of semifusion, so as to prevent the due supply of oil. The amianthus and all the varieties of asbestos, are classed by Mr. Kirwan among the magnesian

cloths, as they contain about a fifth part of that substance. See Asbestos and Mineralogy.

AMICABLE benches, in Roman antiquity, were, according to Pitiscus, lower and less honourable seats allotted for the inferior judges, who, upon being admitted of the emperor's council, were dignified by him with the title *amici*.

AMICTUS, among ecclesiastical writers, the uppermost garment anciently worn by the clergy; the other five being the alba, singulum, stola, manipulus, and planeta. The amictus was a linen garment, of a square figure, covering the head, neck, and shoulders, and buckled, or clasped, before the breast. It is still worn by the religious abroad.

AMICULUM, in Roman antiquity, a woman's upper garment, which differed from the palla, as we learn from Livy; but in what that difference consisted we are at a loss to know, unless that it was shorter than the palla. The amiculum was worn both by matrons and courtesans.

AMICUS curiæ, a law term, to denote a bystander, who informs the court of a matter in law that is doubtful or mistaken.

AMIESTIES, cotton cloths, which come from the East Indies.

AMIRANTE, in the Spanish polity, a great officer of state, answering to our lord high admiral.

AMITTERE legem terræ, among lawyers, a phrase importing the loss of the liberty of swearing in any court. The punishment of a champion overcome or yielding in battle, of jurors found guilty in a writ of attaint, and of a person outlawed.

AMMAN, or Ammant, in the German and Belgic policy, a judge who has the cognisance of civil causes.

Ammant is also used among the French for a public notary, or officer who draws up instruments and deeds.

AMMANNIA, in botany, the name of a genus of plants, belonging to the tetrandria monogynia class and order of Linnæus; the flower of which is composed of four oval patent petals growing within the cup; and its fruit is a roundish capsule covered by the cup, and containing four cells; and this description forms its essential character. There are seven species, all of which seem to be annual, and being natives of hot climates most of them require protection in this country.

AMMI, *bishop's weed*, in botany, a genus of umbelliferous plants, belonging to the pentandria digynia class and order of Linnæus; the flower of which is rosaceous and composed of heart like petals; and its fruit is a small roundish and striated capsule, containing two striated seeds, convex on one side. There are three species, all annual.

AMMOCHRYSOS, in natural history, the name of a stone common in Germany, being a species of mica, with gold coloured spangles. Reduced to powder, it is used to strew over writing.

AMMODYTES, the name of a genus of fishes, of which only a single species has hitherto been discovered. The head is compressed, narrower than the body; upper lip doubled, lower jaw narrow and pointed; teeth sharp; gill membrane of seven rays; body long square; tail fin distinct. It inhabits the sandy shores of the northern seas, and it takes its name from its quality of diving into, or burying itself under the sand. It is usually from nine to twelve inches in length. It is silvery white, and greenish on the back.

AMMONIA, or Volatile Alkali, is distinguished from the fixed alkalies by a very sharp irritating pungent smell, and by its great volatility.

Ammonia may be procured by the following process:

1. Put into a retort a mixture of three parts of quick lime and one part of sal ammoniac in powder. Plunge the beak of the retort below the mouth of a glass jar filled with mercury, and standing inverted in a basin of mercury. Apply the heat of a lamp to the retort; a gas comes over, which displaces the mercury and fills the jar. This gas is ammonia. It was known by the name of volatile alkali; it was also called hartshorn, because it was often obtained by distilling the horn of the hart; spirit of urine, because it may be obtained by the same process from urine; and spirit of sal ammoniac, because it may be obtained from that salt. Dr. Black first pointed out the difference between ammonia and carbonat of ammonia, or ammonia combined with carbonic acid; and Dr. Priestley discovered the method of obtaining it in a state of purity, by the process already described.

2. Ammonia in the state of gas is transparent and colourless like air; its taste is acrid and caustic like that of the fixed alkalies, but not nearly so strong, nor does it, like them, corrode those animal bodies to which it is applied: its smell is remarkably pungent, though not unpleasant when sufficiently diluted. Its use as a stimulant to prevent fainting is well known.

Animals cannot breathe it without death. When a lighted candle is let down into this gas, it goes out three or four times successively; but at each time the flame is considerably enlarged by the addition of another flame of a pale yellow colour, and at last this flame descends from the top of the vessel to the bottom.

Its specific gravity is 0.000732. Its weight is to that of common air as 3 to 5.

When exposed to a cold of —45° it is condensed into a liquid, which again assumes the gaseous form when the temperature is raised. When passed through a red hot tube of porcelain or glass, it is totally decomposed and converted into hydrogen and azotic gas. That this experiment may succeed, the diameter of the tube must not be too great.

3. It combines very rapidly with water. When a piece of ice is brought into contact with this gas, it melts and absorbs the ammonia, while at the same time its temperature is diminished. Cold water absorbs this gas almost instantaneously, and at the same time heat is evolved, and the specific gravity of the water is diminished. Water is capable of absorbing and condensing more than a third of its weight of ammoniacal gas. The specific gravity of the saturated solution is 0.9054. It is in this state that ammonia is usually employed by chymists. The term ammonia, indeed, almost always means this liquid solution of ammonia in water. When heated to the temperature of about 130°, the ammonia separates under the form of gas. When exposed to the temperature of —46° it crystallizes; and when suddenly cooled down to —68°, it assumes the appearance of a thick jelly, and has scarcely any smell.

It follows from the experiments of Mr. Davy, that a saturated solution of ammonia is composed of

74.63 water
25.37 ammonia

100.00

The following table, drawn up by the same ingenious chymist, exhibits the proportion of water and ammonia contained in 100 parts of liquid ammonia of different specific gravities.

Specific grav.	Ammonia.	Water.
0.9054	25.37	74.63
0.9166	22.07	77.93
0.9255	19.54	80.46
0.9326	17.52	82.48
0.9385	15.88	84.12
0.9435	14.53	85.47
0.9476	13.46	86.54
0.9513	12.40	87.60
0.9545	11.56	88.44
0.9573	10.82	89.18
0.9597	10.17	89.83
0.9619	9.60	90.40
0.9684	9.50	90.50
0.9639	9.09	90.91
0.9713	7.17	92.83

4. Ammoniacal gas is not altered by light; but when electric sparks are made to pass through it, the bulk of the gas is considerably increased, and it is converted into hydrogen gas and azotic gas. Hence it follows, that it is composed of hydrogen and azote. By this process Berthollet converted 1.7 cubic inches of ammoniacal gas into 3.3 cubic inches.

5. This gas has no effect upon oxygen gas while cold; but when a mixture of the two gases is made to pass through a red hot porcelain tube, a detonation takes place, water is formed, and azotic gas is emitted. Hence we see that ammonia is partly combustible. Its hydrogen combines with the oxygen, and forms water, while the azote makes its escape in the form of a gas. If the proportion of oxygen gas is considerable, nitric acid is also formed in consequence of the combination of the azote with the superabundant oxygen. The same decomposition and detonation take place if common air is used instead of oxygen gas.

6. Sulphur is the only one of the simple combustibles that combines with ammonia. Hydrogen produces no change upon it whatever; but phosphorus and charcoal act with considerable effect in high temperatures.

It combines with sulphur in the state of vapour, and forms a sulphuret which decomposes water, and forms hydrogenated sulphuret of ammonia, known formerly by the name of fuming liquor of Boyle, because it was first described by that philosopher. It is commonly prepared by distilling a mixture of five parts of sal ammoniac, five parts of sulphur, and six of quick lime. It is a liquid of a red or rather deep orange colour, and exhales a fetid odour in consequence of an excess of ammonia which it contains. Its nature was first pointed out by Berthollet.

Phosphorus produces no change on ammoniacal gas while cold; but when this gas is made to pass through phosphorus in a red hot porcelain tube, it is decomposed, and phosphureted hydrogen gas, and phosphureted azotic gas, are formed.

Charcoal absorbs ammoniacal gas, but does not alter its properties while cold. But when the gas is made to pass through red hot charcoal, part of the charcoal combines with it, and forms a substance known by the name of prussic acid.

7. Ammonia is not acted on by azote; but it combines rapidly with muriatic acid, the two gases concreting into the solid salt called muriat of ammonia.

8. Ammonia does not combine with the metals; but it changes some of them into oxides, and then dissolves them. The oxidizement is evidently in consequence of the decomposition of part of the water with which the ammonia is combined; for hydrogen gas is emitted during the solution. Copper and zinc are oxidized by the action of ammonia: as are also tin and iron, though only superficially. Scarcely any of the other metals are altered by its action.

Liquid ammonia is capable of dissolving the oxides of copper, iron, tin, nickel, zinc, bismuth, and cobalt. When digested upon the oxides of mercury, lead, or manganese, it is decomposed, water is formed by the union of the hydrogen of the ammonia with the oxygen of the oxides, and azotic gas is emitted. If a considerable heat is applied, nitric acid is formed at the same time with water. Several other oxides are also partly deoxidized when ammonia is poured into their solutions in acids. The ammoniacal solution of the peroxide of copper is of a fine blue colour, and, according to Sage, capable of crystallizing. When heat is applied, the ammonia is partly driven off, and partly decomposed, by the combination of its hydrogen with the oxygen of the oxide.

9. Ammonia combines readily with the peroxides of gold and silver, and forms with them two compounds, formerly known by the names of fulminating gold and fulminating silver; because when heated or rubbed, they explode with great violence. It combines also with the red oxide of mercury.

10. The affinities of ammonia are the same with those of the fixed alkalies.

11. As ammonia has the property of detonating with nitre, chymists had unanimously agreed that it contained phlogiston. Scheele first demonstrated, that when it is decomposed by means of the oxides of manganese, arsenic, or gold, azotic gas is set at liberty, while the oxide is reduced. Hence he concluded, that it was composed of azote and phlogiston; and Bergmann coincided with him in opinion. Dr. Priestley discovered, that when electric explosions are made to pass through this gas, its bulk is gradually augmented to thrice the space which it formerly occupied; and a quantity of hydrogen gas is produced. The same ingenious philosopher applied heat to the red oxides of mercury and lead confined in ammoniacal gas. The oxides were reduced, water was evolved, the ammoniacal gas disappeared, and instead of it, there was found a quantity of azotic gas. These experiments, and those of Scheele, led to the conclusion, that ammonia is composed of azote and hydrogen; a conclusion which was fully established by the experiments of Berthollet, published in the Memoirs of the French Academy for 1785. This acute philosopher repeated the experiments of Scheele and Priestley, and applied to them the theory of

Mr. Lavoisier, and added also several very decisive ones of his own. The most important of these is the mutual decomposition of ammonia and oxymuriatic acid. When solutions of these bodies in water are mixed together, an effervesence takes place, azote is disengaged, a quantity of water formed, and the oxymuriatic acid is converted into common muriatic acid. Now the substances mixed were ammonia and oxymuriatic acid, which is composed of oxygen and muriatic acid; the products were, muriatic acid, azote, and water, which is composed of oxygen and hydrogen. The oxygen of the water was furnished by the acid; the other products must have been furnished by the ammonia, which had disappeared. Ammonia, therefore, must be composed of azote and hydrogen. It follows from Mr. Berthollet's experiments, that ammonia is composed of 121 parts of azote and 29 of hydrogen. According to Dr. Austin, it is composed of 121 parts of azote and 32 of hydrogen. Hence 100 parts of ammonia are composed of about 80 parts of azote and 20 of hydrogen. The experiments of Berthollet have been still further confirmed by those made more lately by Mr. Davy.

AMMONIA, *liquid*, is formed by the solution of ammoniacal gas in water, which takes place very rapidly.

AMMONIAC, or *Gum* AMMONIACUM, in the materia medica, a gum, or more properly a gum resin, extracted from an umbelliferous plant, growing in some parts of Africa and Asia. It is brought to us in drops or granules, and sometimes in large masses, composed of a number of these granules connected together by other matter of the same kind.

The best ammoniac is always most free from dross, of a yellowish colour without and white within, of a bitterish taste and castor smell.

AMMONIAC, *sal.* See *Muriate of Ammonia*, in CHYMISTRY.

AMMONIACAL gas, an elastic fluid, as transparent as air, but little more than half as heavy. Its smell and taste are sharp and caustic. It destroys animal and vegetable life, and extinguishes flame. The electric spark separates it into its constituent principles, hydrogen and azotic gas. On being mixed with acid gases, clouds are produced by the formation of neutral ammonial salts.

AMMONIACAL preparations. See PHARMACY.

AMMONITÆ, in natural history, the same with the cornua ammonis, or snake stones.

AMMOSCHISTA, a genus of stones of a laminated structure, and splitting only horizontally, or into flat plates.

AMMUNITION, a general term for all warlike provisions, but more especially powder, ball, &c.

Ammunition, arms, utensils of war, gunpowder, imported without license from his majesty, are, by the laws of England, forfeited and triple the value.

And again, such license obtained, except for furnishing his majesty's public stores, is to be void, and the offender to incur a premunire, and be disabled from holding any office from the crown.

AMMUNITION BREAD, SHOES, &c. such as are served out to the soldiers of an army or garrison.

AMNIOS, a thin pellucid membrane, which surrounds the fetus. See ANATOMY and PHYSIOLOGY.

AMOEBŒUM, a poem, or rather composition, in which two parties speak alternately in the same number of verses, but so as that he who answers, either goes beyond or contradicts the other; such are the third and seventh Eclogues of Virgil.

AMOGABARI, ancient Spanish soldiery greatly celebrated for bravery.

AMOGLOSSUS, a name of a peculiar kind of flat fish, something resembling a soal, and called also a lantern.

AMOK, a term used as a catch word among the slaves in Batavia; who, when they consider themselves as aggrieved, sally forth, shouting out *amok, amok*, and murder all they meet.

AMOMUM, a genus of the *monandria monogynia* class and order. The characters are: the calyx is an obscure three toothed perianthium, above: the corolla is monopetalous, the tubes short, the limbus tripartite: the stamina is an oblong filament, with the anthera adjoining; the pistillum has a roundish germen, beneath; the style is filiform, the stigma obtuse; the pericarpium is leathery, subovate, trigonous, trilocular, and three valved; the seeds are numerous. Of this genus there are 12 species, the principal of which are,

1. Amomum Zinziber, or common ginger, a native of the East, and also of some parts of the West Indies; where it grows naturally without culture. The roots are jointed, and spread in the ground; they put out many green, reed like stalks in the spring, which rise to the height of two feet and a half, with narrow leaves. The flower stems rise by the side of these immediately from the root: these are naked, ending with an oblong scaly spike. From each of these scales is produced a single blue flower, whose petals are but little lower than the squamous covering. All the species are tender, and require a stove to preserve them in this country. They are easily propagated by parting the roots in the spring.

2. Amomum Zerumbet, or wild ginger, also a native of India. The roots are larger than those of the common ginger, but are jointed in the same manner. The stalks grow from three to near four feet high, with oblong leaves placed alternately. The flower stems arise immediately from the root: these are terminated by oblong, blunt, scaly heads; out of each scale is produced a single white flower, whose petals extend a considerable length beyond the scaly covering.

3. Amomum Cardamomum, or cardamom, is a native of India, but is little known in this country except by its seeds, which are used in medicine. Of this there is a variety, with smaller fruit, which makes the distinction into cardamomum majus and minus.

4. Amomum Grana Paradisi, is likewise a native of the East Indies. The fruit containing the grains of paradise is about the size of a fig, divided into three cells, in each of which are contained two small seeds like cardamoms. They are somewhat more grateful, and considerably more pungent, than cardamoms.

The dried roots of the 1st species are of great use in the kitchen, as well as in medicine. They furnish a considerable export from some of the American islands. The green roots, preserved as a sweetmeat, are preferable to every other. The Indians mix them with their rice, which is their common food, to correct its natural insipidity. Ginger is a very useful spice in cold flatulent colics, and in laxity and debility of the intestines: it does not heat so much as those of the pepper kind, but its effects are much

more durable. The cardamoms and grains of paradise have the same medicinal qualities with ginger.

AMOMUM, in the materia medica, a name given to the seed of an aromatic plant, esteemed a powerful diuretic, and aperient; and consequently thought good in nephritic cases, obstructions of the viscera, and suppression of the menses. It is now disused.

AMOPHILA, a name proposed for a new genus of hymenopterous insects, with beak conic, inflected, concealing a bifid, retractile, tubular tongue.

AMORPHA, in botany, a genus of plants, belonging to the diadelphia decandria class and order of Linnæus; the flower of which consists of one petal vertically ovated, hollow and erect; and the fruit is a lupulated pod, of a compressed form, and covered with tubercles, in which are contained two seeds, of an oblong kidney like shape. The essential character is: standard of the corolla ovate, concave: wings none, calyx none. We know of but one species, a very elegant shrub, vulgarly called bastard indigo, as formerly in Carolina a coarse sort of indigo was made from the young shoots. With us it is perfectly hardy.

AMORTIZATION, in law, the alienation of lands or tenements to a corporation or fraternity and their successors.

Amortization also denotes the privilege of taking lands, &c. in mortmain, for which purpose the king's consent must first be obtained. This license is granted upon paying to the king and the superior a certain sum to indemnify them for several incidental dues, which in the common way would have fallen to them, but by the amortization are cut off.

AMPELIS, in zoology, the chatterer, a genus of birds belonging to the order of passeres; the distinguishing characters of which are, that the tongue is furnished with a rim or margin all round, and the bill is conical and straight. There are seven species, all natives of foreign countries, except the garrulus, which is a native both of Europe and the West Indies. In the former, the native country of these birds is Bohemia; whence they wander over the rest of Europe, and were once superstitiously considered as presages of a pestilence. They appear annually about Edinburgh in February, and feed on the berries of the mountain ash. They also appear as far S. as Northumberland; and, like the field fare, make the berries of the white thorn their food. It is but by accident that they ever appear further south. They are gregarious; feed on grapes, where vineyards are cultivated; are easily tamed, and are esteemed delicious food. This species is about the size of the blackbird; the bill is short, thick, and black; on the head is a sharp pointed crest reclining backward; the lower part of the tail is black, the end of a rich yellow; the quill feathers are black, the three first are tipped with white, the six next have half an inch of their exterior margin edged with fine yellow, the interior with white. But what distinguishes this from all other birds, are the thorny appendages from the tips of seven of the secondary feathers, of the colour and gloss of the best red wax. See Plate, Nat. Hist. fig. 15*, 16*.

AMPELITES, Cannel coal, in natural history, a solid, dry, opaque fossil, very hard, not fusible, but easily inflammable, and burning with a bright, vivid, white flame. This mineral is found in Lancashire, and in different parts of Scotland, where it is known by the name of *Parrot coal*. Colour black; structure sometimes slaty. It burns like a candle, and lasts but a short time. It does not cake, and leaves a stony or sooty residuum.

A specimen of Lancashire cannel coal, analyzed by Mr. Kirwan, contained

75.20 charcoal
21.68 maltha
3.10 alumina and silica

99.98

Cannel coal is susceptible of polish, and, like jet, is frequently wrought into snuff boxes, and other trinkets.

AMPHERES, in antiquity, a kind of vessels, wherein the rowers plied two oars at the same time, one with the right hand, and the other with the left.

AMPHIARTHROSIS, in anatomy, a term under which some comprehend all those junctures of the bones, which have a manifest motion, and which differ from the several articulations of the diarthrosis either in regard to their figure or motion.

AMPHIBIA, the third class of animals in the Linnæan system, including those which possess, in a certain degree, the power of respiration, and are thereby enabled to live either in water or on land. This class is subdivided into four orders, *viz.* 1st, Amphibia reptiles, 2d, Amphibia serpentes, 3d, Amphibia nantes, and 4th, Amphibia meantes. The distinguishing characters of this class are these; they have either naked or scaly bodies, and sharp pointed fore teeth, but without grinders, or *dentes molares:* to which add, that they have no radiated fins. The class includes the tortoise, the frog kind, and the lizard and serpent kinds: 289 species.

Anatomists observe, that the lungs of amphibious animals are so formed, that though respiration is necessary to them, yet it is not requisite to be performed at short intervals. Hence it is, that they can remain a long time under water without being suffocated, and many of them even a considerable part of their lives.

AMPHIBIOUS, a term descriptive of the class *Amphibia;* it also applies, however, to the otter, seal, beaver, and some animals of the other classes, who live on the land, and occasionally go into the water in search of prey.

Most of the *amphibious* animals of this description have peculiar provisions in their structure to fit them for their mode of living, particularly in the heart, lungs, foramen ovale, &c. There are two very curious and important disquisitions by Dr. Parsons on this subject, in the 56th vol. of the Phil. Trans. the substance of which is as follows. Dr. Parsons classes amphibious animals under two divisions: 1. Such as enjoy their chief functions by land, but occasionally go into the water. 2. Such as chiefly inhabit the water, but occasionally go on shore.

Of the first he particularly considers the phocæ or seal tribe; and endeavours to show, that none of them can live chiefly in the water, but that their chief enjoyment of the functions of life is on shore. These animals, he observes, are really quadrupeds; but as their chief food is fish, they are under the necessity of going out to sea to hunt their prey, and to great distances from shore; taking care that, however great the distance, rocks or small islands are at hand, as resting places when they are tired, or when their bodies become too much macerated in the

water. He proceeds: It is well known, that the only essential difference, as to the general structure of the heart, between amphibious and mere land animals, or such as never go into the water, is, that in the former the oval hole remains always open. Now, in such as are without this hole, if they were to be immersed in water but for a little time, respiration would cease, and the animal must die. There are three necessary and principal uses of respiration in all land animals, and in those kinds that are counted amphibious. The first is, that of promoting the circulation of the blood through the whole body and extremities. In real fishes, the force of the heart is alone capable of sending the blood to every part, as they are not furnished with limbs or extremities; which being so remote from the heart, have need of such assistance, otherwise the circulation would be very languid in these parts. Thus we see, that in persons subject to asthmatic complaints, the circulation grows languid, the legs grow cold and œdematous, and other parts suffer by the defect in respiration. A second use of breathing is, that, in inspiration, the variety of particles, of different qualities, which float always in the air, might be drawn into the lungs, to be insinuated into the mass of blood, being highly necessary to contemperate and cool the agitated mass, and to contribute refined pabulum to the finer parts of it, which, meeting with the daily supply of chyle, serves to assimilate and more intimately mix the mass, and render its constitution the fitter for supporting the life of the animal. Therefore it is, that valetudinarians, by changing foul or unwholesome air for a free, good, open air, often recover from lingering diseases. A third principal use of respiration is, to promote the exhibition of voice in animals; which all those that live on the land do according to their specific natures. From these considerations it appears, that the phocæ of every kind are under an absolute necessity of making the land their principal residence. But there is another very convincing argument why they reside on shore the greatest part of their time, *viz.* that the flesh of these creatures is analogous to that of other land animals; and therefore, by over long maceration, added to the fatigue of their chasing their prey, they would suffer such a relaxation as would destroy them. It is well known, that animals which have lain long under water, are reduced to a very lax and even putrid state; and the phoca must bask in the air on shore. Let us now examine by what power these animals are capable of remaining longer under water than land animals. All these have the oval hole open between the right and left auricles of the heart, and in many the canalis arteriosus also; and while the phoca remains under water, which he may continue an hour or two, more or less, his respiration is stopped; and the blood, not finding the passage through the pulmonary artery free, rushes through the arterial canal, being a short passage to the aorta, and thence to every part of the body, maintaining the circulation; but upon rising to come ashore, the blood finds its passage again through the lungs the moment he respires. Thus the fœtus in utero, during its confinement, having the lungs compressed, and consequently the pulmonary arteries and veins impervious, has the circulation of the blood carried on through the oval hole and the arterial canal. Now so far the phoca in the water, and the fœtus in utero, are analogous; but they differ in other material circumstances. One is, that the fetus having never respired, remains sufficiently nourished by the maternal blood circulating through him, and continues to grow till the time of his birth, without any want of respiration, during nine months confinement; the phoca having respired the moment of his birth, cannot live very long without it, for the reasons given before; and this hole and canal would be closed in them, as it is in land animals, if the dam did not, soon after the birth of the cub, carry him so very frequently into the water to teach him; by which practice these passages are kept open during life, otherwise they would not be capable of attaining the food designed for them by Providence. Another difference is, that the phocæ, as was said before, would be relaxed by maceration in remaining too long in the water; whereas the fœtus in utero suffers no injury from continuing its full number of months in the fluid it swims in: the reason is, that water is a powerful solvent, and penetrates the pores of the skins of land animals, and in time can dissolve them; whereas the *liquor amnii* is an insipid soft fluid, impregnated with particles more or less mucilaginous, and utterly incapable of making the least alteration in the cutis of the fetus. Otters, beavers, and some kinds of rats, go occasionally into the water for their prey, but cannot remain very long under water. "I have often gone to shoot otters, says our author, and watched all their motions; I have seen one of them go softly from a bank into the river, and dive down; and in about two minutes rise, at 10 or 15 yards from the place he went in, with a middling salmon in his mouth, which he brought on shore: I shot him, and saved the fish whole." Now, as all fetuses have these passages open, if a whelp of a true water spaniel was, immediately after its birth, served as the phoca does her cubs, and immersed in water, to stop respiration for a little time every day, it is probable that the hole and canal would be kept open, and the dog be made capable of remaining as long under water as the phoca. Frogs, how capable soever of remaining in the water, yet cannot avoid living on land, for they respire; and if a frog is thrown into a river, he makes to the shore as fast as he can. The lizard kind, such as may be called water lizards, are all obliged to come to land, in order to deposite their eggs, to rest, and to sleep. Even the crocodiles, who dwell much in rivers, sleep and lay their eggs on shore; and, while in the water, are compelled to rise to the surface to breathe; yet from the texture of his scaly covering, he is capable of remaining in the water longer by far than any species of the phoca, whose skin is analogous to that of a horse or cow. The hippopotamus, who wades into the lakes or rivers, is a quadruped, and remains under the water a considerable time; yet his chief residence is upon land, and he must come on shore for respiration. The testudo, or sea tortoise, though he goes out to sea, and is often found far from land, yet being a respiring animal, cannot remain long under water. He has indeed a power of rendering himself specifically heavier or lighter than the water, and therefore can let himself down to avoid an enemy or a storm: yet he is under a necessity of rising frequently to breathe, for reasons given before; and his most usual situation while at sea, is upon the surface of the water, feeding upon the various substances that float in great abundance every where about him. These animals sleep

securely upon the surface, but not under water, and can remain longer at sea than any other of this class, except the crocodile, because, as it is with the latter, his covering is not in danger of being too much macerated.

The second division of amphibious animals, according to Dr. Parsons, comprehends such as chiefly inhabit the waters, but occasionally go on shore. These are but of two kinds; the eels, and water serpents, or snakes of every kind. It is their form that qualifies them for locomotion on the land, and they know their way back to the water at will; for by their structure they have a strong peristaltic motion, by which they can go forward at a pretty good rate; whereas all other kinds of fish, whether vertical or horizontal, are incapable of a voluntary locomotion on shore; and therefore, as soon as such fish are brought out of the water, after having flounced a while, they lie motionless, and soon die. Let us now examine into the reason why these vermicular fish, the eel and serpent kinds, can live a considerable time on land, and the vertical and horizontal kinds die almost immediately when taken out of the water; and, in this research, we shall come to know what analogy there is between land animals and those of the waters. All land animals have lungs, and can live no longer than while these are inflated by the ambient air, and alternately compressed for its expulsion; that is, while respiration is duly carried on, by a regular inspiration and expiration of air. In like manner, the fish in general have, instead of lungs, gills or bronchiæ: and as, in land animals, the lungs have a larger portion of the mass of blood circulating through them, which must be stopped if the air has not a free ingress and egress into and from them; so, in fish, there is a great number of blood vessels that pass through the bronchiæ, and a great portion of their blood circulates through them, which must in like manner be totally stopped, if the bronchiæ are not perpetually wet with water. So that, as the air is to the lungs in land animals, a constant assistant to the circulation; so is the water to the bronchiæ of those of the rivers and seas: for when these are out of the water, the bronchiæ very soon grow crisp and dry, the blood vessels are shrunk, and the blood is obstructed in its passage; so, when the former are immersed in water, or otherwise prevented from having respiration, the circulation ceases, and the animal dies. Again, as land animals would be destroyed by too much maceration in water, so fishes would, on the other hand, be ruined by too much exsiccation; the latter being, from their general structure and constitution, made fit to bear and live in the water; the former, by their constitution and form, to breathe and dwell in the air. But it may be asked, why eels and water snakes are capable of living longer in the air than the other kinds of fish? This is answered, by considering the providential care of the great Creator for these and every one of his creatures; for since they were capable of locomotion by their form, which they need not be if they were never to go on shore, it seemed necessary that they should be rendered capable of living a considerable time on shore, otherwise their locomotion would be in vain. How is this provided for? Why, in a most convenient manner; for this order of fishes have their bronchiæ well covered from the external drying air: they are also furnished with a slimy mucus, which hinders their becoming crisp and dry for many hours; and their very skins always emit a mucous liquor, which keeps them supple and moist for a long time; whereas the bronchiæ of other kinds of fish are much exposed to the air, and want the slimy matter to keep them moist. Now, if any of these, when brought out of the water, were laid in a vessel without water, they might be preserved alive a considerable time, by only keeping the gills and surface of the skin constantly wet, even without any water to swim in.

Some kinds of insects, and some birds, are amphibious. The term has been applied to men who have the faculty of living long under water. The divers employed in the pearl fisheries possess this power in an eminent degree.

AMPHIBOLOGY, in grammar and rhetoric, a term used to denote a phrase susceptible of two different interpretations.

AMPHIBRACHYS, in ancient poetry, the name of a foot consisting of three syllables, whereof that in the middle is long, and the other two short.

AMPHICTYONS, in Grecian antiquity, an assembly composed of deputies from the different states of Greece, and resembling, in some measure, the diet of the German empire.

The amphictyons met regularly at Delphi, twice a year, *viz.* in spring and autumn, and decided all differences between any of the Grecian states, their determinations being held sacred and inviolable.

AMPHIMACER, in ancient poetry, a foot consisting of three syllables, whereof the first and last are long, and that in the middle short.

AMPHIMASCALOS, a tunic, or coat, worn by the Greeks, with two short sleeves, so as to cover part of the arm to the elbow. The coats of freemen were *amphimascalos*, those of slaves had only one.

AMPHIBOLES, the principal magistrates of Syracuse, in Sicily, called archons at Athens.

AMPHIPPII, in Grecian antiquity, soldiers, who in war used two horses without saddles, and were dexterous enough to leap from one to the other.

AMPHIPRORÆ, in the naval affairs of the ancients, vessels with a prow at each end. They were used chiefly in rapid rivers and narrow channels, where it was not easy to tack about.

AMPHISBÆNA, in zoology, a genus of serpent, so called because it moves with either end forward. The body of the amphisbæna has a number of circular annuli, surrounding it from the head to the extremity of the tail; so that it seems composed of a number of narrow and somewhat rounded rings applied close to one another, and having deep furrows between them.

Only two species of this genus have hitherto been discovered, the white and the black. The white is from 15 to 18 inches long; it is found preying on insects, worms, &c. It is harmless, but on handling it, the skin becomes affected with a slight itching, accompanied with small pustules. The other is rarely so large, and is equally harmless. The skin of the amphisbæna is strong and tenacious, and of a smooth glossy surface; and it is probable that they are enabled with facility to perforate the ground in the manner of earth worms, in order to obtain occasional supplies of food. See Nat. Hist. fig. 14*.

AMPHISCII, among geographers, a name applied to the people who inhabit the torrid zone.

Amphiscii, as the word imports, have their shadows one part of the year toward the north, and at the other toward the south, according to the sun's place in the ecliptic. They are also called Ascii.

AMPHITAPA, in antiquity, a garment frized or shagged on both sides, which was laid under persons going to sleep.

AMPHITHEATRE, in antiquity, a spacious edifice built either round or oval, with a number of rising seats, upon which the people used to sit and behold the combats of gladiators, of wild beasts, and other sports.

Amphitheatres were at first only of wood, and it was not till the reign of Augustus, that Statilius Taurus built one for the first time of stone. The lowest part was of an oval figure, and called arena, because, for the conveniency of the combatants, it was usually strewed with sand; and round the arena were vaults styled *caveæ*, in which were confined the wild beasts appointed for the shows. Above the caveæ was erected a large circular peristyle podium, adorned with columns. This was the place of the emperors, senators, and other persons of distinction. The rows of benches were above the podium. Their figure was circular, and they were entered by avenues, at the end of which were gates, called vomitoriæ. The most perfect remains we now have of ancient amphitheatres are that of Vespasian, called the coliseum, that at Verona in Italy, and that at Nismes in Languedoc.

AMPHORA, in antiquity, a liquid measure in use among the Greeks and Romans. The Roman amphora contained forty-eight sextaries, and was equal to about seven gallons one pint, English wine measure; and the Grecian, or attic amphora, contained one third more.

Amphora, was a dry measure, likewise in use among the Romans, and contained three bushels.

Amphora, among the Venetians, the largest measure used for liquids. It contains four bigorzas, the bigorza being four quarts, the quart four sachies, and each sachie four leras; but by wholesale the amphora is 14 quarts, and the bigorza three quarts and a half.

AMPHORARIUM *vinum*, wine that is drawn into pitchers, distinguished from cask wine. The Romans had a method of keeping wine in amphoræ for many years to ripen, by fastening the lids down with pitch or gypsum, and placing them either under ground, or in the smoke.

AMPHOTEROPLON, a kind of naval insurance, where insurers run the risk both in the going out, and return of the vessel.

AMPHOTIDES, in antiquity, a kind of armour or covering for the ears, worn by the ancient pugilists, to prevent their adversaries from laying hold of this part.

AMPLIATION, in Roman antiquity, was the deferring to pass sentence in certain causes. This the judge did, by pronouncing the word *amplius;* or by writing the letters N. L. for *non liquet;* thereby signifying, that as the cause was not clear, it would be necessary to bring further evidence.

AMPLITUDE, an arch of the horizon intercepted between the east or west point, and the centre of the sun, or a planet at its rising and setting, and so is either north and south, or ortive and occasive.

The sun's amplitude, either rising or setting, is found by the globes, by bringing the sun's place to the horizon, either on the east or west side, and the degrees from the east point, either north or south, are the amplitude required. To find the amplitude trigonometrically, say, as the cosine of the latitude: radius:: sine of the present declination: sine of the amplitude. This problem is useful in navigation, to find the variations of the compass.

Amplitude *Magnetical*, the different rising or setting of the sun, from the east or west points of the compass. It is found by observing the sun, at his rising and setting, by an amplitude compass.

Amplitude *of the range of a projectile*, the horizontal line, subtending the path in which the projectile moved.

AMPULLA, in antiquity, a round big bellied vessel, which the ancients used in their baths, to contain oil for anointing their bodies. Ampulla was also a cup made of glass, and sometimes of leather, for drinking out of at table.

AMPUTATION, the cutting off a limb, or other part of the body. See Surgery.

AMPYX, among the ancients, a kind of golden chain which served to bind the hair of the horses on the forehead. The term was afterward used to denote a fillet which formed part of their dress; this was frequently encircled with gold and precious stones.

AMSDORFIANS, a sect of protestants, in the 16th century, who took their name from Amsdorf, their leader. They maintained, that good works were not only unprofitable, but even opposite and pernicious to salvation.

AMULET, a charm or preservative against mischief, witchcraft, or diseases.

Amulets were made of stone, metal, simples, animals, and in a word, of every thing which fancy or caprice suggested; and sometimes they consisted of words, characters, and sentences, ranged in a particular order, and engraved upon wood, &c. and worn about the neck, or some other part of the body.

At other times they were neither written nor engraved, but prepared with many superstitious ceremonies, great regard being usually paid to the influence of the stars. The Arabians have given to this species of amulet the name of talisman.

All nations have been fond of amulets: the Jews were extremely superstitious in the use of them to expel diseases: and the Misna forbids them, unless received from an approved man, who had cured at least three persons before, by the same means.

Even amongst the Christians of the early times, amulets were made of the wood of the cross, or ribands with a text of Scripture written in them, as preservatives against diseases; and therefore the council of Laodicea forbids ecclesiastics to make such amulets, and orders all such as wore them to be cast out of the church.

AMUSETTE, an instrument of war, mounted like a cannon, and fired off like a musket.

AMY, in law, the next friend or relation to be intrusted for an infant.

AMYGLADOIDES *lapis*, in natural history, a fossile body, resembling the kernel of an almond in shape, being the petrified spine of a species of *echinus marinus*, or sea urchin.

AMYGDALUS, the Almond and Peach: a genus of the monogynia order, belonging to the icosandria class of

plants; and in the natural method, ranking under the order pomaceæ. The characters are: the calyx is a single leaved perianthium beneath, tubular, and quinquefid; the corolla consists of five oblong petals, which are inserted into the calyx: the stamina of 30 slender erect filaments, half the length of the corolla, and inserted into the calyx; the antheræ are simple: the pistillum has a round villous germen above; a simple stylus, the length of the stamina; and the stigma headed: the pericarpium is a large roundish villous drupa, with a longitudinal furrow: the seed is an ovate compressed not perforated in the pores. The nut of the almond is covered with a dry skin, that of the peach and nectarine with a soft pulp. The nectarine again is smooth, the peach downy.

There are 7 species with innumerable varieties, the principal of which are:

1. Amygdalus communis, or common almond, a native of Africa, grows to near 20 feet high. The white flowering almond is a variety of this species, and is cultivated for the sake of the flowers and the fruit, though the flowers are inferior to the red.

2. Amygdalus nana, the dwarf almond, is a native of Asia Minor. Of this shrub there are two varieties, the single and the double. Both grow to about four or five feet high, and are in the first esteem as flowering shrubs.

3. Amygdalus Persica, or the Peach, is said to be a native of Europe; but of what place is not known. Cultivation has produced many varieties of this fruit; of which the following are the most esteemed:

1. Admirable. 2. Beautiful Chevreuse. 3. Bellegarde. 4. Bloody Peach. 5. Bourdine. 6. Catharine. 7. Chancellor. 8. Early Purple. 9. Great French Mignon. 10. Late Admirable. 11. Late Purple. 12. Malta. 13. Monstrous Pavy. 14. Montauban. 15. Nivette. 16. Old Newington. 17. Persique. 18. Portugal. 19. Ram bonillet. 20. Red Magdalen. 21. Red Nutmeg. 22. Rossanna. 23. Royal. 24. Small Mignon. 25. Smith's Newington. 26. Venus's Nipple. 27. Vineuse. 28. White Magdalen. 29. White Nutmeg. 30. Yellow Alberge. 31. Noblesse. 32. Double Montagne.

4. Amygdalus nuci Persica, or the Nectarine. Of this many varieties are now cultivated; and the following are some of the most esteemed.

1. Elruge. 2. Golden. 3. Italian. 4. Murrey. 5. Newington. 6. Roman. 7. Scarlet. 8. Temple's. 9. Clermont's. 10. Fairchild's early.

The good kinds of all these species are propagated by budding or inoculation. They will thrive and bear against any wall but one with a north aspect, but the best aspect is south. In the pruning, care must be taken to leave enough of the young bearing wood, and not lay in the branches too close, or to cross each other.

AMYRIS, a genus of the octandria monogynia class and order, and of the natural order of terebintaceæ. The calyx is a small single leaved perianthium, four toothed and persistent: the corolla consists of four oblong petals, concave and expanding: the stamina consist of eight erect subulated filaments: the antheræ are oblong, erect, and the length of the corolla; the pistillum has an ovate germen above; a thickish stylus the length of the stamina; and a four cornered stigma: the pericarpium is a round drupaceous berry: the seed is a globular glossy nut. There are nine species: the most remarkable are:

1. Amyris balsamifera, or rose wood, is found on gravelly hills in Jamaica and others of the West India islands. It rises to a considerable height, and the trunks are remarkable for having large protuberances on them. The leaves are laurel shaped; the small blue flowers are on a branched spike; and the berries are small and black.

2. Amyris elemifera, or shrub which bears the gum elemi, a native of South America. It grows to the height of about six feet.

3. Amyris Gileadensis, or opobalsamum, is an evergreen shrub, growing spontaneously in Arabia Felix, from whence the opobalsam, or balm of Gilead, is procured.

4. Amyris toxifera, or poison wood, is a small tree, with a smooth light coloured bark. From the trunk of this tree distills a liquid as black as ink. Birds feed on the fruit; particularly one called the purple grosbeak, on the mucilage that covers the stone. It grows usually on rocks, in Providence, Ilathera, and others of the Bahama islands.

AMZEL, in ornithology, the name of a bird of the merula or blackbird kind, of which there are two species; the ring amzel or merula torquata, and the merula montana, called simply the amzel. The ring amzel is a little larger than the common blackbird. Its back is of a dusky blackish brown, and its throat and breast are beautifully variegated with spots and streaks of white; and the lower part of the throat is adorned with a fine broad white ring, whence the bird has its name. This ring is of a lunated shape, the points ending at the sides of the neck. The wings and tail are blackish, but in the female variegated with white. This bird feeds on insects and berries, and is common about the peak of Derbyshire, where it is called the Rock Ouzel.

AN JOUR and WASTE, in law, signifies a forfeiture of lands for a year and a day to the king, by persons committing petit treason and felony, and afterward the land falls to the lord.

ANA, among physicians, denotes an equal quantity of the ingredients which immediately precede it in prescriptions: it is written by abbreviation ā or āā; thus, ℞. *thur. myrrh. alum.* āā, i ℈: that is, take frankincense, myrrh, and alum, each a scruple.

ANA, in matters of literature, a Latin termination added to the titles of several books in other languages.

They are collections of the conversation and memorable sayings of men of wit and learning: the Scaligeriana was the first book that appeared with a title in ana, and was afterward followed by the Perroniana, Thuana, Naudæana, Menagiana, and even by Arlequiniana, in ridicule of all books in ana.

ANABAPTISTS, in church history, a sect of protestants, which sprung up in Germany, in 1521, immediately after the rise of Lutheranism. At first, they preached up an entire freedom from all subjection to the civil as well as ecclesiastical power; but the tenet from whence they take their name, and which they still maintain, is their re-baptizing all new converts to their sect, and condemning infant baptism.

Great troubles were occasioned in Germany by this sect; but of all places where they prevailed, none suffered so much by them as the town of Munster. The anabaptists, however, of Holland and Friesland disapproved the seditious behaviour of their brethren of Munster: and

at present, though this sect still subsists as well in Britain as abroad, yet they no longer pretend to be divinely inspired, they no longer oppose magistrates, nor preach up a community of goods, &c.

The anabaptists support their principal doctrine upon those words of our Saviour, "He that believeth, and is baptized, shall be saved." Now, as adults, or grown persons, are alone capable of believing, they argue, that none but adults are fit to be baptized. This doctrine is opposed by alleging the contrary practice of the primitive church, as well as from Scripture, which tells us, that children are capable of the kingdom of heaven, and at the same time assures us, that "except a man be baptized, he cannot enter into the kingdom of God."

ANABATA, a cope or sacerdotal vest, to cover the back and shoulders of the priest.

ANABATHRA, in antiquity, a kind of stones erected by the sides of highways, to assist travellers to mount their horses.

ANABIBAZON, in astronomy, a name given to the northern node of the moon, or dragon's head.

ANABLEPS, in ichthyology, a genus of malacopterygious fishes, with six bones in the branchiostege membrane, and only two small fins at the extremity of the back. Of this genus there is only one known species. It inhabits the sea shore of Surinam.

ANABOLÆUM, or ANABOLE, in antiquity, a kind of great or upper coat, worn over the tunica.

ANABOLEUS, in antiquity, an appellation given to grooms of the stable, or equerries, who assisted their masters in mounting their horses.

As the ancients had no stirrups, or instruments that are now in use for mounting a horse, they either jumped upon his back, or were aided in mounting by anabolei.

ANACALYPTERIA, in antiquity, festivals among the Greeks on the day that the bride was permitted to lay aside her veil, and appear in public. The word is derived from a verb which signifies to uncover.

ANACAMPTERIA, in ecclesiastical antiquity, a kind of little edifices adjacent to the churches, designed for the entertainment of strangers and poor persons.

ANACARDIUM, or CASHEW NUT TREE: a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 12th order, holoraceæ. The characters are: the calyx is divided into five parts, the divisions ovate and deciduous: the corolla consists of five reflected petals, twice the length of the calyx: the stamina consists of ten capillary filaments shorter than the calyx, one of them castrated; the antheræ are small and roundish: the pistillum has a roundish germen; the stylus is subulated, inflected, and the length of the corolla; the stigma oblique: there is no pericarpium; the receptaculum is very large and fleshy: the seed is a large kidney shaped nut, placed above the receptaculum. Only one species is known, *viz.*

Anacardium occidentale. It grows naturally in the West Indies, and arrives at the height of 20 feet in those places of which it is a native. The fruit of this tree is as large as an orange; and is full of an acid juice, which is frequently made use of in making punch. To the apex of this fruit grows a nut, of the size and shape of a hare's kidney, but it is much larger at the end which is next to the fruit than at the other. The shell is very hard; and the kernel, which is sweet and pleasant, is covered with a thin film. Between this and the shell is lodged a thick, blackish, inflammable liquor, of such a caustic nature in the fresh nuts, that if the lips chance to touch it, blisters will immediately follow. The kernels are eaten raw, roasted, or pickled. The caustic liquor just mentioned is esteemed an excellent cosmetic with the West India young ladies, but they must certainly suffer a great deal of pain in its application. The milky juice of this tree will stain linen of a good black, which cannot be washed out. This plant is easily raised from the nuts, which should be planted each in a separate pot filled with light sandy earth, and plunged into a good hot bed of tanner's bark; they must also be kept from moisture till the plants come up, otherwise the nuts are apt to rot. If the nuts are fresh, the plants will come up in about a month; and in two months more they will be four or five inches high, with large leaves: from which quick progress many people have been deceived, imagining they would continue the like quick growth afterward; but with all the care that can be taken, they never come to any kind of perfection even in our best stoves. See Plate Nat. Hist. fig. 14.

ANACHORET, in church history, denotes a hermit, or solitary monk, who retires from the society of mankind into some desert, with a view to avoid the temptations of the world, and to be more at leisure for meditation and prayer.

ANACHORITA, a name given to the cells of recluses; by the ancient canons, no anachorita could be erected without the consent of the bishop.

ANACHRONISM, in matters of literature, an error with respect to chronology, whereby an event is placed earlier than it really happened. Such is that of Virgil, who placed Dido in Africa at the time of Æneas, though in reality she did not come here till 300 years after the taking of Troy.

ANACLASTICS, anaclastica, that part of optics which considers the refraction of light.

ANACLASTIC *glasses*, a low kind of phials, which have the property of being flexible, and emitting a vehement noise, by the application of the human breath. They are made of a fine glass, with flat bellies resembling inverted funnels, with bottoms almost as thin as the skin of an onion. The bottom which is convex, by the action of inspiration will be drawn in with a prodigious crack, and from convex becomes concave; on the contrary, by expiring or breathing gently into them, the bottom returns to its place with the same noise.

ANACLETICUM, among the ancients, a particular blast of the trumpet, by which the fearful and flying soldiers were rallied and recalled to the combat.

ANACREONTIC VERSE, in ancient poetry, a kind of verse, so called from its being much used by the poet Anacreon. It consists of three feet and a half, usually spondees and iambuses, and sometimes anapæsts; such is that of Horace,

Lydia dic per omnes.

ANACYCLUS, a genus of the syngenesia polygamia class and order. The essential character is, recept. chaffy down emarginate: seeds solitary with membranous wings. There are 4 species, all annuals, and somewhat resembling the chrysanthemum in the flower, foliage, and habits.

ANADEMA, in antiquity, denotes the fillet which the kings of Persia wore round their heads. Anadema denotes also a kind of ornament which women wore on their heads like a garland.

ANADIPLOSIS, in rhetoric and poetry, a repetition of the last word of a line, or clause of a sentence, in the beginning of the next: thus,

Pierides, vos hæc facietis maxima Gallo:
Gallo, cujus amor, &c.
Et matutinis accredula vocibus instat,
Vocibus instat, et assiduas jacit ore querelas.

Among physicians, the renewal of a cold fit, in a semitertian fever, before the fit is entirely ended.

ANADROMOUS, among ichthyologists, a name given to all fish which, at stated seasons, go from the fresh waters into the sea, and afterward return back again. Such are the salmon, and some other truttaceous fishes.

ANÆDEIA, in Grecian antiquity, a stool whereon the accused person was placed to make his defence.

ANAGALLIS, in botany, a genus of plants belonging to the pentandria monogynia class and order. The essential character is, corolla rotale; capsule opening horizontally. There are 7 species. The A. arvensis, or common pimpernil, is a beautiful little scarlet flower well known in our fields, and called the poor man's weather glass, from its property of opening in fair weather, and shutting up on the approach of rain. There are some foreign species with larger flowers, cultivated in our gardens; particularly the A. fruticosa, a beautiful flower, figured in Curtis's Magazine, vol. 21. p. 331.

ANAGLYPHICE, the art of embossing.

ANAGNOSTA, or ANAGNOSTES, in antiquity, a kind of literary servant, retained in the families of persons of distinction, whose chief business was to read to them during meals, or at any other time when they were at leisure.

ANAGRAM, a transposition of the letters of some name, whereby a new word is formed, either to the advantage or disadvantage of the person or thing to which the name belongs: thus, from Galenus is formed Angelus; from James, Simea; and so of others. A miserable species of false wit.

ANAGROS, in commerce, a measure for grain used in some cities of Spain, particularly at Seville. Forty-six anagros make about $10\frac{1}{4}$ quarters of London.

ANAGYRIS, BEAN TREFOIL, in botany, a genus of plants with papilionaceous flowers, the vexillum of which is shorter than any of the other petals, and its fruit an oblong pod, containing kidney like seeds; to this is to be added, that three leaves stand on every petal. It belongs to the decandria monogynia class and order of Linnæus. There are three species.

ANALEMMA, in geometry, a projection of the sphere on the plane of the meridian, orthographically made by straight lines and ellipses, the eye being supposed at an infinite distance, and in the east or west points of the horizon.

ANALEMMA denotes likewise an instrument of brass or wood, upon which this kind of projection is drawn, with an horizon and cursor fitted to it, wherein the solstitial colure, and all circles parallel to it, will be concentric circles; all circles oblique to the eye, will be ellipses; and all circles whose planes pass through the eye, will be right lines.

The use of this instrument is to show the common astronomical problems, which it will do, though not very exactly, unless it be very large.

ANALEPTICS, in pharmacy, restorative medicines.

ANALGISTA, among civilians, denotes a tutor who is not obliged to give an account of his conduct.

ANALOGY, in literature, a certain relation and agreement between two or more things, which in other respects are entirely different: thus the foot of a mountain bears an analogy to the foot of an animal, although they are two very different things.

There is likewise an analogy between beings that have some conformity or resemblance to one another: for example, between animals and plants, and between metals and vegetables; but the analogy is still stronger between two different species of certain animals.

Analogy enters much into all our reasoning, and serves to explain and illustrate, but not to demonstrate. Reasoning by analogy, however, may sometimes induce to error: thus, the analogy between the constellation called Leo, and the animal of that name, has given room to some astrologers to imagine that children born under that constellation were inspired with a martial spirit.

ANALOGY, in botany, is a term that has been used to denote the resemblance which plants bear to each other, with regard to their medical properties and uses.

ANALOGY, among geometricians, denotes a similitude of ratios.

ANALYSIS, among logicians, is a method of tracing things backward to their source, and of resolving knowledge into its original principles.

It is also called the method of resolution, and stands opposed to the synthetic method, or method of composition.

The art of this method consists chiefly in combining our perceptions, and classing them together with address; and in contriving a proper expression of our thoughts, so as to represent their several divisions, classes, and relations. This is clearly seen in the manner of computing by figures in arithmetic, but more particularly in the symbols applied in resolving algebraical problems.

ANALYSIS, among mathematicians, the art of discovering the truth or falsehood of a proposition, or its possibility and impossibility. This is done by supposing the proposition, such as it is, true; and examining what follows from thence, until we arrive at some evident truth, or some impossibility, of which the first proposition is a necessary consequence; and from thence establish the truth or impossibility of that proposition.

The analysis of the ancient geometricians consisted in the application of the propositions of Euclid, Apollonius, &c. till they arrived, proceeding step by step, at the truth required. That of the moderns, though not so elegant, must, however, be allowed more ready and general. By this last, geometrical demonstrations are wonderfully abridged, a number of truths are frequently expressed by a single line, and whole sciences may sometimes be learned in a few minutes, which otherwise would be scarcely attained in many years.

Analysis is divided, with regard to its object, into that of finites and infinites.

Analysis of finite quantities, is that which is called specious arithmetic.

Analysis of infinites, is the same with fluxions.

ANALYSIS, in chymistry, the reduction of a mixed body into its principles. This is the chief object of chymistry, and is effected by means of heat and mixture.

ANALYSIS of powers, is the operation of resolving them into their roots, otherwise called evolution. See ALGEBRA.

ANAMORPHOSIS, in perspective and painting, a monstrous projection, or representation of an image on a plane or curve surface, which, beheld at a proper distance, shall appear regular and in proportion. See OPTICS.

ANANAS, the trivial name of a species of the pine apple. See BROMELIA.

ANANCITIS, in antiquity, a kind of figured stone, otherwise called synochitis, celebrated for its magical virtue, of raising the shadows, umbræ, of the infernal gods.

ANAPÆST, anapestus, in ancient poetry, a foot consisting of two short syllables and one long. It is just the reverse of the dactyle.

ANAPHORA, in ancient astronomy, an ascension of the twelve signs of the zodiac from the east, by the daily course of the heavens.

ANAPHORA, in rhetoric, the repetition of the same word or words in the beginning of a sentence or verse: thus Virgil:

Pan etiam Arcadia mecum se judice certet,
Pan etiam Arcadia dicat se judice victum.

ANAPHORA, among ancient physicians, denotes the throwing up of purulent matter by the mouth.

ANAPLASIS, among ancient physicians, the replacing of a fractured bone in the same situation it obtained before it was broken.

ANAPLEROSIS, among surgeons, expresses the restoring deficiencies; and in this sense is the same with prosthesis.

ANAPLEROTICS, in pharmacy, such medicines as promote the growth of flesh in wounds and ulcers.

ANARRHICHAS, the name of a genus of malacopterygious fishes, called by other writers lupus marinus, the sea wolf. See Plate Nat. Hist. fig. 15.

ANAS, in zoology, a genus of birds of the order of anseres, according to Linnæus, the beak of which is convex, with an obtuse point, and the whole verge furnished with transverse lamellose teeth; the tongue is obtuse and ciliated. The nostrils are small and oval; the toes are four in number, three are placed before, one behind, and the middle one is the longest. See Plate Nat. Hist. fig. 16. There are a great many species of this genus, amounting to at least 98, besides many varieties. The most noted species are:

1. Anas Aborea, or black billed whistling duck of Edwards. It is a native of America, and makes a kind of whistling noise.

2. Anas acuta, pin tail, or sea pheasant of Ray. These birds, it is said, are found in great abundance in Connaught in Ireland, in the month of February only; and are much esteemed for their delicacy.

3. Anas Americana, American wigeon, is rather bigger than our wigeon. It inhabits North America, from Carolina to Hudson's Bay; but is no where a common bird.

4. Anas Anser, the goose. Of this species there are several varieties, of which we shall only mention two: the anser ferus, or wild goose, and the anser mansuetus, or tame goose.

5. Anas bernicla is of a brown colour, with the head, neck, and breast, black; and a white collar. These birds, like the bernacles, frequent our coasts in winter; and are particularly plenty, at times, on those of Holland and Ireland, where they are taken in nets placed across the rivers.

6. Anas boschas, common wild duck, or mallard. They abound particularly in Lincolnshire, the great magazine of wild fowls in this kingdom; where prodigious numbers are taken annually in the decoys.

7. Anas Canadensis, is found during the summer in Hudson's Bay, and parts beyond; also in Greenland; and, in the summer months, in various parts of North America, as far as Carolina. This species is now pretty common, in a tame state, both on the continent and in England, where they are thought a great ornament to the pieces of water in many gentlemen's seats.

8. Anas Candida, the snow goose, the general colour of whose plumage is snow white, except the first ten quills, which are black with white shafts; they are very numerous at Hudson's bay; they visit the Severn in May, and stay a fortnight; but go further north to breed.

9. Anas Casarca, or ruddy goose, is found in all the southern parts of Russia and Siberia in plenty. In winter it migrates into India, and returns northward in spring. They have been attempted to be domesticated, by rearing the young under tame ducks; but without success, as they make their escape the first opportunity. The flesh is thought very delicate.

10. Anas Clangula, or golden eye of Ray, is not unfrequent on our sea coast in winter, and appears in small flocks; but passes to the north in spring, in order to breed.

11. Anas Clypeata, or shoveller, of Ray, is sometimes met with in England, though not very commonly. It is said they appear in France in February, and that some of them stay during summer.

12. Anas Creca, or common teal, is frequent in the London markets, along with the wild duck. It is found to the north as high as Iceland.

13. Anas cursor, the race horse or loggerhead goose, inhabits the Falkland Islands, Staaten Land, &c. They are mostly seen in pairs, though sometimes in large flocks. From the shortness of the wings they are unable to fly; but in the water they seem to run, at least they swim, with the assistance of the legs used as oars, at an incredible rate.

14. Anas cygnoides, is the swan goose of Ray, from Guinea, and there is likewise a variety of this species of a less size, called the goose of Muscovy. They are sufficiently common in Britain, and readily mix with the common goose; the breeds uniting as freely, and continuing to produce as certainly, as if no such mixture had taken place.

15. Anas cygnus, or the swan. Of this species there are several varieties, of which we shall only mention two, *viz.* the ferus and the mansuetus.

16. Anas Erythropus, or laughing goose of Edwards, is a native of Europe and America. These visit the fens during winter, in small flocks, and disappear by the middle of March.

17. Anas fabalis, the bean goose, arrives in Lincolnshire in autumn, and retreats to the north of Europe in May. It is called the bean goose, from the likeness of the nail of the bill to a horse bean.

18. Anas ferina, pochard, or red headed wigeon of Ray, frequents the fens in the winter season, and is brought up to the London markets sometimes in considerable numbers, where they are known by the name of Dun Birds, and are esteemed excellent eating.

19. Anas filigula, or tufted duck of Ray, in the winter months is not unfrequent in England; it is common also throughout the Russian empire, going northward to breed.

20. Anas fusca, the brown, or velvet duck, frequents Hudson's bay in summer, where it breeds. It feeds on grass, and retires south in winter; when it is frequently seen as far south as New York. It is now and then seen on the coasts of England.

21. Anas galericulata, or Chinese teal of Edwards.

This most singular and elegant species is a native of China and Japan, where it is kept by the inhabitants for the sake of its beauty. See Plate, Nat. Hist. fig. 17.

22. Anas glacialis, or long tailed duck, breeds in the most northern parts of the world; and only visits our coasts in the severest winters.

23. Anas histrionica, or dusky spotted duck of Edwards, inhabits from Carolina to Greenland. In winter it seeks the open sea, flies high and swiftly, and is very clamorous.

24. Anas magna, the great goose, is of a very large size, weighing near 25 or 30 Russian pounds. It is found in the east of Siberia, from the Lena to Kamtschatka.

25. Anas maula, or scaup duck, is less than the common duck. These birds are said to take their name from feeding on scaup, or broken shell fish. They differ infinitely in colours, so that in a flock of forty or fifty there are not two alike.

26. Anas mersa, or Ural duck of Pallas, is somewhat bigger than the common teal. It is not seen on the ground, as from the situation of its legs it is unable to walk; but it swims very well and quick.

27. Anas minuta, or little white and brown duck of Edwards. This and the former, according to Latham, are found both on the old and new continents.

28. Anas mollissima, or eider duck, is double the size of the common duck. This species is found in the Western Isles of Scotland, and on the Farn Isles; but in greater numbers in Norway, Iceland, and Greenland; whence a vast quantity of the down, known by the name of eider or edder, which these birds furnish, is annually imported. Its remarkably light, elastic, and warm qualities, make it highly esteemed for coverlets. This down is produced from the breast of the birds in the breeding season. It lays its eggs among the stones or plants near the shore; and prepares a soft bed for them, by plucking the down from its own breast. The natives watch the opportunity, and take away both eggs and nest: the duck lays again, and repeats the plucking of its breast: if she is robbed after that, she will still lay; but the drakes must supply the down, as her stock is now exhausted: but if her eggs are taken a third time, she wholly deserts the place.

29. Anas Moschata, or Muscovy duck of Ray, has a naked papillous face, and is a native of India. This species is pretty common in a domesticated state in almost every nation. The male will not unfrequently associate and produce a mongrel breed with the common duck. The name arises from their exhaling a musky odour, which proceeds from the gland placed on the rump in common with other birds.

30. Anas nigra, the black goose, or scoter, is totally black, and has a gibbosity at the base of the bill. It is the lesser black diver of Ray, and measures in length 22 inches. These birds are found on the northern coasts of England and those of Scotland in the winter season; but no where so common as on the French coasts, where they are sometimes seen in prodigious numbers. Their chief food is a glossy bivalve shell, near an inch long, called by the French vaimeaux. See Plate Nat. Hist. fig. 18.

31. Anas querquedula, garganey, or first teal of Aldrovandus. In many places it is called the summer teal.

32. Anas ruficolis, or red breasted goose. This most elegant of geese is found to breed from the mouth of the Ob, along the coasts of the Icy Sea, to that of the Lena.

33. Anas spectabilis, is common in Greenland, where the flesh is accounted excellent. It produces a down as valuable as the eider; and the skins sewed together make very warm garments.

34. Anas sponsa, or summer duck of Catesby, is a most elegant species. It inhabits Mexico, and some of the West India isles, migrating in the summer season as far north as 40 degrees, or a little beyond.

35. Anas strepera, or gad wal, has the wings variegated with black, white, and red. It inhabits England in the winter months, and is also found at the same season in various parts of France and Italy.

36. Anas tadorna, or shieldrake, has a flat bill, a compressed forehead, a greenish black head, and the body is variegated with white. This species is found as far north as Iceland. It breeds in deserted rabbit holes, or occupies them in the absence of the owners, who rather than make an attempt at dislodging the intruders, form others; though, in defect of ready made quarters, these birds will frequently dig holes for themselves. They lay 15 or 16 roundish white eggs. This species, Mr. Latham informs us, may be hatched under a tame duck, and the young readily brought up; but are apt after a few years, to attempt the mastery over the rest of the poultry.

37. Anas tetrax, or campestris, is of the size of a pheasant, and of the nature of the bustard, having no hinder toe. It runs very swiftly, and sits on the ground as the duck does in the water, whence it has its name Anas.

ANASARCA, in medicine, a species of dropsy, wherein the skin appears puffed up and swelled, and yields to the impression of the fingers like dough. See MEDICINE.

ANASTATICA, in botany, the name of a genus of tetradynamious plants of the order siliculosa, called in English, the rose of Jericho: its flower consists of four roundish petals, disposed in the form of a cross; and its fruit is a short biocular pod, containing in each cell a single roundish seed. Two species annual.

ANASTATICA, a species of vorticella, in the fifth order of vermes, infusoria. It is compound, with bell shaped flowers, foot stalks scaly and rigid. This is the second species of clustering polypi described by Trembley.

ANASTOMASIS, or ANASTOMOSIS, in anatomy, the opening of the mouths of vessels, in order to discharge their contained fluids. It likewise denotes the communi-

cation of two vessels at their extremities; for example, the inosculation of a vein with a vein, of an artery with an artery, or of an artery with a vein.

ANASTOMATICS, in pharmacy, medicines supposed to have the power of opening the mouths of vessels, and promoting the circulation of the blood.

ANASTROPHE, in rhetoric and grammar, denotes the inversion of the natural order of the words: such is Saxa per et scopulos, for Per saxa et scopulos.

ANATHEMA, among ecclesiastical writers, imports whatever is set apart, separated, or devoted; but is most usually meant to express the cutting off a person from the privileges of a society and communion with the faithful. The anathema differs from excommunication in the circumstance of being attended with curses and execrations.

Several councils have pronounced anathemas against such as they thought corrupted the purity of the faith.

There are two kinds of anathemas, the one judiciary, and the other abjuratory. The former can only be denounced by a council, a pope, or a bishop; the latter makes a part of the ceremony of abjuration, the convert being obliged to anathematize the heresy he abjures.

ANATHEMA, in heathen antiquity, was an offering or present made to some deity, so called from its being hung up in the temple.

Whenever a person left off his employment, it was usual to dedicate the tools to the patron deity of such a trade. Persons too who had escaped some imminent danger, as shipwreck and the like, or had met with any other remarkable instance of good fortune, seldom failed to testify their gratitude by some present of this kind.

ANATINUS, in conchology, a species of solen, found on the sandy shores of the Indian ocean. It is also a species of the mytillus common in the rivers of England, and known by the name of duck, or small horse muscle.

ANATIS, a species of pediculus insect, that infests the wild duck. It is the name also of another creature that is found in the intestines of the velvet duck: and a species of arcaris, of the order intestina in the vermes class.

ANATOMY is the science which teaches us the internal conformation of the human body, both the solids and fluids of which are its particular objects.

The *solids* of the human body consist of,

1. Bones, which give support to the other parts of the body.
2. Cartilages, which are much softer than the bones, and also flexible and elastic.
3. Ligaments, which are more flexible still, and connect the ends of the bones to each other.
4. Membranes, or planes of minutely interwoven fibres.
5. Cellular substance, which is formed of membranes minutely interwoven with each other.
6. Muscles, which are soft and contractile bundles of fibres.
7. Tendons, which generally form the hard and inelastic terminations of muscles.
8. Viscera, which are portions of the body loosely contained in great cavities.
9. Glands, which separate various fluids from the blood.
10. Vessels, which are membranous canals dividing into branches and transmitting blood and other fluids.
11. Adipose substance, an animal oil contained in the cells of the cellular membrane.
12. The cerebral substance, which is of a peculiar nature.
13. Nerves, which are bundles of white cords connected by one end to the brain or spinal marrow, and thence expanded over every part of the body in order to receive impressions from external objects, or to produce muscular motion.

The *fluids* of the human body are,

1. Blood, which circulates through the vessels and nourishes the whole fabric.
2. Perspirable matter, excreted by the vessels of the skin.
3. Sebaceous matter, by the glands of the skin.
4. Urine, by the kidneys.
5. Ceruminous matter, secreted by the ceruminous glands of the external ear.
6. Tears, by the lachrymal glands.
7. Saliva, by the salival glands of the mouth, &c.
8. Mucus, by the mucous glands of the mouth, &c.
9. Pancreatic juice, by the pancreas.
10. Bile, by the liver.
11. Gastric juice, by the stomach.
12. Oil, by the vessels of the adipose membrane.
13. Synovia, by the synovial glands of the joints.
14. Seminal fluid, by the testes.
15. Milk, by the mammary glands.

Anatomy, therefore, from the names of the parts which it considers, is divided into

1. Osteogeny, which is the doctrine of the growth of the bones.
2. Osteology, or the doctrine of adult bones.
3. Chondrology, or the doctrine of cartilages.
4. Syndesmology, or the doctrine of ligaments.
5. Myology, or the doctrine of muscles.
6. Bursalogy, or the doctrine of the bursæ mucosæ.
7. Splanchnology, or the doctrine of the viscera.
8. Angiology, or the doctrine of the vessels.
9. Adenology, or the doctrine of the glands.
10. Neurology, or the doctrine of the nerves, &c.

OSTEOGENY.

Osteogeny treats of ossification, or the growth of bones. It takes place in the flat bones of the head in the form of radii, which diverge from a common centre. In the middle of the cylindrical bones, it takes place in the form of a flat ring, surrounding the internal, and surrounded by the external periosteum or membranes of the bone. In irregular bones, it commences by a number of minute points.

OSTEOLOGY.

This division of anatomical science treats of the adult or full grown bones.

It is at present taught in the medical schools of London, that bones consist of fibres and lamellæ. The doctrine is nevertheless a false one, for the celebrated Scarpa of Pavia has several years since demonstrated that a cellular, reticular, and vascular parenchyma constitutes the basis in which are secreted the earthy matters, to which bones owe their solidity, and that consequently their intimate structure is the same with that of the soft parts of the body.

The long cylindrical or triangular bones consist of two epiphyses, which form their termination, and are internally spongy, and of a diaphysis, or middle portion, which is placed between the two epiphyses, and is externally of a compact structure, and internally reticular, where its net work supports the bags of the marrow. The broad or flat bones of the body are extremely irregular in their form.

The periosteum of bones is that membrane which covers them, gives attachment to their ligaments, and muscles, and conducts to them vessels and nerves.

The marrow of bones is an oleaginous fluid contained within the membranous bags, occupying their cells; but its use is totally unknown.

Numerous blood vessels pass into bones by small holes on their surface; and the minute manner in which these vessels are distributed is beautifully demonstrated by observing the red tinge which they assume in animals with whose food madder is mixed.

In considering the individual bones of the human body, it is proper to commence with those of the head, which are generally arranged into bones of the skull, and bones of the face. The bones of the skull are eight in number, namely, the os frontis, the two ossa parietalia, the os occipitis, the two ossa temporum, the os sphenoides, and the os ethmoides. The two last of these are said to be common to the head and face, because they constitute a part of both. We shall proceed to consider them in the order in which they are here enumerated.

The os frontis is placed in the fore part of the skull, and forms the brow and the upper part of the orbits of the eyes. It is convex externally, and concave internally, and has a serrated semicircular edge, which is turned upward, while its lower part is extremely irregular. It bears, in form, a great likeness to the shell of the common cockle. In children, and sometimes in women, it is divided down the middle by a longitudinal suture, or serrated junction.

The ossa parietalia form all the superior, and some of the lateral parts of the skull. They are convex externally, concave internally, and of an irregular quadrangular form. Their sides are anterior, posterior, superior, and inferior, which last is of a semicircular form. Their angles are posterior superior, posterior inferior, anterior superior, and anterior inferior; which last is produced into a process.

The os occipitis is situated in the lower and back part of the skull. It is convex externally, concave internally, and irregularly rhomboidal in its form.

The ossa temporum are situated at the lower part of the sides and base of the cranium, and are of a very irregular figure. Their upper part, named os squamosum, is externally smooth, and has a thin semicircular edge; their posterior part, called pars mammillaris, is thicker and less regular; and their inferior part becoming smaller, and extending horizontally inward and forward, obtains the name of os petrosum, from its excessive hardness.

The os sphenoides is situated in the middle of the base of the skull, and extends across it from one temple to the other. It is extremely irregular in its figure, and is divided into a body placed in the middle, two alæ on the sides, and two pterygoid processes projecting downward from the junction of the body and alæ.

The os ethmoides is placed in the middle of the fore part of the basis of the cranium. It consists of a cribriform portion, which is placed horizontally; a nasal portion, which, passing downward, contributes to separate the nares; two ossa turbinata, which are external to the last; the cells of the bone, which are placed still more externally; and the ossa plana, which are most external, and assist in the formation of the inner sides of the orbits.

These bones of the cranium are connected by certain sutures or serrated junctions: which are, the coronal, ascending over the fore part of the skull; the lambdoidal, placed at its posterior part; the sagittal, joining these two in the middle of the upper part of the skull; the squamous, which are placed on each side; and the sphenoidal and ethmoidal, surrounding the bones of the same name.

The bones of the face are fourteen in number; and of these

The ossa nasi constitute the arch of the nose.

The ossa lachrymalia are placed at the fore part of the inner edge of the orbits of the eyes.

The ossa malarum, of an irregular square form, constitute the prominencies of the cheeks.

The ossa maxillaria superiora are of a very irregular form, constitute the upper jaw, and contain the sixteen upper teeth.

The ossa palati are also very irregular, and situated at the posterior part of the palate, nares and orbit.

The ossa turbinata inferiora very much resemble those of the ethmoid bone.

The vomer is a thin plate of bone, which contributes to complete the septum narium, or division of the nares.

The maxilla inferior is, as its name indicates, the bone of the lower jaw, and contains the inferior sixteen teeth.

The teeth are thirty-two in number, internally composed of a bony substance, harder in its texture than common bone, and covered at their greater extremity with a cortex or enamel, which is much harder still. Externally each tooth consists of a head, a neck, or narrow place immediately below the head, and one or more fangs or roots, which are sunk in the jaws. They consist of three classes, *viz.* four incisores, the front teeth of each jaw; two cuspidati, placed on each side of the former: four bicuspides behind the last; and six molares behind these. The last of the molares, from the lateness of the period at which it makes its appearance, is termed dens sapientiæ.

The os hyoides, or bone of the tongue, resembles in form the Greek υ, whence its name. It consists of a body, two cornua, and two appendices.

The bones of the trunk consist of those of the spine, the pelvis, and the thorax.

The spine consists of twenty-four true or moveable, and five false or immoveable vertebræ, likewise denominated the os sacrum, and of one small bone named os coccygis. The true vertebræ consist of a body, a ring placed behind the body transmitting the spinal marrow, and of seven processes, four of which are articular, or serve to connect the vertebræ with each other; and three are for the purposes of muscular attachment: of these two are termed transverse, from their projecting laterally; and one spinous, from its forming the ridge or spine of the back. The true vertebræ are also divided into classes, from their situation in the cer-

vix or neck, in the dorsum, or back, and in the lumbar regions or loins. The first class is the cervical, including the first seven; the first of which is termed atlas, from its supporting the head; and the second dentatus, from its having a tooth like process, which passes upward into the former, and all of which have their transverse processes perforated by a hole for transmitting the vertebral arteries to the head. The second class is the dorsal, consisting of twelve, which are larger than the cervical, and are distinguished by having their sides and transverse processes depressed for connection with the ribs. The third class is the lumbar, consisting of five, which are larger than any of the superior ones. The os sacrum resembles a pyramid reversed, somewhat concave internally and convex externally. It constitutes the posterior part of the pelvis, and in the young animal consists of five different portions, resembling considerably the true vertebræ, whence its name of false vertebræ. The os coccygis, in form, very much resembles the os sacrum, of which it is merely an appendix fixed to its lower part.

The pelvis, or inferior cavity of the trunk, in addition to the two bones last mentioned, consists of the two ossa innominata. These, in the young subject, are formed of three distinct bones, *viz.* the ossa ilium or haunch bones, which are placed at their upper part, the ossa pubis or share bones, which compose their fore part, and the ossa ischium which constitute their inferior part.

The thorax, or superior cavity of the trunk, in addition to the vertebræ, is formed anteriorly by a long narrow bone, named sternum, and laterally as well as in some measure anteriorly and posteriorly by the twenty-four ribs, which are long, narrow, and curved bones, attached by their heads or posterior ends to the vertebræ, and by their anterior cartilages either to the sternum or each other. The upper seven, from their being attached in the former way, are named true ribs; the inferior five are termed false.

The bones of the upper extremities are generally divided into those of the shoulder, arm, fore arm, and hand.

The shoulder consists of two bones, *viz.* the clavicula and the scapula. The clavicula or collar bone, is situated between the top of the sternum or breast bone and the extremity of the shoulder, and sometimes resembles in form an italic *f*. The scapula is a triangular flat bone which forms the greatest part of the shoulder. It is in some measure situated behind the upper part of the thorax. Its superior and inferior sides are denominated costæ; its posterior side is called its base.

The arm has only one bone, termed the os humeri, the upper part of which forms a round head, which is received by the scapula, and its lower part terminates in two condyles, giving attachment to muscles, and a trochlea or pulley between them, for articulation with the following bones:

The fore arm consists of two bones, *viz.* the radius and ulna, the latter of which is placed on the inside of the fore arm, and chiefly allows of flexion and extension, while at the same time it serves as an axis to the radius, which so revolves around it as to effect that which is called the supination and pronation of the hand.

The bones of the hand are divided into those of the carpus, metacarpus, fingers and thumb. The carpus consists of eight small irregular bones, named schaphoides, lunare, cuneiforme, and piziforme, which form the first row; and trapezium, trapezoides, magnum, and unciforme, which form the second. The metacarpus consists of four bones, having broad bases attached to the carpus, and round heads for articulation with the fingers. Each of the fingers, as well as the thumb, consists of three bones; all of which, except the terminating ones, possess a head and base tipped with cartilage for articulation with its fellows.

The bones of the lower extremities consist of those of the thigh, leg, and foot.

The thigh has only one bone, termed os femoris, the upper part of which forms a round head, received by a cup like cavity, called acetabulum, of the os innominatum. Below this is the neck of the bone, and at its base two protuberances called trochanters, into which are fixed the muscles which rotate the thigh. The back of the bone is marked by a rough line which divides into two at its lower part, and terminates in the condyles of the bone; which inferiorly are joined to the tibia, a bone of the leg, and laterally give attachment to various muscles.

The bones of the leg are three in number, *viz.* the patella or knee pan, a small round bone requiring no particular description; the tibia, which is superiorly large, has a triangular body, and terminates inferiorly in the malleolus internus, or inner ankle; and the fibula, a long triangular bone, placed on the outside of the leg, articulated above to the tibia, and below terminating in the malleolus externus, or outer ankle.

The bones of the foot are divided into those of the tarsus, metatarsus, and toes. The tarsus consists of seven bones, named astragalus, os calcis, naviculare, cuboides, cuneiforme externum, medium, and internum. The metatarsus is composed of five bones, having broad bases and round heads. The phalanges of the toes are three in number; each of their bones are shorter than those of the finger, and the great toe possesses only two.

CHONDROLOGY.

Under this head it is only necessary to state that, in the recent subject, all the articular surfaces of bones are covered by cartilage. Interarticular cartilages are also placed in some of them, as in the joint of the lower jaw, of the clavicle and sternum, of the knee, &c.

SYNDESMOLOGY.

Capsular ligaments surround all the joints, but those which possess the hinge like motion have also lateral ligaments to render them firm, and to prevent their moving from side to side, while those possessing motion in every direction have generally ligaments internal to the capsular, as the round ligament of the hip joint, the beginning of the bicipital tendon in the shoulder, the perpendicular ligament of the processus dentatus, &c.

BURSALOGY.

The mucous bags, called bursæ mucosæ, are placed wherever tendons pass over each other, or over any solid part, and serve the purpose of lubricating these tendons.

MYOLOGY.

Of the muscles of the teguments of the cranium.

The skin that covers the cranium is moved by a single broad digastric muscle, and one small pair.

1. The occipito frontalis arises from the transverse protuberant ridge of the os occipitis; thence it comes straight forward by a broad thin tendon, which covers the upper part of the cranium at each side; when it comes as far forward as the hair of the front, it becomes fleshy, and descends to be inserted into the orbicularis palpebrarum of each side. Its use is to pull the skin of the head backward.

2. The corrugator supercilii arises from the internal angular process of the os frontis, and is inserted into the inner and inferior fleshy part of the occipito frontalis muscle. Its use is to draw the eyebrow of that side toward the other.

Of the muscles of the ear.

The muscles of the ear may be divided into three classes, *viz.* the common, proper, and internal. The common move the whole ear, the proper only affect the particular parts of it to which they are connected, and the internal the small bones within the tympanum.

The common muscles are,

1. The attollens aurem arises from the tendon of the occipito frontalis, and is inserted into the upper part of the ear, opposite to the antihelix. Its use is to draw the ear upward.

2. The anterior auris arise near the posterior part of the zygoma, and is inserted into a small eminence on the back of the helix. Its use is to draw this eminence a little forward and upward.

3. The retrahentes auris arise from the root of the mastoid process, and are inserted into that part of the back of the ear which is opposite to the septum conchæ. Their use is to draw the ear back.

The proper muscles are,

1. The helicis major arises from the acute process of the helix, and is inserted a little above. Its use is to depress that part from which it arises.

2. The helicis minor arises from the inferior and anterior part of the helix, and is inserted into the crus of the helix near its fissure. Its use is to contract the fissure.

3. The tragicus arises from the root of the tragus, and is inserted into the point of the tragus. Its use is to pull the point of the tragus a little forward.

4. The antitragicus arises from the internal part of the antitragus, and is inserted into the tip of the antitragus. Its use is to turn the tip of the antitragus outward.

5. The transversus auris arises from the prominent part of the concha on the dorsum of the ear; and is inserted opposite into the contiguous part of the antihelix. Its use is to draw the parts to which it is connected toward each other.

The muscles of the internal ear are three:

1. The laxator tympani arises from the spinous process of the sphenoid bone, and passes through the fissura glasseri to be inserted into the long process of the malleus. Its use is to draw the malleus obliquely forward.

2. The tensor tympani arises from the cartilaginous extremity of the eustachian tube, and spinous process of the sphenoid bone, from thence running backward through its osseous semicanal, it is inserted into the posterior part of the handle of the malleus. Its use is to pull the malleus and membrana tympani inward.

3. The stapedius arises from a little cavern in the posterior part of the tympanum, and is inserted into the posterior part of the head of the stapes. Its use is to draw the stapes obliquely upward.

Of the muscles of the eye lids.

The palpebræ, or eyelids, have one muscle common to both, and the upper eyelid one proper to itself.

1. The orbicularis palpebrarum arises from the outer edge of the orbitar process of the superior maxillary bone, and from a tendon near the inner angle of the eye; then surrounding the eye, and covering the eyelids, it is inserted into the nasal process of the superior maxillary bone. Its use is to shut the eye.

2. The levator palpebræ superioris arises from the upper part of the foramen opticum, and is inserted into the tarsus of the upper eyelid. Its use is to open the eye.

Muscles of the eye ball.

The muscles which move the globe of the eye are six, *viz.* four straight and two oblique.

The four straight muscles very much resemble each other, and arise from the bottom of the orbit around the foramen opticum of the sphenoid bone. They are inserted at the fore part of the globe of the eye into the anterior part of the tunica selerotica, and under the tunica adnata, at opposite sides, which indicates both their names and use; so that they scarcely require any further description, but to name them singly. They are the levator oculi, depressor oculi, adductor oculi, and abductor oculi.

The oblique muscles are two:

1. The obliquus superior, or trochlearis, arises from the edge of the foramen opticum at the bottom of the orbit, between the levator and adductor; hence it runs through a cartilaginous trochlea on the inside of the internal angular process of the os frontis, and is inserted into the tunica sclerotica, between the attollens and optic nerve. Its use is to roll the globe of the eye, and to turn the pupil downward and outward.

2. The obliquus inferior arises from the outer edge of the orbitar process of the superior maxillary bone, and is inserted into the selerotica, between the abductor and optic nerve. Its use is to oppose the superior.

Of the muscle of the nose.

There is only one muscle on each side that can be called proper to the nose, though it is affected by several muscles of the face.

The compressor naris arises from the root of the ala nasi externally, and is inserted slightly into the anterior extremity of the os nasi. Its use is to compress the ala toward the septum nasi.

Muscles of the mouth and lips.

The mouth has nine pair of muscles, which are inserted into the lips, and a common one formed by the termination of these, *viz.* three above, three below, three outward, and the common muscle surrounding the mouth.

The three above are,

1. The levator anguli oris arises from a hollow of the superior maxillary bone, and is inserted into the angle of the mouth. Its use is to draw the corner of the mouth upward.

2. The levator labii superioris alæque nasi arises by two origins; the first from the external part of the orbitar

process of the superior maxillary bone. The first and shortest portion is inserted into the upper lip and orbicularis labiorum; the second and longest into the upper lip and outer part of the ala nasi. Its use is to raise the upper lip and ala nasi toward the orbit, and a little outward.

3. The depressor labii superioris alæque nasi arises anteriorly from the os maxillare superius, and is inserted into the upper lip and root of the ala nasi. Its use is to draw the upper lip and ala nasi downward and backward.

The three below are,

1. The depressor anguli oris arises from the lower edge of the maxilla inferior, and is inserted into the angle of the mouth. Its use is to pull down the corner of the mouth.

2. The depressor labii inferioris arises from the inferior part of the lower jaw, and is inserted into the edge of the under lip. Its use is to pull the under lip and skin of the chin downward and outward.

3. The levator labii inferioris arises anteriorly from the lower jaw, and is inserted into the under lip and skin of the chin. Its use is to pull the parts into which it is inserted upward.

The three outward are,

1. The buccinator arises from the lower jaw, as far back as the last dens molaris and root of the coronoid process; from the upper jaw, between the last dens molaris and pterygoid process of the sphenoid bone; and is inserted into the angle of the mouth. Its use is to draw the angle of the mouth backward, and to contract its cavity.

2. The zygomaticus major arises from the os malæ, near the zygomatic suture, and is inserted into the angle of the mouth. Its use is to draw the corner of the mouth upward and outward.

3. The zygomaticus minor arises above the origin of the former, and is inserted near the corner of the mouth. Its use is to draw the corner of the mouth outward and upward.

The common muscle is,

The orbicularis oris. This muscle is, in a great measure, formed by the muscles that move the lips, and surrounds the mouth like a sphincter. Its use is to shut the mouth.

Muscles of the lower jaw.

The lower jaw has four pair of muscles for its elevation or lateral motions, *viz.* two which are seen on the side of the face, and two concealed by the angle of the jaw.

1. The temporalis arises from a semicircular ridge of the parietal bone, and from all the temporal fossa of the cranium, and is inserted into the coronoid process of the lower jaw. Its use is to pull the lower jaw upward.

2. The masseter arises from the inferior and interior part of the zygoma, and is inserted into the outside of the angle of the lower jaw. Its use is to pull the lower to the upper jaw.

3. The pterygoideus internus arises from the pterygoid fossa, and is inserted into the angle of the lower jaw internally. Its use is to draw the jaw upward and toward the opposite side.

4. The pterygoideus externus arises chiefly from the outer side of the external pterygoid process, and is inserted into the fore part of the condyloid process. Its use is to pull the lower jaw forward and to the opposite side.

The muscles which appear about the anterior part of the neck.

On the side of the neck are two muscles or layers:

1. The musculus cutaneus vulgo platysma myoides arises from the cellular substance that covers the upper parts of the deltoid and pectoral muscles, and is inserted into the integuments covering the side of the lower jaw. Its use is to corrugate the integuments to which it is attached.

2. The sterno cleido mastoideus arises by two distinct origins; the anterior from the top of the sternum; the posterior from the upper and anterior part of the clavicle; both unite to be inserted into the mastoid process. Its use is to turn the head to one side, and bend it forward.

Muscles situated between the lower jaw and os hyoides.

There are four layers before and two muscles at the side. The four layers are,

1. The digastricus arises from the fossa at the root of the mastoid process of the temporal bone, becomes tendinous, runs through the stylo hyoides, is fixed by a ligament to the os hyoides, and then runs forward and is inserted into a roughness at the inferior edge of the chin. Its use is to open the mouth, or to elevate the larynx, &c.

2. The mylo hyoideus arises from all the inside of the lower jaw, and is inserted into the basis of the os hyoides. Its use is to pull the os hyoides forward, upward, and laterally.

3. The genio hyoideus arises from the middle of the lower jaw internally, and is inserted into the basis of the os hyoides. Its use is to draw this bone forward to the chin.

4. The genio hyo glossus arises from the inside of the middle of the lower jaw, and is inserted into all the length of the tongue, and base of the os hyoides. Its use is, according to the direction of its fibres, to depress the tongue, or to draw the os hyoides forward.

The two muscles at the side are,

1. The hyo glossus arises from the base, cornu, and appendix of the os hyoides, and is inserted into the side of the tongue. Its use is to pull the tongue inward and downward.

2. The lingualis arises from the root of the tongue laterally, and is inserted into the tip of the tongue. Its use is to contract the substance of the tongue.

Muscles situated between the os hyoides and trunk.

These may be divided into two layers. The first layer consists of two muscles:

1. The sterno hyodeus arises, thin and fleshy, from about the cartilaginous extremity of the first rib, and is inserted into the base of the os hyoides. Its use is to pull the os hyoides downward.

2. The omo hyoideus arises from the superior costa of the scapula, near the semilunar notch, and is inserted into the base of the os hyoides. Its use is to pull the os hyoides obliquely downward.

The second layer consists of three muscles:

1. The sterno thyroideus arises from the inner edge of the uppermost bone of the sternum, and is inserted into the rough line at the inferior edge of the thyroid cartilage. Its use is to draw the larynx downward.

2. Thyreo hyoideus arises from the rough line opposite to the former, and is inserted into part of the basis, and almost all the cornu of the os hyoides. Its use is to pull the os hyoides downward, or the thyroid cartilage upward.

3. The crico thyroideus arises from the side and fore part of the cricoid cartilage, and is inserted by two portions; the first into the lower part of the thyroid cartilage; the second into its inferior cornu. Its use is to pull forward and depress the thyroid, or to elevate and draw backward the cricoid cartilage.

Muscles situated between the lower jaw and os hyoides laterally.

They are five in number. Three proceed from the styloid process of the temporal bone, from which they have half of their names; and two from the pterygoid process of the sphenoid bone.

The three from the styloid process are,

1. The stylo glossus arises chiefly from the styloid process, and is inserted into the root, side and tip of the tongue. Its use is to draw the tongue laterally and backward.

2. The stylo hyoideus arises from the inferior part of the styloid process, and is inserted into the os hyoides between its base and cornu. Its use is to pull the os hyoides to one side and a little upward.

3. The stylo pharyngeus arises from the root of the styloid process, and is inserted into the side of the pharynx and back of the thyroid cartilage.

The two from the pterygoid process are,

1. The circumflexus, or tensor palati, arises chiefly from the spinous process of the sphenoid bone, then runs over the hook of the internal pterygoid process, and spreads into a broad membrane, which is inserted into the velum pendulum palati. Its use is to stretch the velum.

2. The levator palati arises chiefly from the extremity of the pars petrosa of the temporal bone, and is inserted into the velum pendulum palati. Its use is to draw the velum upward and backward.

Muscles situated about the entry to the fauces.

There are two on each side, and a single one in the middle.

The two on each side are,

1. The constrictor isthmi faucium arises from the side of the tongue; thence running upward before the amygdala, it is inserted into the middle of the velum pendulum palati. Its use is to draw the velum toward the root of the tongue.

2. The palato pharyngeus arises chiefly from the middle of the velum pendulum palati; thence passing within the posterior arch behind the amygdala, it is inserted into the edge of the upper and back part of the thyroid cartilage. Its use is to draw the uvula and velum downward and backward.

The one in the middle is,

The azygos uvulæ arises from the extremity of the suture, which joins the palate bones, and is inserted into the tip of the uvula. Its use is to raise the uvula upward and forward.

Muscles situated on the posterior part of the pharynx.

Of these there are three pair.

1. The constrictor pharyngis inferior arises from the side of the thyroid, and from the cricoid cartilage, and is inserted into the white line on the middle of the pharynx. Its use is to compress that part of the pharynx which it covers.

2. The constrictor pharyngis medius arises chiefly from the appendix and cornu of the os hyoides, and is inserted into the middle of the cuneiform process of the os occipitis, and is joined to its fellow at a white line in the middle back part of the pharynx. Its use is to compress that part of the pharynx which it covers.

3. The constrictor pharyngis superior arises above from the cuneiform process of the os occipitis lower down, from the pterygoid process of the sphenoid bone, and from the upper and under jaw, near the last dentes molares. It is inserted into a white line in the middle of the pharynx. Its use is to compress the upper part of the pharynx.

Muscles situated about the glottis.

They consist generally of four pair of small muscles, and a single one.

1. The crico arytænoideus posticus arises in the back part of the cricoid cartilage, and is inserted into the posterior part of the base of the arytenoid cartilage. Its use is to open the rima glottidis.

2. The crico arytænoideus lateralis arises from the cricoid cartilage laterally, and is inserted into the side of the base of the arytenoid cartilage. Its use is to open the rima glottidis.

3. The thyreo arytænoideus arises from the under and back part of the middle of the thyroid cartilage, and is inserted into the arytenoid cartilage, higher up than the crico arytænoidens lateralis. Its use is to pull the arytenoid cartilage forward.

4. The arytænoideus obliquus arises from the base of one arytenoid cartilage, and crossing its fellow, is inserted near the tip of the other. When both act, they pull the arytenoid cartilages toward each other.

The single muscle is,

The arytænoideus transversus arises from the side of one arytenoid cartilage, and is inserted in the same manner into the other. Its use is to shut the rima glottidis.

Besides these there are a few disgregated muscular fibres on each side, which, from their general direction, are named the thyreo epiglottidei, and arytæno epiglottidei.

Muscles situated in the fore part of the abdomen.

These consist of three broad layers on each side; always a long one, and generally also a short one, on each side the linea alba.

The three layers are,

1. The obliquus descendens externus arises by eight heads from the lower edges of an equal number of inferior ribs at a little distance from their cartilages, and is inserted into the whole length of the linea alba, and into the anterior extremity of the os ilium. Its use is to support and compress the abdomen, and to bend the loins.

2. The obliquus ascendens internus arises from all the spine of the ilium, from the os sacrum, the three undermost lumbar vertebræ, and from Poupart's ligament. It is inserted into the cartilago ensiformis, and into the cartilages of the seventh and those of all the false ribs. Its use is to assist the former, but to bend the trunk in an opposite direction.

3. The transversalis arises from the inner part of the cartilages of the seven lower ribs, from the spine of the os ilium internally, and from the tendon of the external oblique muscle. It is inserted into the cartilago ensiformis, and into the whole length of the linea alba. Its use is to compress the abdominal viscera.

The long muscle in the middle is

The rectus abdominis, which arises from the symphysis pubis, and is inserted into the cartilages of the three inferior true ribs. Its use is to compress the fore part of the belly, and to bend the loins.

The short muscle in the middle is the pyramidalis arising along with the rectus, and inserted into the linea alba, half way between the os pubis and umbilicus. Its use seems to be to assist the rectus.

Muscles about the male organs of generation.

Each of the testes has one muscle.

The cremaster arises from the lower part of the internal oblique, and after having pierced the ring of the external, descends upon the spermatic chord, and is inserted into the tunica vaginalis of the testis. Its use is to elevate that gland.

The penis has three pair of muscles.

1. The erector penis arises from the tuberosity of the ischium, and is inserted into the membrane covering the corpora cavernosa penis. Its use is to compress the crus penis.

2. The accelerator urinæ, or ejaculator seminis, arises from the sphincter ani and membranous part of the urethra, and from the crus penis. It is inserted into a line in the middle of the bulb. Its use is to drive the urine or semen forward.

3. Transversus perinei arises from the tough fatty membrane covering the tuberosity of the ischium, and is chiefly inserted into the accelerator urinæ. Its use is to dilate the bulb.

There is often a fourth muscle named

4. Transversus perinei alter, which arises behind the former, runs more forward, and is inserted into the fore part of the accelerator urinæ. Its use is to assist the former.

Muscles of the anus.

The anus has a single muscle, and one pair. The single muscle is

The sphincter ani, which arises from the skin and fat surrounding the verge of the anus, and is inserted, before, into the perineum, acceleratores urinæ, and transversi perinei; behind, into the extremity of the os coccygis. Its use is to close the anus.

The levator ani arises extensively within the pelvis, and is inserted into the sphincter ani, &c. Its chief use is to draw the rectum upward.

Muscles of the female organs of generation.

The clitoris has one pair.

The erector clitoridis arises internally from the crus of the ischium, and is inserted into the crus and body of the clitoris. Its use is to draw the clitoris downward and backward.

The vagina has one pair.

The sphincter vaginæ arises from the sphincter ani, and from the back of the vagina, and is inserted into the crus and body of the clitoris. Its use is to contract the mouth of the vagina.

The transversus perinei, sphincter ani, and levator ani, in the female, almost precisely resemble the same muscles in the male.

Muscles situated within the pelvis.

Of these there are two pairs.

1. Obturator internus arises from the internal circumference of the thyroid foramen, and is inserted into the top of the trochanter major. Its use is to roll the os femoris obliquely outward.

2. The coccygeus arises from the spinous process of the os ischium, and is inserted into the end of the sacrum, and into the os coccygis. Its use is to move the os coccygis forward.

Muscles situated within the cavity of the abdomen.

They consist of a single muscle and four pairs.

The diaphragm is a broad thin muscle forming a septum between the thorax and abdomen, concave below and convex above. It is commonly divided into two portions.

1. The superior or greater muscle of the diaphragm arises from the cartilago ensiformis, from the cartilages of the seventh and all the inferior ribs, and is inserted into a tendon situated in the middle of the septum.

2. The inferior or lesser muscle of the diaphragm arises from the second, third, and fourth lumbar vertebræ, by eight heads; of which two in the middle, called its crura, are the longest: and is inserted into the posterior part of the middle tendon. Its chief use is as a principal agent in respiration.

The four pairs are,

1. The quadratus lumborum arises from the posterior part of the spine of the ilium, and is inserted into the transverse processes of the lumbar vertebræ, into the last rib, and into the last dorsal vertebra. Its use is to move the loins to one side.

2. Psoas parvus arises from the sides of the two upper lumbar vertebræ, and is inserted into the brim of the pelvis. Its use is to assist the psoas magnus in bending the loins.

3. Psoas magnus arises from the side of the body and transverse process of the last dorsal vertebra, and in the same manner from all the lumbar. It is inserted into the trochanter minor. Its use is to bend the thigh.

4. The iliacus internus arises from the transverse process of the last vertebra of the loins, from the crista, and from the hollow part of the ilium. It is inserted along with the former. Its use is to assist the psoas.

Muscles on the fore part of the thorax.

These consist of two layers, and the first layer of one muscle.

The pectoralis major arises from the extremities of the fifth and sixth ribs, from almost all the sternum, and from half the anterior part of the clavicle. It is inserted into the outside of the groove of the biceps. Its use is to move the arm forward and upward.

The second layer consists of three muscles.

1. The subclavius arises from the cartilage of the first rib, and is inserted into the inferior part of the clavicle. Its use is to pull the clavicle downward and forward.

2. The pectoralis minor arises from the upper edge of the third, fourth, and fifth ribs, near their cartilages, and is inserted into the coracoid process of the scapula. Its use is to bring the scapula forward and downward.

3. The serratus magnus arises from the nine superior ribs, and is inserted into the whole base of the scapula internally. Its use is to move that bone forward.

Muscles placed between the ribs.

These are the intercostales externi et interni, which, arising in two layers from the lower edge of one rib, are inserted into the upper edge of another, and whose use is to approximate the ribs.

The muscles within the thorax are one pair.

The triangularis, or sterno costalis, arises from the cartilago ensiformis laterally, and from the inferior part of the edge of the middle bone of the sternum. It is inserted into the lower edge of the cartilages of the third, fourth, and fifth ribs. Its use is to depress these cartilages.

Muscles on the fore part of the neck, close to the vertebræ.

They consist of one layer, formed by four muscles.

1. Longus colli arises from the three superior dorsal vertebræ laterally, and from the transverse process of the third, fourth, fifth, and sixth cervical. It is inserted into the fore part of the vertebræ of the neck. Its use is to bend the neck.

2. The rectus capitis internus major arises from the transverse processes of the third, fourth, fifth, and sixth cervical vertebræ, and is inserted into the cuneiform process of the os occipitis. Its use is to bend the head forward.

3. Rectus capitis internus major arises from the body of the atlas, and is inserted into the condyloid process of the os occipitis. Its use is to nod the head forward.

4. The rectus capitis lateralis arises from the tip of the transverse process of the atlas, and is inserted into the os occipitis external to the foramen magnum. Its use is to bend the head to one side.

On the side of the neck,

1. Scalenus anticus arises from the fourth, fifth, and sixth transverse processes of the neck, and is inserted into the upper side of the first rib.

2. Scalenus medius arises from the transverse processes of the cervical vertebræ, and is inserted into the first rib.

3. Scalenus posticus arises from the fifth and sixth transverse processes of the cervical vertebræ, and is inserted into the upper edge of the second rib. The use of the three scaleni is to bend the neck to one side, or to elevate the ribs and dilate the thorax.

Muscles situated on the back of the trunk.

The following muscles are described as they appear on dissection.

1. The trapezius, seu cucularis, arises from the protuberance of the os occipitis, and from the rough line that extends from it toward the temporal bone, runs down along the nape of the neck, where it seems to arise from its fellow; arises also from the spinous processes of the two inferior cervical, and from those of all the dorsal vertebræ. It is inserted into the posterior half of the clavicle, into the acromion, and into almost all the spine of the scapula. Its use is to move the scapula according to the three different directions of its fibres.

2. The latissimus dorsi arises from the back of the spine of the ilium, from all the spinous processes of the sacrum and lumbar vertebræ, and from the seven inferior ones of the vertebræ of the back: also from the extremities of the three or four inferior ribs. It is inserted into the inner edge of the groove of the tendon of the biceps. Its use is to pull the arm backward and downward, and to roll the os humeri.

3. The serratus posticus inferior arises from the spinal processes of the two inferior dorsal vertebræ, and from the three superior lumbar. It is inserted into the lower edges of the four inferior ribs. Its use is to depress the ribs into which it is inserted.

4. The rhomboideus is divided into two portions. 1. The rhomboideus major, which arises from the spinous processes of the five superior vertebræ of the back, and is inserted into all the basis of the scapula below its spine. Its use is to draw the scapula obliquely upward and directly inward. 2. Rhomboideus minor, which arises from the spinous processes of the three inferior vertebræ of the neck, and from the ligamentum nuchæ. It is inserted into the base of the scapula, opposite to its spine. Its use is to assist the former.

5. The serratus superior posticus, arises from the spinous processes of the three last vertebræ of the neck, and the two uppermost of the back. It is inserted into the second, third, fourth, and fifth ribs. Its use is to elevate the ribs and dilate the thorax.

6. The levator scapulæ arises from the transverse processes of the five superior vertebræ of the neck. It is inserted fleshy into the superior angle of the scapula. Its use is to pull the scapula upward and forward.

On the neck,

1. The splenius arises from the four superior spinous processes of the vertebræ of the back, from the five inferior of the neck, and adheres to the ligamentum nuchæ. It is inserted into the five superior transverse processes of the cervical vertebræ, into the back of the mastoid process, and into the os occipitis. Its use is to bring the head backward laterally.

2. The complexus arises from the transverse processes of the seven superior vertebræ of the back, and four inferior of the neck; it also receives a slip from the spinous process of the first vertebra of the back. It is inserted into the protuberance of the os occipitis, and into part of its transverse ridge. Its use is to draw the head backward laterally.

3. The trachelo mastoideus arises from the transverse processes of the three uppermost dorsal and five lowermost cervical vertebræ. It is inserted into the back of the mastoid process. Its use is to assist the complexus.

4. The transversalis colli arises from the transverse processes of the five uppermost vertebræ of the back. It is inserted into the transverse processes of all the cervical vertebræ, except the first and the last. Its use is to turn the neck obliquely backward and to one side.

5. The rectus capitis posticus major arises from the spinous process of the dentata. It is inserted into the os occipitis. Its use is to pull the head backward.

6. The rectus capitis posticus minor arises from the back part of the atlas. It is inserted behind the foramen magnum. Its use is to assist the rectus major.

7. The obliquus capitis superior arises from the transverse process of the atlas. It is inserted into the os occipitis, behind the back of the mastoid process. Its use is to draw the head backward.

8. The obliquus capitis inferior arises from the spinous process of the dentata, and is inserted into the transverse process of the atlas. Its use is to rotate the head.

On the back near to the spine:

1. The sacro lumbalis arises in common with the longissimus dorsi, inserted into the curve of all the ribs. Its use is to pull the ribs down, and assist to erect the trunk of the body.

2. The longissimus dorsi arises from the side, and all the spines of the sacrum; from the posterior spine of the ilium, from the spines, and from the transverse processes of the lumbar vertebræ. It is inserted into the transverse processes of the dorsal vertebræ, and into the lower edge of all the ribs except the two inferior, near their tubercles. Its use is to extend the trunk.

3. The spinalis dorsi arises from the spines of the two uppermost lumbar vertebræ, and the three inferior dorsal vertebræ. It is inserted into the spines of the nine uppermost dorsal vertebræ, except the first. Its use is to fix the vertebræ, and to assist in raising the spine.

4. The semispinalis dorsi arises from the transverse processes of the seventh, eighth, ninth, and tenth dorsal vertebræ, and is inserted into the spines of all the dorsal vertebræ above the eighth, and into the two lowermost cervical vertebræ. Its use is to extend the spine obliquely backward.

On the neck:

1. The semispinalis colli arises from the transverse processes of the six uppermost vertebræ of the back. It is inserted into the spines of all the cervical vertebræ, except the first and last. Its use is to extend the neck obliquely backward.

2. The multifidus spinæ arises from the side and spine of the sacrum, and from the posterior part of the ilium; from all the oblique and transverse processes of the lumbar vertebræ; from all the transverse processes of the dorsal vertebræ; and from those of the cervical, except the three first. It is inserted into all the spines of the lumbar, dorsal, and cervical vertebræ, except the first. Its use is to extend the vertebræ backward.

1. The interspinales colli arise from the spine of the inferior vertebræ of the neck, and ascend to be inserted into the spine of the superior vertebræ. They are five in number. Their use is to draw these processes nearer to each other.

2. The intertransversales colli arise from the inferior transverse process of each vertebra of the neck, and first of the back, and are inserted into the superior transverse processes. Their use is to draw these processes toward each other, and turn the neck to one side.

3, 4, and 5. The interspinales dorsi et lumborum, and the intertransversales dorsi, are rather small tendons than muscles, serving to connect the spinal and transverse processes.

6. The intertransversales lumborum are four distinct small bundles which fill up the spaces between the transverse processes of the lumbar vertebræ, and serve to draw them toward each other.

Muscles on the shoulder.

1. Deltoides arises from the clavicle, processus acromion and spine of the scapula. It is inserted into the anterior and middle part of the os humeri. Its use is to raise the arm.

2. Supraspinatus arises from the basis, spine, and upper costa of the scapula. It is inserted into a large tuberosity at the head of the os humeri. Its use is to raise the arm.

3. Infraspinatus arises from the basis and spine of the scapula. It is inserted into the upper and middle part of the tuberosity. Its use is to roll the os humeri outward.

4. Teres minor arises from the inferior costa of the scapula. It is inserted into the lower part of the tuberosity, and rolls the humerus outward.

5. Teres major arises from the inferior angle, and costa of the scapula. It is inserted into the ridge at the inner side of the groove formed for the long head of the biceps. Its use is to assist in the rotatory motion of the arm.

6. Subscapularis arises from the basis, superior and inferior costæ of the scapula. It is inserted into the upper part of a small tuberosity at the head of the os humeri. Its use is to roll the arm inward.

7. Coraco brachialis arises from the coracoid process of the scapula. It is inserted into the inner side of the os humeri. Its use is to raise the arm forward and upward.

Muscles on the arm.

1. Biceps flexor cubiti arises by two heads, one from the coracoid process, and the other, or long head, from the upper and outer edge of the glenoid cavity of the scapula. It is inserted into the tuberosity at the upper end of the radius. Its use is to bend the fore arm.

2. Brachialis internus arises from the os humeri, below, and at each side of the tendon of the deltoides. It is inserted into a small tuberosity at the fore part of the coronoid process of the ulna, and into the upper and outer part of the olecranon. Its use is to assist in bending the fore arm.

3. Triceps extensor cubiti arises by three heads: the first from the inferior costa of the scapula; the second from the upper and outer part of the os humeri; and the third from the back part of that bone.

Muscles on the fore arm.

1. Supinator longus arises from the ridge and anterior surface of the os humeri, a little above its outer condyle. It is inserted into the radius near its styloid process. Its use is to assist in turning the palm of the hand upward.

2. Extensor carpi radialis longus arises immediately below the origin of the supinator longus. It is inserted into the upper part of the metacarpal bone of the middle finger. Its use is to assist the extensor longus.

3. Extensor carpi radialis brevis arises from the outer and lower part of the outer condyle and the upper part of the radius. It is inserted into the back part of all the bones of the four fingers. Its use is to extend the fingers.

4. Extensor digitorum communis arises from the outer condyle of the os humeri. It is inserted into the back part of all the bones of the four fingers.

5. Extensor minimi digiti arises from the outer condyle of the os humeri. It is inserted into the bones of the little finger. Its use is to extend the little finger.

6. Extensor carpi ulnaris arises from the condyle of the os humeri. It is inserted into the metacarpal bone of the little finger. Its use is to assist in extending the wrist.

7. Anconæus arises from the outer condyle of the os humeri. It is inserted into the outer edge of the ulna. Its use is to extend the fore arm.

8. Flexor carpi ulnaris arises from the inner condyle of the os humeri, and anterior edge of the olecranon. It is inserted into the os pisiforme. Its use is to assist in bending the hand.

9. Palmaris longus arises from the inner condyle of the os humeri. It is inserted into the internal annular ligament. Its use is to bend the hand.

10. Flexor carpi radialis arises from the inner condyle of the os humeri. It is inserted into the metacarpal bone of the fore finger. Its use is to bend the hand.

11. Pronator radii brevis arises from the outer condyle of the os humeri, and coronoid process of the ulna. It is inserted into the anterior and convex edge of the radius, near its middle. Its use is to roll the hand inward.

12. Flexor sublimis perforatus arises from the inner condyle of the os humeri, inner edge of the coronoid process of the ulna, and upper and anterior part of the radius. It is inserted into the second bone of each finger. Its use is to bend the second joint of the fingers.

13. Supinator radii brevis arises from the outer condyle of the os humeri, the posterior surface and outer edge of the ulna. It is inserted into the anterior, inner, and upper part of the radius. Its use is to roll the radius outward.

14. Abductor pollicis longus arises from the middle and back part of the ulna, interosseous ligament, and radius. It is inserted by two tendons into the os trapezium, and first bone of the thumb. Its use is to stretch the first bone of the thumb outward.

15. Extensor minor pollicis arises from the back part of the ulna, and interosseous ligament and radius. It is inserted into the convex part of the second bone of the thumb. Its use is to extend the second bone of the thumb obliquely outward.

16. Extensor major pollicis arises from the back part of the ulna and interosseous ligament. It is inserted into the third and last bone of the thumb. Its use is to stretch the thumb obliquely backward.

17. Indicator arises from the middle of the ulna. It is inserted into the metacarpal bone of the fore finger. Its use is to extend the fore finger.

18. Flexor profundus perforans arises from the upper and fore part of the ulna, and interosseous ligament. It is inserted into the fore part of the last bone of each of the fingers. Its use is to bend the last joint of the fingers.

19. Flexor longus pollicis arises from the upper and fore part of the radius. It is inserted into the last joint of the thumb. Its use is to bend the last joint of the thumb.

20. Pronator radii quadratus arises from the inner and lower part of the ulna. It is inserted into the radius, opposite to its origin. Its use is to roll the radius inward, and, of course, to assist in the pronation of the hand.

Muscles on the hand.

1. Lumbricales arise from the tendons of the perforans. They are inserted into the tendons of the extensor digitorum communis. Their use is to bend the first, and to extend the two last joints of the fingers.

2. Abductor brevis pollicis arises from the fore part of the internal annular ligament, os scaphoides, and one of the tendons of the abductor longus pollicis. It is inserted into the outer side of the second bone of the thumb, near its root. Its use is to move the thumb from the fingers.

3. Opponens pollicis arises from the inner and anterior part of the internal annular ligament, and from the os scaphoides. It is inserted into the first bone of the thumb. Its use is to move the thumb inward, and to turn it upon its axis.

4. Flexor brevis pollicis arises from the os trapezoides, internal annular ligament, os magnum, and os unciforme. It is inserted into the ossa sesamoidea and second bone of the thumb.

5. Abductor pollicis arises from the metacarpal bone of the middle finger. It is inserted into the basis of the second bone of the thumb. Its use is to bend the second joint of the thumb.

6. Abductor indicis arises from the inner side of the first bone of the thumb, and from the os trapezium. It is inserted into the first bone of the fore finger posteriorly. Its use is to move the fore finger toward the thumb.

7. Palmaris brevis arises from the internal annular ligament, and aponeurosis palmaris. It is inserted into the os pisiforme, and the skin covering the abductor minimi digiti. Its use is to contract the palm of the hand.

8. Abductor minimi digiti arises from the internal annular ligament and os pisiforme. It is inserted into the side of the first bone of the little finger. Its use is to draw the little finger from the rest.

9. Flexor parvus minimi digiti arises from the os unciforme, and internal annular ligament. It is inserted into the first bone of the little finger. Its use is to bend the little finger.

10. Abductor metacarpi minimi digiti arises from the os unciforme, and internal annular ligament. It is inserted into the metacarpal bone of the little finger. Its use is to move that bone toward the rest.

11. Interossei interni, situated between the metacarpal bones. They are inserted into the roots of the fingers. Their use is to extend the fingers and move them toward the thumb.

12. Interossei externi, situated between the metacarpal bones on the back of the hand. They are inserted into the roots of the fingers. Their use is to extend the fingers; but the first draws the middle finger inward, the second draws it outward, and the third draws the ring finger inward.

Muscles on the upper part of the thigh.

1. Glutæus maximus arises from the spine of the ilium, posterior sacro ischiatic ligaments, os sacrum, and os coccygis. Inserted into the upper part of the linea aspera of the os femoris. Its use is to extend the thigh and draw it outward.

2. Glutæus medius, arises from the spine and superior surface of the ilium. It is inserted into the outer and back part of the great trochanter. Its use is to draw the thigh outward and a little backward, and when it is bended, to roll it.

3. Glutæus minimus, from the outer surface of the ilium, and the border of its great niche. It is inserted into the upper and interior part of the great trochanter. Its use is to assist the former.

4. Pyriformis arises from the anterior part of the os sacrum. It is inserted into a cavity at the root of the trochanter major. Its use is to roll the thigh outward.

5. Gemini arises by two portions, one from the outer surface of the spine of the ischium, the other from the tuberosity of the ischium, and posterior sacro ischiatic ligament. It is inserted into the same cavity as the pyriformis. Its use is to roll the thigh outward, and likewise to confine the tendon of the obturator internus, when the latter is in action.

6. Obturator internus arises from the superior half of the inner border of the foramen thyroideum. It is inserted into the same cavity with the former. Its use is to roll the thigh outward.

7. Quadratus femoris arises from the tuberosity of the ischium. It is inserted into a ridge between the trochanter major and trochanter minor. Its use is to move the thigh outward.

Muscles on the thigh.

1. Biceps flexor cruris arises by two heads; one from the tuberosity of the ischium, the other from the linea aspera, near the insertion of the glutæus maximus. It is inserted into the upper and back part of the fibula. Its use is to bend the leg.

2. Semitendinosus arises from the tuberosity of the ischium. It is inserted into the upper and inner part of the tibia. Its use is to bend and draw the leg inward.

3. Semimembranosus arises from the tuberosity of the ischium. It is inserted into the upper and back part of the head of the tibia. Its use is to bend the leg.

4. Tensor vaginæ femoris arises from the superior and anterior spinous process of the ilium. It is inserted into the inner side of the fascia lata, which covers the outside of the thigh. Its use is to stretch the fascia.

5. Sartozius arises from the superior and anterior spinous process of the ilium. It is inserted into the upper and inner part of the tibia. Its use is to bend the leg inward.

6. Rectus arises by two tendons; one from the anterior and inferior spinous process of the ilium, the other from the posterior edge of the cotyloid cavity. It is inserted into the upper and fore part of the rotula. Its use is to extend the leg.

7. Gracilis arises from the fore part of the ischium and pubis. It is inserted into the upper and inner part of the tibia. Its use is to bend the leg.

8. Vastus externus arises from the anterior and lower part of the great trochanter, and the outer edge of the linea aspera. It is inserted into the upper and outer part of the rotula. Its use is to extend the leg.

9. Vastus internus arises from the inner edge of the linea aspera, beginning between the fore part of the os femoris and the root of the lesser trochanter. It is inserted into the outer and inner part of the rotula. Its use is to extend the leg.

10. Cruræus arises from the outer and anterior part of the lesser trochanter. It is inserted into the upper part of the rotula. Its use is to extend the leg.

11. Pectinalis arises from the anterior edge of the os pubis. It is inserted into the upper and fore part of the linea aspera. Its use is to draw the thigh inward, upward, and to roll it a little outward.

12. Adductor longus femoris arises from the upper and fore part of the os pubis. It is inserted near the middle and back part of the linea aspera. Its use is to draw the thigh inward, upward, and to roll it a little outward.

13. Adductor brevis femoris arises from the fore part of the ramus of the os pubis. It is inserted into the inner and upper part of the linea aspera.

14. Adductor magnus femoris arises from the lower and fore part of the ramus of the os pubis. It is inserted into the whole length of the linea aspera.

15. Obturator externus arises from part of the obturator ligament, and the inner half of the circumference of the foramen thyroideum. It is inserted into the os femoris, near the root of the great trochanter. Its use is to move the thigh outward in an oblique direction, and likewise to bend and draw it inward.

Muscles on the leg.

1. Gastrocnemius externus arises by two heads; one from the inner condyle, the other from the outer condyle of the os femoris. It is inserted by a great round tendon, common to this and the following muscle. Its use is to extend the foot.

2. Gastrocnemius internus arises by two heads; one from the back part of the head of the fibula, the other from the upper and back part of the tibia. It is inserted by a large tendon, (the tendo Achillis,) common to this and the former muscle, into the lower and back part of the os calcis. Its use is to extend the foot.

3. Plantaris arises from the upper and posterior part of the outer condyle of the os femoris. It is inserted into the inside of the back part of the os calcis. Its use is to assist in extending the foot.

4. Popliteus arises from the outer condyle of the thigh. It is inserted into the upper and inner part of the tibia. Its use is to assist in bending the leg and rolling it inward.

5. Flexor longus digitorum pedis arises from the upper and inner part of the tibia. It is inserted by four tendons, which, after passing through the perforations in those of the flexor digitorum brevis, are inserted into the last bone of all the toes, except the great toe. Its use is to bend the last joint of the toe.

6. Flexor longus pollicis pedis arises from the back part, and a little below the head of the fibula. It is inserted into the last bone of the great toe. Its use is to bend the great toe.

7. Tibialis posticus arises from the back part and outer edge of the tibia, and likewise from the interosseous ligament and adjacent part of the fibula. It is inserted into the inner and upper part of the os naviculare, and side of the os cuneiforme medium. Its use is to move the foot inward.

8. Peroneus longus arises from the outer side of the head of the tibia, and also from the upper anterior and outer part of the fibula, to which it adheres for a considerable way down. It is inserted into the metatarsal bone of the great toe. Its use is to extend and to move the foot outward.

9. Peroneus brevis arises from the outer and fore part of the fibula. It is inserted into the metatarsal bone of the little toe. Its use is to assist the last described muscle.

10. Extensor longus digitorum pedis arises from the upper, outer, and fore part of the tibia, interosseous ligament, and inner edge of the fibula. It is inserted by four tendons into the first joint of the smaller toes. Its use is to extend the toes.

11. Peroneus tertius arises from the fore part of the lower half of the fibula, and from the interosseous ligament. It is inserted into the metatarsal bone of the little toe. Its use is to bend the foot.

12. Tibialis anticus arises from the upper and fore part of the tibia. It is inserted into the os cuneiforme internum. Its use is to bend the foot.

13. Extensor proprius pollicis pedis arises from the upper and fore part of the tibia. It is inserted into the convex surface of the bones of the great toe. Its use is to extend the great toe.

Muscles on the foot.

1. Extensor brevis digitorum pedis arises from the upper and anterior part of the os calcis. It is inserted by four tendons; one of which joins the tendon of the externus longus pollicis, and the other three the tendons of the extensor digitorum longus. Its use is to extend the toes.

2. Flexor brevis digitorum pedis arises from the lower part of the os calcis. It is inserted by four tendons, which, after affording a passage to those of the flexor longus, are inserted into the second phalanx of each of the small toes. Its use is to bend the second joint of the toes.

3. Abductor pollicis pedis arises from the inner and lower part of the os calcis. It is inserted into the first joint of the great toe. Its use is to move the great toe from the other toes.

4. Abductor minimi digiti arises from the outer tubercle of the os calcis, the root of the metatarsal bone of the little toe, and also from the aponeurosis plantaris. It is inserted into the outer side of the first joint of the little toe. Its use is to draw the little toe outward.

5. Lumbricalis pedis arises from the tendons of the flexor longus digitorum pedis. It is inserted into the tendinous expansion, at the part of the toes. Its use is to draw the toes inward.

6. Flexor brevis pollicis pedis arises from the inferior and anterior part of the os calcis, and also from the inferior part of the cuneiforme externum. It is inserted by two tendons into the first joint of the great toe. Its use is to bend that joint.

7. Adductor pollicis pedis arises from near the roots of the metatarsal bones of the second, third, and fourth toes. It is inserted into the outer sesamoid bone, or first joint of the great toe. Its use is to draw the great toe nearer to the rest, and also to bend it.

8. Transversales pedis arises from the outer and under part of the anterior end of the metatarsal bone of the little toe. It is inserted into the inner os sesamoideum and anterior end of the metatarsal bone of the great toe. Its use is to contract the foot.

9. Flexor brevis minimi digiti pedis arises from the basis of the metatarsal bone of the little toe. It is inserted into the first joint of the little toe. Its use is to bend the little toe.

10. Interossei pedis interni et externi, situated between the metatarsal bones.

Splanchnology explains the doctrine of the viscera. These are, according to their situation, divided into thoracic, abdominal, and pelvic. The cavity of the thorax is divided into five lesser cavities, *viz.* the anterior cavity of the mediastinum, the posterior cavity of the mediastinum, the cavity of the pericardium, and the right and left cavities of the thorax. The contents of the thorax are the pleura, pericardium, heart, lungs and bronchiæ, thymus gland, œsophagus, thoracic duct, arch of the aorta, descending cava, vena azygos, par vagum, and great intercostal nerve. The pleura is, from its situation, lining the ribs, or covering the lungs, divided into pleura pulmonalis, and costalis. The pericardium, or capsule of the heart, exhales from its internal surface a vapour which in the dead subject forms the aqua pericardii. The heart consists of a base, sides, and an apex; its right side being also anterior, and its left posterior; the auricles are placed toward its base, the ventricles extend to its apex; the last mentioned cavities contain the columnæ carniæ and chordæ tendineæ, give exit to the great arteries, and are separated from the auricles by the tricuspid valves, while the mouths of the arteries are protracted by the semilunar valves; the right auricle contains the musculi pectinati, tuberculum Loweri, fossa ovalis, Eustachian valve, and opening of the coronary vein, as well as the terminations of the venæ cavæ; the left auricle contains the openings of the pulmonary veins: the auricles are separated by the septum auriculorum, the ventricles by the septum ventriculorum. The lungs consist of a right and left; the right having three lobes, the left only two; the bronchiæ continued from the trachia, and consisting of smaller cartilaginous circles, divided into capillary tubes, which terminate in the vesiculæ bronchiales; the combination of these vesicles form the lobuli, which are connected by the interlobular substance. The thymus gland is peculiar to the fetus, nor has its duct been discovered. The œsophagus is a membranous and muscular canal, requiring no particular description; and the thoracic duct, arch of the aorta, &c. as well as the minutiæ of the thoracic viscera in general, are described elsewhere. The mammæ on the external part of the thorax consist of a body containing the mammary gland and lactiferous ducts, an areola, and a papilla or nipple.

Before describing the abdominal viscera, we may enumerate the salival glands, as they also are referrible to the article splanchnology. They are the parotid, maxillary, sublingual, thyroid, molar, buccal, labial, lingual, amygdaline, palatine, uvular, arytenoid, &c. the names of most of which explain their situation. The mouth, fauces, pharynx, and œsophagus, are the continuations of one cavity.

The abdomen is divided into the epigastric, hypochondriac, umbilical, epicholic, hypogastric, and inguinal

regions. Its contents are the peritoneum and its productions, the stomach, the small and large intestines, the liver and gall bladder, the spleen and the pancreas, the kidneys, ureters, &c. The chief productions of the peritoneum are the great and small omentum and the mesentery, supporting and conveying the vessels to the intestines. The stomach consists of a great and small curvature, a great and small extremity, one orifice named cardiac, and another termed pylorus. The small intestines consist of the duodenum, distinguished by its valvulæ conniventes and glandulæ Brumeri, the jejunum, remarkable for its ligamentary band, valvulæ conniventes, and plexus glandulosi Peyeri, and the ileum, distinguished also by its ligamentary band, but having less prominent valves and glands. The great intestines consist of the cæcum, which possesses an appendix, and has upon it the commencement of three ligamentary bands of the colon, consisting of an ascending, transverse, and descending portion, and having externally appendices epiploicæ, and strong ligamentary bands, and internally valvulæ conniventes forming between them the cells of the colon, and that valve which has been called the great valve of the colon, cæcum, or ileum, and of the rectum terminating in the anus. The liver consists of two great and one small lobe, termed lobulus Spigellii; it has a middle, right, left, and a round ligament; its internal structure is composed of the penecilli, or terminations of the venæ portæ, the pori biliarii, in which the bile is secreted, and the hepatic ducts, which terminate in one trunk, and convey the bile from the liver. The gall bladder consists of a fundus, a body, and a neck, which terminates in the duct called cysticus, and this joining the hepatic, they form together the ductus communis choledochus. The spleen is not properly understood, either in its structure or uses. The pancreas resembles in structure the salivary glands, and possesses a duct which terminates together with the ductus communis choledochus, in the duodenum. The kidneys are placed behind the peritoneum, and consist internally of a papillary, and externally of a cortical substance, while their middle part is striated; their internal cavity is called pelvis, and opens into the ureter. The renal capsules are placed at the upper part of the kidney, and their uses are unknown.

The pelvic viscera consist of the urinary bladder, and the male and female organs of generation. The bladder consists of a fundus or bottom, a body, and a neck; its coats are a muscular, a cellular, and a villous. The male organs of generation consist of the testis, which has three coats, the tunica vaginalis, the cremaster, and the tunica albuginea, the internal structure of which consists of delicate tubes, membranous septa, cells, and semeniferous ducts, terminating in the epididymis. This convoluted vessel afterward assumes the name of vas deferens, and opens within the prostate gland along with the vesiculæ seminales, which are apparently cellular, but in reality tubular bodies, placed between the rectum and inferior part of the bladder. The prostate gland is situated between the neck of the bladder and the bulb of the urethra; the small projection on its inner surface is named caruncula, or verumontanum, and on each side of it several ducts open from the gland. The penis itself consists of the corpora cavernosa on each side, the urethra inferiorly, the corpus spongiosum surrounding the former, the glans penis terminating the corpus spongiosum, and the integuments and preputium, which invest the whole. The female organs of generation consist of the pubes, or mons Veneris, the labia, the clitoris consisting of two crura and a body, the nymphæ internal to the labia, the urethra much shorter than that of the male, and having similar lacunæ, and the vagina, which in virgins contains the hymen or circulus membraneus, and in married women its remains called carunculæ myrtiformes. These are the external parts of generation in the female. The internal are the uterus and its appendages. The uterus consists of a neck, a body, and a fundus, and has a triangular cavity within it; its inferior aperture is called os tincæ. The ligamenta lata tie the uterus to the sides of the pelvis. The ovaria are fixed by the round ligaments to its corners, and the Fallopian tubes proceed from its fundus toward the sides of the pelvis, terminating in a fimbriated manner, and being enveloped, as well as the ovaria, in the broad ligaments.

Angiology, or the doctrine of the vessels of the body, from αγγειον, a vessel, and λογος, a discourse, is divided into three parts, one which treats of the absorbents, another the arteries, and a third of the veins.

Of the absorbent system.

For the discovery of the principal parts of this system, we are chiefly indebted to Asellius, Pacquet, Rudbeck, Jolyffe, and Bartholin. Some of the vessels of which it consists had indeed been seen and mentioned by their predecessors, but it was in too cursory a manner to give them any title to the discovery.

Thus the lacteals had been seen in kids by Erasistratus, who calls them arteries, as we are informed by Galen: and the thoracic duct had been seen by Eustachius, who speaks of it as a vein of a particular kind.

In 1622, Asellius discovered those vessels on the mesentery, which, from their carrying a milk white fluid, he denominated lacteals. This discovery being made by opening a living dog, anatomists were thence encouraged to make experiments on living animals; and Pacquet, on opening a dog, in the year 1651, found a white fluid mixed with the blood in the right auricle of the heart: suspecting this fluid to be chyle, he endeavoured to determine how it got from the lacteals into the heart. This he found was by means of the ductus thoracicus, which he traced from the lacteals to the subclavian vein; and thus he clearly proved the existence of that duct which we now consider as the trunk of the system. Just before this time, the lacteal had been supposed to terminate in the liver, conformably to the idea which the physiologists of that period had adopted about the use of this organ, which, from the authority of the older anatomists, they believed was the viscus hæmatopoeticum, or received the chyle from the intestines to convert it into blood.

In the years 1651 and 1652, Rudbeck, Jolyffe, and Bartholin, discovered the other parts of this system, which, from their carrying a transparent and colourless fluid, are called the lymphatic vessels. Thus there was proved to exist in the animal body a system of small vessels, containing fluids very different from the blood, and opening into the sanguiferous vessels at the left subclavian vein.

After this period, Nuck added to our knowledge of this system, by his injections of the lymphatic glands: Ruysch, by his description of the valves of the lymphatic vessels; and Dr. Meckel, by his accurate account of the whole sys-

tem, and by tracing those vessels in many parts where they had not been before described.

Besides these, doctors Hunter and Monro have called the attention of the public to this part of anatomy in their controversy concerning the discovery of the office of the lymphatics.

When the lymphatic vessels were first seen and traced into the thoracic duct, it was natural for anatomists to suspect, that as the lacteals absorbed from the cavity of the intestines, the lymphatics, which are similar in figure and structure, might possibly do the same office with respect to the other parts of the body. And accordingly, Dr. Glisson, who wrote in 1654, supposed these vessels arose from cavities, and that their use was to absorb. And Frederick Hoffman has very explicitly laid down the doctrine of the lymphatic vessels being a system of absorbents. But anatomists in general have been of a contrary opinion; for from experiments, particularly such as were made by injections, they have been persuaded that the lymphatic vessels did not arise from cavities, and did not absorb, but were merely continuations from small arteries. The doctrine therefore that the lymphatics, like the lacteals, were absorbents, as had been suggested by Glisson and by Hoffman, has been revived by Dr. Hunter and by Dr Monro, who have controverted the experiments of their predecessors in anatomy, and have endeavoured to prove that the lymphatic vessels are not continued from arteries, but are absorbents.

To this doctrine, however, several objections were started, particularly by Haller; and it was found, before the doctrine of the lymphatics being a system of absorbents, could be established, it was first to be determined whether this system existed in other animals besides man and quadrupeds. Mr. Hewson claims the merit of having proved the affirmative of this question, by discovering the lymphatic system in birds, fish, and amphibious animals. The celebrated Soemmerring has observed, that these vessels are more than proportionably larger in tall men, and more than proportionably less in men of inferior stature.

The absorbent system consists of the lacteals, the lymphatic vessels, their common trunk, the thoracic duct, and the glands called conglobate.

The lacteals begin from the intestinal tube, and can, for the most part, be seen in a dog, or other large quadruped, that is killed two or three hours after eating, when they appear filled with a white chyle; but they do not always convey a fluid of this colour; for even in a dog, if opened long after a meal, they are found distended with a liquor that is transparent and colourless, like the lymph; and in birds the chyle is never found white, but always transparent. These vessels therefore might, with as much propriety, be called the lymphatics of the intestines.

The lymphatic vessels are small pellucid tubes, that have now been discovered in most parts of the human body. The fluid they contain is generally as colourless as water; a circumstance which procured them at first the name of ductus aquosi, and afterward that of vasa lymphatica. The course of the lymph, like that of the chyle, is from the extreme parts of the body toward the centre; and many of the lymphatic vessels lie close to the large blood vessels. If, therefore, a ligature be thrown round the large blood vessels of the extremities of a living animal, or of one just dead, that ligature, by embracing the lymphatics, will stop the course of the lymph, which, by distending the vessels, will make them visible below the ligature.

All the lacteals, and most of the lymphatic vessels, open into the thoracic duct, which lies upon the spine, and runs up toward the neck of the animal, where it commonly opens into the angle between the internal jugular and subclavian veins of the left side: and thus both the chyle and the lymph are mixed with the blood. If therefore a ligature be thrown round the thoracic duct immediately after killing an animal, not only the lacteal, but also the lymphatic vessels in the abdomen and lower extremities, become distended with their natural fluids.

The lacteals, the lymphatics, and the thoracic duct, all agree in having their coats thinner and more pellucid than those of the blood vessels. But although their coats are so thin, they are very strong: as we daily see on injecting them with mercury, since they resist a column of that fluid whose weight would make it burst through blood vessels, the coats of which are many times thicker than those of the lymphatic system.

The thinness of the coats prevents our dividing them from one another, and thereby ascertaining their number as we do those of the blood vessels. But as the blood vessels have a dense internal coat, to prevent transudation, we have reason to believe the lymphatics have the same. And as the blood vessels have a muscular coat, which assists in the circulation, so may the lymphatics. This is rendered probable from what Dr. Haller says of his having found them irritable in his experiments, and also from what is observed on seeing them in living animals distended with their lymph, in which case they appear of a considerable size; but upon emptying them of their contents, they contract so much as not to be easily distinguished. This experiment, Mr. Hewson informs us, he frequently made in the trunk of the lacteals in a goose, and on the lymphatic vessels on its neck; both of which, when distended with their natural fluids, are as large as a crow quill; but upon emptying them in the living animal, he has seen them contract so much, that it was with the greatest difficulty he could distinguish them from the fibres.

The coats of lymphatic vessels have, in common with all other parts of the body, arteries and veins for their nourishment. This is rendered probable by their being susceptible of inflammation; for they are frequently found in the form of a cord, painful to the touch, and extending from an ulcer to the next lymphatic gland. These painful swellings of lymphatic vessels likewise show that their coats have sensibility, and therefore that they have nerves as well as arteries and veins. Besides, we can clearly trace in different parts of the body, blood vessels running along their surfaces.

The lymphatic system in most animals, but particularly in man and quadrupeds, is full of valves. These valves have been painted by the celebrated Nuck, Ruysch, and others, and are much more frequent than in the common veins; and thence these lymphatics have sometimes been distinguished by the name of valvular lymphatic vessels. Those valves are generally two in number, are of a semilunar shape, and one is sometimes much larger than the other. In some parts of the body, these valves

are so numerous, that there are three or four pair in an inch of space; but sometimes there is no more than one pair, sometimes several inches of a lymphatic appear without a valve. They are less numerous in the thoracic duct than in the branches of the system. Thence it might be supposed, that in proportion as we go from the trunk to the branches, we should find them thicker set. But this is not always true; for Mr. Hewson observed them more numerous in the lymphatic vessels of the thigh than on those of the leg. When the vessels are distended with lymph, they appear larger on that side of the valves next the heart, which sometimes gives a lymphatic vessel an appearance of being made of a chain of vesicles; as such they are represented by some authors; but it is an appearance that very seldom occurs in the human body. In quadrupeds, however, this appearance is very remarkable. Wherever a lymphatic vessel enters the thoracic duct, we find either one or two valves which prevent the return of the lymph.

Lastly, the lymphatic system in different parts of its course has the glands, called conglobate or lymphatic. These glands are so placed, that the vessels come in on one side, and pass out on the other, in their way to the thoracic duct. They are commonly of an oval, though sometimes of a round shape, and frequently somewhat flattened, and of various sizes; some being no larger than a millet seed, while others are almost an inch in diameter. They vary in colour in different parts of the body, and at different times of life. In young people they are generally of a reddish or brown colour, but become paler with age. They have a shining external surface, which is owing to a smooth dense coat that covers them. Like other glands, they have arteries, veins, and nerves, which enter into their composition; but with respect to the rest of their structure, anatomists are much divided in opinion. Soemmerring has endeavoured to prove that they are partly cellular and partly vascular. That these glands are wanting in some animals is now known.

The absorbent system, besides the glands, is divided into three parts, *viz.* the lacteal, the lymphatic vessels and the lacteal sac, and the lymphatic duct. The lacteals belong to the intestinal tube, the lymphatics to all the other parts of the body, and the lacteal sac and thoracic duct is the common trunk which receives both the lacteals and lymphatics. We shall give a particular description of the latter from the celebrated Monro, as being that part of the absorbent system which is most important, both to the general reader and to the medical student.

"The receptaculum chyli, or saccus lacteus, is a membranous, somewhat pyriform bag, two thirds of an inch long, one third of an inch over in its largest part when collapsed; situated on the first vertebra of the loins of the right of the aorta, a little higher than the right emulgent artery, behind the right inferior muscle of the diaphragm; it is formed by the union of three tubes, one from under the aorta, the second from the interstice of the aorta and cava, the third from under the emulgents of the right side.

"The lacteal sac becoming gradually smaller toward its upper part, is contracted into a slender membranous pipe, of about a line diameter, which is generally named the thoracic duct. This passes betwixt the muscular appendices, or inferior muscles of the diaphragm, on the right of and somewhat behind the aorta; then being lodged in the cellular substance, behind the pleura, it mounts between the aorta and the vena azygos, as far as the fifth vertebra of the thorax, where it is hid by the azygos, as this vein rises forward to join the descending or superior cava; after which the duct passes obliquely over to the left side behind the œsophagus, aorta descendens, and the great curvature of the aorta, until it reaches the left carotid artery; behind which, on the left side of the œsophagus, it runs to the interstice of the first and second vertebræ of the thorax, where it begins to separate from the carotid, stretching further toward the left internal jugular vein by a circular turn, whose convex part is uppermost. At the top of this arch it splits into two for a line and a half; the superior branch receiving into it a large lymphatic vessel from the cervical glands. This lymphatic appears, by blowing air and injecting liquors into it, to have few valves. When the two branches are again united, the duct continues its course toward the internal jugular vein, behind which it descends, and immediately at the left side of the insertion of this vein, enters the superior posterior part of the left subclavian vein, whose internal membrane duplicated forms a semilunar valve, that is convex externally and covers two thirds of the orifice of the duct; immediately below this orifice, a cervical vein from the musculi scaleni enters the subclavian.

"The coats of the sac and duct are thin transparent membranes, from the inside of which, in the duct, small semilunar valves are produced most commonly in pairs, which are so situated, as to allow the passage of liquor upward, but oppose its return in an opposite course. The number of these is generally ten or twelve.

"This is the most simple and common course, situation, and structure, of the receptaculum chyli, and thoracic duct."

Of the heart, lungs, and arterial system.

Previous to describing the arterial system of the human body, it will be necessary to give a general account of the thorax and its contents.

By the thorax we commonly understand all that part of the body which answers to the extent of the sternum, ribs, and vertebræ of the back, both outwardly and inwardly.

The thorax is divided into the anterior part, called commonly the breast; the posterior part called the back, and the lateral parts called the right and left sides.

The internal parts of the thorax are contained in the cavity of the portion of the trunk, which is named the cavity of the breast. This cavity is lined by a membrane called pleura, which forms the mediastinum, and contains the heart and lungs, with the vessels, &c. which go into or out from them; through it likewise the œsophagus passes to the stomach, and part of the nerves are contained in it which go the contents of the abdomen.

Cavity of the thorax. The hard parts which form the sides of this cavity, are the twelve vertebræ of the back, all the ribs, and the sternum. The soft parts, which complete the sides, are, the membrane called pleura, which lines the cavity, and the musculi intercostales, sterno costales, and diaphragma, already described.

All these hard and soft parts taken together represent a kind of cage, in some measure of a conical figure, flatted on the fore side, depressed on the back side, and in a manner divided into two nooks, by the figure of the vertebræ

of the back, and terminated below a broad arched basis, inclined backward. The intercostal muscles fill up the intestines betwixt the ribs, and so complete the sides of the cavity. The basis is the diaphragm; and the pleura not only covers the whole inner surface of the cavity, but by forming the mediastinum, divides it into two, one on the right, the other on the left.

Pleura and mediastinum.

The pleura is a membrane which adheres very closely to the inner surface of the ribs, sternum, and musculi intercostales, sub costales, and sterno costales, and to the convex side of the diaphragm. It is of a very firm texture, and is supplied with blood vessels and nerves, in all which it resembles the peritonæum; and likewise in that it is made up of an inner true membranous lamina, and a cellular substance on the outside.

Each side of the thorax has its particular pleura entirely distinct from the other: and making, as it were, two great bladders, situated laterally with respect to each other in the great cavity of the breast; in such a manner as to form a double septum, or partition, running between the vertebræ and the sternum, their other sides adhering to the ribs and diaphragm.

This particular duplicature of the two pleuræ is termed mediastinum: the two laminæ of which it is made up are closely united together near the sternum and vertebræ; but in the middle, and toward the lower part of the fore side, they are separated by the pericardium and heart, as we shall see hereafter. A little more backward they are parted in a tubular form by the œsophagus, to which they serve as a covering; and in the most posterior part a triangular space is left between the vertebræ and the two pleuræ from above downward, which is filled chiefly by the aorta.

Before the heart, from the pericardium to the sternum, the two laminæ adhere very closely, and there the mediastinum is transparent, except for a small space near the upper part, where the thymus gland is situated, so that in this place there is naturally no interstice, or particular cavity. The apparent separation is owing entirely to the common method of raising the sternum, as was plainly demonstrated by Bartholinus in his treatise of the diaphragm, published at Paris in 1676.

The mediastinum does not commonly terminate along the middle of the inside of the sternum, as the common opinion has been. Muslow demonstrated, in the year 1715, to the Royal Academy of Sciences, that from above downward, it inclines toward the left side; and that if before the thorax is opened, a sharp instrument be run through the middle of the sternum, there will be almost the breadth of a finger between the instrument and the mediastinum, provided that the sternum remain in its natural situation, and the cartilages of the ribs be cut at the distance of an inch from it on each side.

From all this, we see not only that the thorax is divided into two cavities, entirely separated from each other by a middle septum, without any communication, but also that by the obliquity of this partition, the right cavity is greater than the left; but there are exceptions to the above descriptions. Lientand says he has met with several subjects in which the mediastinum descended along the middle of the sternum; and others, where it was inclined to the left side. Sabatier observes this is rare; but he has likewise met with several examples, where an instrument thrust through the middle of the sternum, got into the left cavity of the thorax. And he has sometimes seen the right lamina of the mediastinum fixed to the middle of the sternum, while the left one was fixed opposite to the articulation, with the cartilages of the ribs; a space being left between the two, which was filled with cellular substance intermixed with fat.

The pleura is connected to the membranous portion of the sternum, ribs, and muscles; to the diaphragm, pericardium, thymus gland, and vessels: and, in a word, to whatever lies near its convex side.

The surface of the pleura turned to the cavity of the breast, is continually moistened by a lymphatic serosity, which transudes through the pores of the membranous portion. This fluid is said to be secreted by imperceptible glands; but the existence of these glands has not been hitherto demonstrated.

Use. The pleura serves in general for an inner integument to the cavity of the thorax. The mediastinum cuts off all communication between the two cavities, and hinders one lung from pressing on the other when we lie on one side. It likewise forms receptacles for the heart, pericardium, œsophagus, &c. and it is continued over the lungs in the manner which shall be explained hereafter.

Before we leave the pleura it must be observed, that it adheres firmly to the ribs. This adhesion keeps the pleura stretched, and hinders it from slipping, or giving way. It likewise renders this membrane extremely sensible of the least separation, caused by a coagulable lymph or accumulated blood; the nervous filaments being likewise in this case very much compressed in inspiration by the swelling of the intercostal muscles.

Pericardium.

The heart, with all the parts belonging to it, is contained in a membranous capsula, called pericardium, which is, in some measure, of a conical figure, and somewhat bigger than the heart; but the difference must be less during life, when the heart is full of blood. It is not fixed to the basis of the heart, but round the large veins above the auricles, before they send off the ramifications, and round the large arteries before their division.

The pericardium is made up of three laminæ; the middle and chief of which is composed of very fine tendinous filaments, which are best seen in old persons; they are closely interwoven, and cross each other in different directions. The internal lamina seems to be a continuation of the outer coat of the heart, auricles, and great vessels. The trunks of the aorta and pulmonary artery have one common coat, which contains them both, as in a sheath, and is lined on the inside by a cellular substance, chiefly in that space which lies between where the trunks are turned to each other and the sides of the sheath. There is but a very small portion of the vena cava contained in the pericardium.

It is the middle lamina which chiefly forms the pericardium; and the figure of this bag is not simply conical, its apex or point being very round, and the basis having a particular elongation, which surrounds the great vessels, as has been already said, as amply as the other portion surrounds the heart.

The pericardium is closely connected to the diaphragm, not at the apex, but exactly at that place which answers to the flat or lower side of the heart; and it is a very difficult matter to separate it from the diaphragm in dissection, the tendinous fibres of the one substance intermixing with those of the other. This adhering portion is in some measure of a triangular shape, answering to that of the lower side of the heart; and the rest of the bag lies upon the diaphragm, without any adhesion.

The external lamina, or common covering, as it may be called more properly, is formed by the duplicature of the mediastinum. It adheres to the proper bag of the pericardium by the intervention of the cellular substance in that duplicature, but leaves it where the pericardium adheres to the diaphragm; on the upper surface of which it is spread, as being a continuation of the pleura.

The internal lamina is perforated by an infinite number of very small holes through which a serous fluid continually transudes, in the same manner as in the peritonæum, there being no glands for this purpose, as some have supposed. This fluid being generally collected after death, makes what is called aqua pericardii, which is found in considerable quantities in opening dead bodies while they remain fresh. Sometimes it is of a reddish colour, which may be owing to a transudation of blood through the fine membrane of the auricles.

Of the Heart.

Situation in general, and conformation. The heart is a muscular body situated in the cavity of the thorax on the anterior part of the diaphragm between the two laminæ of the mediastinum. It is in some measure of a conical figure flatted on the sides, round at the top, and oval at the basis. Accordingly we consider in the heart, the basis; the apex; two edges, the one right and the other left; and two sides, one of which is generally flat and inferior, the other more convex and superior.

Besides the muscular body, which forms what we chiefly call the heart, its basis is accompanied by two appendices called auriculæ, and by large blood vessels; of which hereafter: and all these are included in the pericardium.

The heart is hollow within, and divided by a septum which runs between the edges into two cavities called ventriculæ, one of which is thick and solid, the other thin and soft. This latter is generally termed the right ventricle, the other the left ventricle; though in their natural situation, the right ventricle is placed more anteriorly than the left, as we shall see hereafter.

Each ventricle opens to the basis by two orifices; one of which answers to the auricles, the other to the mouth of a large artery; and accordingly, one of them may be termed the auricular orifice, the other the arterial orifice. The right ventricle opens into the right auricle, and into the trunk of the pulmonary artery; the left into the left auricle, and into the great trunk of the aorta. At the edges of these orifices are found several moveable pelliculæ, called valves, of which some are turned inward toward the cavity of the ventricles called the tricuspid; others are turned toward the great vessels, called semilunar, or sigmoid. The tricuspid valves of the left ventricle are likewise termed mitral.

Ventricles. The inner surface of the ventricles is very uneven, many eminences and cavities being observable therein. The most considerable eminences are thick fleshy productions, called columnæ carniæ, fleshy columns. To the extremities of these pillars are fastened several chordæ tendinæ, tendinous cords, the other ends of which are joined to the valvulæ tricuspides. There are likewise other small short tendinous ropes along both edges of the septum, between the ventricles. These small cords lie in an obliquely transverse situation, and form a kind of net work at different distances.

The cavities of the inner surface of the ventricles are small deep fossulæ or lacunæ placed very near each other, with small prominent interstices between them. The greatest part of these lacunæ are orifices of the vernal duct, to be described hereafter.

Structure of the ventricles. The fleshy or muscular fibres of which the heart is made up, are disposed in a very singular manner, especially those of the right or anterior ventricle, being either bent into arches or folded into angles.

The fibres which are folded into angles are longer than those which are only bent into arches. The middle of these arches and the angles of the folds are turned toward the apex of the heart, and the extremities of the fibres toward the basis. These fibres differ not only in length; but in their directions, which are very oblique in all, but much more so in the long or folded fibres than in the short ones which are simply bent.

It is commonly said, that this obliquity represents the figure 8; but the comparison is very false, and can only agree to some bad drawings made by persons ignorant of the laws of perspective.

All these fibres, regard being had to their different obliquity and length, are disposed in such a manner as that the longest form partly the most external strata of the convex side of the heart, and partly the most internal on the concave side, the middle of the arches and the angles meeting obliquely and successively to form the apex.

The fibres situated within these long ones, grow gradually shorter and straighter all the way to the basis of the heart, where they are very short and very little incurvated. By this disposition, the sides of the ventricles are very thin near the apex of the heart, and very thick toward the basis.

Each ventricle is composed of its proper distinct fibres; but the left ventricle has many more than the right, its substance being considerably thicker. Where the two ventricles are joined, they form an impervious septum which belongs equally to both. Opposite to this septum a groove is seen on the outside of the heart, one running longitudinally on the upper, the other on the under surface; in these grooves the great branches of the coronary arteries and veins are lodged.

There is this likewise peculiar to the left ventricle, that the fibres which form the innermost septum of its concave side, form the outermost stratum of the whole convex side of the heart, which consequently is common to both ventricles; so that by carefully unravelling all the fibres of the heart, we find it to be made up of two bags contained in a third.

The anterior or right ventricle is somewhat larger than the posterior or left, as well observed by the ancients, and clearly demonstrated by M. Helvetius.

The left is a little longer than the right, and in some subjects they end exteriorly in a kind of double apex.

But it appears from experiments, that the inequality between the parts of the right and those of the left side of the heart, is not so great during life as after death; for in the hearts of animals killed by cutting across the vessels of the neck, and in those of persons who have died in battle from a wound in the vena cava, or pulmonary artery, the inequality is less than we commonly perceive. This was first observed by M. Vieussens, professor of anatomy at Altorf.

Sabatier has made several experiments on animals, the result of which is nearly the same with that mentioned above.

All the fibres are not directed the same way, though they are all more or less oblique: for some end toward the right hand, others toward the left, some forward, some backward, and others in the intermediate places; so that in unravelling them, we find that they cross each other gradually, sometimes according to the length of the heart, and sometimes according to its breadth.

The tubes which cross each other transversely, are much more numerous than those which cross longitudinally: which ought to be taken notice of, that we may rectify the false notions that have been entertained concerning the motion of the heart; namely, that it is performed by a contortion or twisting like that of a screw, or that the heart is shortened in the time of contraction, and lengthened in dilation.

The fibres which compose the inner or concave surface of the ventricles do not all reach to the basis; some of them running into the cavity and there forming the fleshy columns to which the loose floating portion of the tricuspidal valves is fastened by tendinous cords.

Besides these fleshy pillars the internal fibres form a great many eminences and depressions, which not only render the inner surface of the ventricles uneven, but give it a great extent within a small compass. Some of these depressions are the orifices of the venal ducts, found in the substance of the ventricles, which have been already mentioned. The circumference of the great openings of the basis of the heart are tendinous, and may be looked upon as the common tendon of all the fleshy fibres, of which the ventricles are composed.

Valves. The valves at the orifices of the ventricles are of two kinds; one kind allows the blood to enter the heart, and hinders it from going out the same way; the other kind allows the blood to go out of the heart, but hinders it from returning. The valves of the first kind terminate the auricles; and those of the second lie in the openings of the great arteries. The first are termed semilunar or sigmoid valves; the others tricuspidal or mitral.

The tricuspidal valve of the right ventricle is of a circular form, and is fixed to the opening of the auricle, while the other end is attached to the internal surface of the ventricle. The circular membrane of the valve soon divides into many parts, three of which are more considerable than the rest; and these have got the name of tricuspid valves, though they are now generally considered as forming one. That which is next the mouth of the pulmonary artery is the largest, and is said by some to prevent the blood from getting into the artery, while the ventricle is filling. It has three triangular productions, very smooth and polished, on that side which is turned toward the auricle; and on the side next the cavity of the ventricle, they have several membranous and tendinous expansions, and their edges are notched or indented. The valve of the auricular orifice of the left ventricle is of the same shape and structure, but it is only divided into two parts; and, from some small resemblance to a mitre, has been named mitralis. That which is next the mouth of the aorta is the largest.

The semilunar valves are six in number, three belonging to each ventricle, situated at the mouths of the great arteries, and they may be properly enough named valvulæ arteriales. Their concave sides are turned toward the cavity of the arteries, and their convex sides approach each other. In examining them with a microscope, we find fleshy fibres lying in the duplicature of the membranes of which they are composed.

They are truly semilunar, or in form of a crescent on that side by which they adhere; but their loose edges are of a different figure, each of them representing two small crescents; the two extremities of which meet at the middle of this edge, and there form a kind of small papilla, first described by Arantius, and afterward by Morgani, and therefore named from them.

The great artery that goes out from the left ventricle is termed aorta. At the beginning of the aorta, and behind the semilunar valves, three elevations are observed on the outside; these correspond to an equal number of pits on the inside, which from the discoverer have been called sinuses of Valsolva. Their use is not well known.

The trunk of the artery which goes out from the right ventricle is called arteria pulmonaris. This trunk, as it is naturally situated in the thorax, runs first of all directly upward for a small space, then divides laterally into two principal branches, one for each lung; that which goes to the right lung being the longest, for a reason that shall be given hereafter.

Auricles. The auricles are muscular bags situated at the basis of the heart, and their capacities are in proportion to those of their respective ventricles; one toward the right ventricle, the other toward the left, and joined together by an inner septum, and external communicating fibres, much in the same manner with the ventricles; one of them being named the right auricle, the other the left. They are very uneven on the inside, but smoother on the outside, and terminate in a narrow, flat, indented edge, representing a cock's comb, or in some measure the ear of a dog; this properly gets the name of auricle, the larger and smooth part of the cavity being called sinus venosus; but as the two parts make one general cavity, the name of auricle is commonly applied to the whole. They open into the orifices of each ventricle, which I name auricular orifices; and they are tendinous at their openings, in the same manner as the ventricles.

The right auricle is larger than the left, and joins the right ventricle by a common tendinous opening, as has been already observed. It has two other openings united into one, and formed by two large veins which meet and terminate there almost in a direct line, called vena cava, superior and inferior. Highmore has described an eminence in form of a valve, placed between the mouths of the two venæ cavæ: this he supposed directs the blood from the veins into the auricle; afterward Lower described and delineated it; and other anatomists have called it tuberculum Loweri, till Morgagni denied its existence in

the human subject. At the mouth of the inferior cava, we find a membrane in form of a crescent, described by Eustachius, and named from him. Its convex edge is fixed to the union of the vein and right auricle, while its concave edge is turned upward over the mouth of the vein. It is most complete in the fetus; but it is found likewise in a person of advanced age, though it sometimes from use has a reticular appearance. It is said to prevent the blood in the auricle from returning into the cava; but it has a different use in the fetus. The notched edge of this auricle terminates obliquely in a kind of obtuse point, which is a small particular production of the great bag, and is turned toward the middle of the basis of the heart.

The whole inner surface of the right auricle is uneven, by reason of a great number of prominent lines which run across the sides of it, and communicate with each other by smaller lines which lie obliquely in the intestines between the former. The lines of the first kind represent trunks, and the other small branches run in an opposite direction to each other: these are called musculi pectinati. In the interstices between these lines the sides of the auricle are very thin and almost transparent, seeming to be formed merely by the external and internal coats of the auricle joined together, especially near the point.

The left auricle is in the human body a kind of muscular bag or reservoir of a pretty considerable thickness, and unequally square, into which the four veins open called venæ pulmonares, and which has a distinct appendix belonging to it like a third small auricle. This bag is very even on both surfaces, and is therefore called sinus venosus; but to distinguish it from the one on the right side, it is called sinus venosus sinister. However, the bag and appendix have but one common cavity, and therefore may still be both comprehended under the common name of left auricle. In men the small portion may likewise be named the appendix of the left auricle; but in other animals the case is different.

This small portion or appendix of the left auricle is of a different structure from that of the bag or large portion. Exteriorly it resembles a small oblong bag bent different ways, and indented quite round the edges. Interiorly it is like the inside of the right auricle. The whole common cavity of the left auricle is smaller in an adult subject than that of the right; and the fleshy fibres of the left auricle cross each other obliquely in strata differently disposed.

Coronary arteries and veins. Besides the great common vessels, the heart has vessels peculiar to itself called the coronary arteries and veins, because they in some measure crown the basis of the heart. The coronary arteries, which are two in number, go out from the beginning of the aorta, and afterward spread themselves round the basis of the heart, to the substance of which they send numerous ramifications.

Vieussens believed that some of the branches of the coronary artery opened into the cavities of the ventricles and auricles; for by throwing a fine injection into these arteries, he found it run out into all sides of the right ventricle and auricle. Thebesius of Allemand being nearly of the same opinion, endeavoured to prove that there were veins which carried part of the blood from the coronary arteries immediately into the cavities of the heart; and these have therefore got the name of veins of Thebesius, though he is not the first discoverer. Winslow, Haller, and several others describe such veins; but Duverney, after injecting the heart of an elephant, doubts of their existence. Senac, who has paid much attention to this subject, denies it altogether; and Sabatier coincides with him in opinion.

There are seldom more than two arteries, of which one lies toward the right hand, the other toward the left of the anterior third part of the circumference of the aorta. The right coronary artery runs in between the basis and right auricle, all the way to the flat side of the heart, and so goes half way round. The left artery has a like course between the basis and left auricle, and before it turns on the basis, it sends off a capital branch which runs in between the two ventricles. Another principal branch goes off from the union of the two arteries on the flat side of the heart, which running to the apex, there joins the other branch.

The coronary veins are distributed exteriorly much in the same manner. The largest opens into the posterior inferior part of the right auricle, by an orifice which is furnished with a valve first described by Eustachius. Besides the coronary veins, the heart has other anterior veins, which have been called by Vieussens, venæ innominatæ. Some of them go into the right auricle, others end in the right ventricle; and there are other veins still smaller, which are found in the substance of the heart, and which terminate in the right sinuses and auricle.

Particular situation of the heart. The heart lies almost transversely on the diaphragm, the greatest part of it being in the left cavity of the thorax, and the apex being turned toward the bony extremity of the sixth true rib. The basis is toward the right cavity; and both auricles, especially the right, rest on the diaphragm; but the situation of the heart during life changes a little, according to the state of respiration, and to the position of the body.

The origin or basis of the pulmonary artery is, in this natural situation, the highest part of the heart on the fore side; and the trunk of this artery lies in a perpendicular plane, which may be perceived to pass between the sternum and spina dorsi. Therefore some part of the basis of the heart is in the right cavity of the thorax; and the rest, all the way to the apex, is in the left cavity; and it is for this reason that the mediastinum is turned toward that side.

According to this true and natural situation of the heart, the parts are commonly said to be on the right side, or rather anterior, and those on the left side posterior; and that side of the heart which is thought to be the fore side, is naturally the upper side, and the back side consequently the lower side.

The lower side is very flat, lying wholly on the diaphragm; but the upper side is a little convex through its whole length, in the direction of the septum, between the ventricles.

Uses in general. The heart, and parts belonging to it, are the principal instruments of the circulation of the blood. The two ventricles ought to be considered as two syringes, so closely joined together as to make but one body; and furnished with suckers, placed in contrary directions to each other, so that by drawing one of them a fluid is let in, and forced out again by the other.

Lungs.

Situation and general figure. The lungs are two large spongy bodies, of a reddish colour in children, grayish in adult subjects, and bluish in old age; filling the whole cavity of the thorax, one being seated in the right side, the other in the left, parted by the mediastinum and heart; and of a figure answering to that of the cavity which contains them; that is, convex next the ribs, concave next the diaphragm, and irregularly flatted and depressed next the mediastinum and heart.

Division and figure in particular. They are distinguished into the right and left lung; and each of these into two or three portions, called lobes, of which the right lung has commonly three, or two and a half, and the left lung two. The right lung is generally larger than the left, answerably to the cavity of the breast, and to the obliquity of the mediastinum.

In the lower edge of the left lung there is an indented notch or sinus, opposite to the apex of the heart, which is therefore never covered by that lung, even in the strongest respiration; and consequently the apex of the heart and pericardium may always strike against the ribs, the lungs not surrounding the heart in the manner commonly taught.

Structure. The substance of the lungs is almost all spongy, being made of an infinite number of membranous cells, and of different sorts of vessels spread among the cells in innumerable ramifications.

Coats. This whole mass is covered by a membrane continued from each pleura, which is commonly said to be double; but what is looked upon as the inner membrane, is only an expansion and continuation of a cellular substance, which shall be spoken of after we have described the vessels of the viscus.

Bronchia. The vessels which compose part of the substance of the lungs are of three or four kinds; the principal of these are air vessels and blood vessels. The air vessels make the chief part, and are termed bronchia.

These bronchia are conical tubes, composed of an infinite number of cartilaginous fragments, like so many irregular arches of circles, connected together by a ligamentary elastic membrane; and disposed in such a manner, that the lower easily insinuate themselves within those above them.

They are lined on the inside by a very fine membrane, which continually discharges a mucilaginous fluid; and in the substance of the membrane are a great number of small blood vessels, and on its convex side many longitudinal lines, which appear to be partly fleshy, and partly made up of an elastic substance of another kind.

The bronchia are divided, in all directions, into an infinite number of ramifications, which diminish gradually in size; and as they become capillary, change their cartilaginous structure into that of a membrane. Besides these very small extremities of this numerous series of ramifications, we find that all the subordinate trunks, from the greatest to the smallest, send out from all sides a vast number of short capillary tubes of the same kind.

Vesiculæ bronchiales. Each of these bronchial tubes is widened at the extremity, and thereby formed into a membranous cell, commonly called a vesicle. These cells or folliculi are closely connected together in bundles; each small branch producing a bundle proportionable to its extent, and the number of its ramifications.

Lobuli. These small vesicular or cellulous bundles are termed lobules; and as the great branches are divided into small rami, so the great lobules are divided into several small ones. The cells or vesicles of each lobule have a free communication with each other, but the several lobules do not communicate so readily.

Interlobular substance. The lobules appear to be distinctly parted by another cellular substance, which surrounds each of them in proportion to their extent, and fills up the interstices between them. This substance forms likewise a kind of irregular membranous cells, which are thinner, looser, and broader, than the bronchial vesicles.

This substance is dispersed through every part of the lungs, forms cellulous or spongy vaginæ, which surround the ramifications of the bronchia and blood vessels, and is afterward spread over the outer surface of each lung, where it forms a kind of fine cellular coat, joined to the general covering of that viscus.

When we blow into this interlobular substance, the air compresses and flattens the lobuli; and when we blow into the bronchial vesicles they presently swell; and if we continue to blow with force, the air passes insensibly into the interlobular substance. We owe this observation to M. Helvetius.

Vascular texture. All the bronchial cells are surrounded by a very fine reticular texture of the small extremities of arteries and veins, which communicate every way with each other. The greatest part of this admirable structure is the discovery of the illustrious Malphigi.

Blood vessels. The blood vessels of the lungs are of two kinds; one common, called the pulmonary artery and veins; the other proper, called the bronchial arteries and veins.

The pulmonary artery goes out from the right ventricle of the heart; and its trunk, having run directly upward as high as the curvature of the aorta, is divided into two lateral branches, one going to the right hand, called the right pulmonary artery; the other to the left, termed the left pulmonary artery. The right artery passes under the curvature of the aorta, and is consequently longer than the left. They both run to the lungs, and are dispersed through their whole substance by ramifications nearly like those of the bronchia, and lying in the same direction.

The pulmonary veins having been distributed through the lungs, in the same manner go out on each side by two great branches, which open laterally into the reservoir or muscular bag of the right auricle.

The ramifications of these two kinds of vessels in the lungs, are surrounded every where by the cellular substance already mentioned, which likewise gives them a kind of vagina; and the rete mirabile of Malphigi, described above, is formed by the capillary extremities of these vessels. It must be observed, that the ramifications of the arteries are more numerous and larger than those of the veins, which in all other parts of the body exceed the arteries both in number and size.

Bronchial arteries and veins. Besides these capital blood vessels, there are others called the bronchial arteries and veins, which are very small, but they follow the bronchia through all their ramifications. They commu-

nicate with the pulmonary arteries and veins in many places, likewise with the arteries and veins of the œsophagus, and with branches of the coronary artery and vein. These are nutrient vessels of the lungs.

Ligaments. Under the root of each lung, that is, under that part formed by the subordinate trunk of the pulmonary artery, by the trunks of the pulmonary veins, and by the trunk of the bronchia, there is a pretty broad ligament, which ties the posterior edge of each lung to the lateral parts of the vertebræ of the back from the root all the way to the diaphragm.

Trachea arteria. The bronchia, already described, are branches or ramifications of a large canal, partly cartilaginous, and partly membranous, called trachea, or aspera arteria. It is situated anteriorly in the lower part of the neck, whence it runs down into the thorax between the two pleuræ through the upper space left between the duplicature of the mediastinum, behind the thymus.

Having reached as low as the curvature of the aorta, it divides into lateral parts, one toward the right hand, the other toward the left, which enter the lungs, and are distributed through them in the manner already said. These two branches are called bronchia; and that on the right side is shorter than that of the left, whereas the right pulmonary artery is the longest.

The trachea is made up of segments of circles of cartilaginous hoops, disposed in such a manner as to form a canal, open on the back part of the cartilages, not going quite round: but this opening is filled by a soft glandular membrane, which completes the circumference of the canal; but this cannot be to give way to the œsophagus: for, instead of descending immediately upon the middle of that canal, the trachea inclines a little to the right side; and the same structure is formed in the back part of the bronchial vessels, which are at some distance from the œsophagus.

Each circle is about the twelfth part of an inch in breadth, and about a quarter of that space in thickness. Their extremities are round; and they are situated horizontally above each other, small interstices being left between them, and the lower edge of the superior segments being turned toward the upper edge of those next below them.

They are all connected by a very strong elastic membranous ligament fixed to their edges.

The trachea is covered externally with a quantity of cellular substance, which unites it to the neighbouring parts, and it is lined on the inside by a particular membrane; which appears to be partly fleshy or muscular, and partly ligamentary, perforated by an infinite number of small holes, more or less imperceptible, through which a mucilaginous fluid continually passes, to defend the inner surface of the trachea against the acrimony of the air which we breathe.

This fluid comes from small glandular bodies dispersed through the substance of the membrane, but especially from glands something larger than the former, which lie on the outer or posterior surface of that strong membrane by which the circumference of the canal is completed. The same structure is observable in the ramifications of the trachea, from the greatest to the smallest.

All the vessels of which the lungs are chiefly composed, that is, the air vessels or bronchia, and the blood vessels or the pulmonary and bronchial arteries and veins, accompany each other through this viscus.

They are disposed commonly in such a manner, even to the last ramifications, as that a subordinate trunk or branch of the bronchia lies between the like trunks or branches of the pulmonary artery and vein; the bronchial vessels being immediately joined to the bronchia. In some places these three kinds of vessels touch each other in such a manner as to have a triangular space in the middle.

The bronchia are divided into a very great number of ramifications; and the last rami are the pedicles or footstalks of the small lobuli. All the lobuli are angular, oblong, broad, thin, &c. The footstalks send out other smaller membranous pedicles, which are very short, and terminate in the bronchial vesicles or cells, of which they are continuations. The subordinate trunks and rami detach a great number of these pedicles from their convex surface.

When we blow into the lungs, the bronchial cells nearest their outer surface appear like small portions of round vesicles; and from this appearance all the bronchial cells have got the name of vesicles, though they are all angular, except those which we have now mentioned.

When we examine a lung without blowing it up, we find that the cartilaginous segments of the bronchia lie so near as to be engaged in each other; and in drawing out any portion of the bronchia by two ends, these segments are parted, and the whole canal is increased in length; but it contracts again, by means of its elastic membrane, as soon as that force is taken off.

When we open lengthwise any portion of the pulmonary artery and vein in the same lung, we meet with a great number of transverse rugæ, which are destroyed when these vessels are elongated. This is an observation made by M. Helvetius.

By virtue of this structure, all the ramifications, both of the bronchia and pulmonary arteries and veins, have constantly the same direction, whether the lung be inflated or collapsed: and they contract in length without being contorted or folded. In expiration these vessels are elongated, and shortened in inspiration.

These three vessels lie in a sort of cellular vagina, which accompanies all their ramifications, and is a continuation of their interlobular cells. The pelliculæ which compose it are, however, there disposed in a more regular manner, and more longitudinally than in other places, and thereby appear to form a true vagina.

When we blow through a pipe, introduced so far as to touch immediately a trunk of the blood vessels or bronchia, the air runs through all the cells that lie nearest that trunk or its branches; but if we continue to blow, it insinuates itself through the whole interlobular substance.

Bronchial glands. At the angle of the first ramification of the trachea arteria, we find on both the fore and the back sides certain soft, roundish, glandular bodies, of a bluish or blackish colour, but reddish in a child; in size they vary from that of a field bean to that of a millet seed. Through these the lymphatic vessels of the lungs pass in their way to the thoracic duct.

The trachea has several coats, as has been already observed. The outermost or common covering surrounds that part of the trachea which lies in the thorax; but out of the thorax this first coat is derived from the aponeurotic

expansions of the muscles of the neck; and it is between this and the following covering that the glands, already mentioned, are situated.

The second is a proper coat, being a continuation of the cellular covering of the lungs; the pelliculæ of which, near the cartilaginous segments, serve them for an external pericardium. The third membrane lies on the inside, adhering closely to the same cartilages, and supplying to these the place of an internal pericardium.

The fourth membrane is that which completes the circumference of the cartilaginous circles of the trachea. It consists chiefly of two laminæ or strata, partly muscular and partly tendinous: the external or posterior lamina being made up of longitudinal fibres; and the internal or anterior of transverse fibres. The membrane is perforated by the small ducts of the above mentioned glands, which discharges a fluid when pressed; and being examined through a microscope, they appear vascular or folliculous, much like that of the stomach.

The ligaments between the cartilaginous circles are very strong and elastic, and each of them is confined to two cartilages, without communicating with any of the rest: being fixed to the edges of these cartilages much in the same manner as the intercostal muscles are inserted in the ribs.

As the bronchia penetrate into the substance of the lungs, they gradually lose their cartilages, till at last they become purely membranous; but the muscular lines of M. Morgagni appear as much, and sometimes more than before. The two planes above mentioned continue likewise to be visible; and we observe very distinctly sometimes, even without a microscope, a great many small holes in the pellicles of the lobuli, and bronchial vesicles or cells, which open from within outward.

Of the arteries in general.

The arteries are long elastic and pulsating tubes, the diameters of which decrease according to the number of branches which they give off.

The coats of the arteries are three in number: an external or cellular coat, a middle or muscular coat, and an internal or smooth membranous coat.

The use of the arteries is to convey blood from the heart through the lungs, throughout the system in general, or the heart itself.

The origin of the two great trunks from which they all arise has already been explained, and of these two all the rest are branches.

OF PARTICULAR ARTERIES.

The aorta.

The large arteries, termed aorta, open with a wide orifice from the superior and posterior side of the left ventricle of the heart. Its roots seem incorporated with the very substance of the heart; as it is not only intimately united with its internal surface, but some muscular striæ of the ventricle are also mixed with the white line, which is called tendo arteriosus, and which indicates the commencement of the artery. Some transverse fibres of the heart are united to the external part of the aorta, and cover it for a line and a half. Having left the heart, the aorta is immediately expanded; nor does it again recover its diameter till it sends off the subclavian artery of the right side.

In its ascent, it is first inflected to the right, behind and beyond the pulmonary artery; it gradually inclines itself to the left, till, having formed a transverse arch, it is seen projecting behind the lungs at the left side of the vertebræ. Supported by these it descends in the same straight line with themselves: till having, at last, entered the abdomen, it again begins to turn toward the right, and rests upon the middle of the vertebræ.

By the arch of the aorta is meant its parabolic flexure, the right pillar of which first stretches to the right, and then to the left, while the left advances almost in a straight line.

In considering the whole extent of the arch, we observe that it springs from the ventricle at the inferior margin of the third rib, ascends by an oblique and winding course to the lower margin of the first; its exterior and right extremity corresponding to the middle of the cartilages of the ribs; and its left extremity, being concealed by the left lobe of the lungs, proceeding onward, and in like manner corresponding to the vertebral extremity of the ribs.

FIRST SUBDIVISION.

Branches from the arch of the aorta.

I. The two coronary arteries of the heart, *viz.* the right or inferior, and left or superior, which being sent off above the interior and posterior semilunar valves, form, in returning to the heart, an acute angle with the rising trunk. II. The innominata. III. The left common carotid. IV. The left subclavian.

The three last arise at distinct branches from the greatest convexity of the arch. The first of them passes obliquely upward, and to the right over the trachea; and having advanced about two inches, divides at its right extremity into the right common carotid, and the right subclavian. The other two branch out from the aorta near the former, and are also similar to them.

I. The right coronary is larger than the left. Covered with fat, it runs between the auricle and ventricle to the flat surface and apex of the heart, inosculating freely with the left coronary, both by its branches, and the extremity of its trunk.

II. The left coronary, after going out between the pulmonary artery and left auricle, divides into two branches.

III. The right subclavian. For the description of this and the left one, see below.

IV. The common carotid has on each side a similar distribution of its branches, though the right be a little larger than the left. It lies on the anterior surface of the vertebræ, and is united by a cellular membrane to the intercostal nerve, the par vagum beneath, and the internal jugular vein above. It thus ascends one continued trunk parallel to the trachea, as high as the superior margin of the thyroid cartilage. It there divides into branches of equal size; the anterior of which is called the external, and the posterior the internal or cerebral.

Distribution of the common carotid.

I. The external or superficial carotid. This artery has scarcely arisen, when it advances forward, and divides into eight branches variously distributed.

1. The superior thyroid, issuing near the origin of the trunk, and descending windingly to the superior margin of the thyroid gland.

2. The lingual or sublingual artery, winding above the os hyoides, forward, upward and inward, to the tongue. At its commencement, it either passes over, or is covered by, the hyo glossus; then is concealed by the genio glossus.

3. The internal maxillary, labial, angular, or facial. Concealed at its origin by the stylo hyoideus, and the tendon of the digastric. Ascends tortuously forward, through the depression of the sub-maxillary gland, and, winding over the maxilla, follows the anterior margin of the masseter; afterward branches out under the zygomatic muscles, in serpentine windings, upon the face and the sides of the mouth and of the nose.

4. The ascending pharyngeal of Haller arises from the back part of the trunk, near the lingual, or from the bifurcation of the carotid. The auricular excepted, it is the smallest of the branches. It ascends upon the long anterior rectus muscle to the foramen lacerum, through which it passes, to be lost in the dura mater.

5. Occipital artery passes transversely before the jugular vein, above the rectus lateralis, proceeding between the transverse process of the atlas and mastoid process to the back part of the neck, and ascends, in widely spreading branches, to the occiput. In its course it is covered by the digastric, the trachelo mastoid, the splenius, and the complexus; and becomes subcutaneous as it approaches the occiput.

6. The posterior auricular, or stylo mastoid, rises from the trunk in the parotid gland, above the digastric muscle, and before the styloid process, then passes transversely to the ear. As it curves behind the ear, it also inclines to the posterior part of the squamous bone, inosculating with the temporal and occipital arteries.

7. The superficial temporal. This artery, concealed at first in the parotid gland, stretches above the zygomatic arch, between the jaw and meatus auditorius, and is at last extensively ramified over the side of the head.

8. Internal maxillary. This artery, larger than the temporal, rises about the middle of the ramus of the inferior maxillary bone, before the external pterygoid; and, bending inward, forward, and downward, is concealed by the maxilla. It then rises obliquely upward and forward to the spheno maxillary fissure.

II. The internal carotid or cerebral artery. This artery, in rising to its canal, is connected before to the par vagum and intercostal nerves; and behind to the rectus anticus muscle. Sometimes it forms above the vertebræ a larger or smaller projecting curvature. In this course no branches are, in general, given off. At last it enters the foramen carotideum; and passing along this canal, undergoes many remarkable inflections. On its first entering the foramen, it proceeds upward, inward, and a little forward. It then rises from the canal forward and upward at a very obtuse angle. Having at last reached the posterior part of the sella Turcica, it bends in the cavernous sinus, so as to run in an horizontal direction to the anterior clinoid process. It here rises perpendicularly, perforates the internal surface of the dura mater, and proceeds near the bottom of the brain backward to the cerebrum.

Its most remarkable branches are,

1. The othalmic artery, rising in the angle where the carotid artery leaves the sphenoid bones near its anterior clinoid processes, and running with the nerve which accompanies and rests upon it, through the optic hole, to the orbit. Lying by the external side of the optic nerve, it passes obliquely forward over it; and reaching the internal angle of the eye above its adductor, divides it into two branches.

2. The communicating artery. This, along with the deep branch of the vertebral artery of the cerebrum, forms the circle of Willis. It proceeds straight backward and inward, near the infundibulum, where it reaches the artery already mentioned, and there seems an obtuse angled quadrangle.

3. The anterior carotid artery, or arterial callosa. The internal carotid at that place where the anterior lobe of the brain is separated from the posterior, divides into two branches of nearly equal size; of which the anterior proceeds immediately inward, and a little forward; then bends above the corpus callosum, between the hemispheres, to the posterior lobes of the brain.

4. The posterior carotid, or the artery of the fossa sylviana, enters the fossa sylvii, and gives to each numerous superficial and deep seated branches to both lobes of the brain.

Distribution of the subclavian artery and its branches.

The division of the right and left subclavian artery differs only in this respect, that the right subclavian is much larger, passes obliquely over the trachea, and sends off the common carotid. Having left this branch at the side of the trachea, it is now more properly the right subclavian; and, still continuing larger than the left, proceeds nearly in a transverse direction. The left subclavian, on the other hand, while it gradually ascends from the inclining part of the arch, passes on to its place of destination with a more rapid and extensive curvature.

These two arteries run in such a direction above the superior margin of the first rib, as to be concealed for some time by the clavicle. They then proceed with the brachial plexus, across that space lying between the first and second scalene muscles; and being covered by the flattened extremity of the clavicle and pectoral muscle, bend to the axillæ, where they take the name of axillary arteries. The branches of the subclavian arteries, and their ramuli, present so many varieties, that no description, either as to their number or their direction, can in every respect correspond with nature. In general, however, the four first branches arise before the artery sinks under the scalenus, while the rest are sent off beyond the margin of this muscle. These are,

1. The internal mammary, going off from the lower and anterior part of the trunk at the highest part of the pleura, where ascending gradually, and again bending downward to the sternum, it reaches the margin of the first rib, under which it passes; and running between the pleura and middle part of the cartilages of the ribs, descends between the internal intercostal and their sternocostal muscles, as far as the diaphragm. It then passes between the diaphragm and the ribs, and dividing into many twigs, it is lost under the rectus of the abdomen, from its origin to the third rib. It bends toward the sternum, then gradually inclines outward.

2. The inferior thyroid or anterior cervical artery, rising from the fore part of the trunk, near the mammary and vertebral arteries; and being covered by the sterno mastoid, and bent a little upward and outward, immediately divides into four principal branches; the transverse scapular, the transverse cervical, the ascending thyroid, and the thyroid branch of the thyroid.

3. The superior intercostal artery rises more externally than the vertebral, from the upper and posterior surface of the trunk, then ascends with it to the hollow, then it is formed by the anterior scalenus, the surface of the first rib, and bodies of the vertebræ. It is there suddenly reflected, and proceeds to the roots of the first and second ribs within the thorax.

4. The vertebral artery, larger than the former, rises from the superior side of the subclavian; and ascending a little backward, covered by the ganglions of the intercostal and cellular membranes, reaches the perforations of the transverse processes of the cervical vertebræ; through these it penetrates, and rising perpendicularly from the sixth or sometimes from the fifth or fourth opening, reaches the aperture of the atlas, where it bends a little outward, and having passed through, undergoes another more extensive flexion backward and inward, by which it is carried transversely in a groove between the occipital bone and the atlas, to the foramen magnum. Through this opening having at last entered the cranium, it proceeds upward and forward, and at the basilar apophysis, under the medulla oblongata, meets at an acute angle with the vertebral artery of the opposite side, forming the basilar artery, to be distributed to the cerebrum and cerebellum.

The basilar artery, being formed as above, occupies the depression in the middle of the tuber annular, and at its anterior part divides into four parallel branches, proceeding from the trunk at right angles. Of these the posterior go to the cerebellum, and the two anterior, ramified on the cerebrum, unite with communicating arteries of the carotid, and form the great circle of Willis.

5. The deep or posterior cervical artery, irregular in its origin, size, and extent, and like the superficial cervical or transverse scapula of the thyroid, spreads sometimes more and sometimes less extensively with its branches. We have sometimes observed it the smallest of all, and proceeding from the superior intercostal, it generally issues from the subclavian, beyond the margin of the scalenus, though sometimes sooner under this muscle. It then winds upward and backward between the deep muscles of the back and the sixth vertebræ; and is at least so dispersed among the muscles as to bestow its ultimate branches on the complexus near the occiput.

6. The superficial cervical rises about half an inch or an inch from the first scalenus at the upper and anterior side of the subclavian, where it begins to bend downward, and immediately hides itself among the brachial nerves; and spreading out afterward toward the superior costa scapula, divides into many irregular branches.

Distribution of the axillary artery.

The subclavian artery, as it bends from its first situation between the breast and scapula, to the humerus, assumes the name of axillary. Passing out under the arch of the clavicle, it is surrounded by the nerves of the brachial plexus, the veins, glands, and a quantity of fat; lies in the hollow of the axilla, between the subscapular and serratus major; and protected externally by the pectoral muscles, it soon approaches forward to the arm and interior margin of the biceps. At last, proceeding from the axilla to the inferior border of the tendon of the latissimus dorsi, it takes the name of the humeral artery. It sends off,

1. The thoracics.

2. The inferior scapular, or infrascapular, or subscapular, rising in the inferior margin of the subscapular muscle, divided into conspicuous branches, which run in various directions.

3. The posterior circumflex artery, issuing between the subscapular and teres major; it sinks between them, winds round the neck of the humerus, under the long extensor, and afterward bends transversely under the deltoid, backward and outward from the inner side of the arm. It sometimes gives rise to the anterior circumflex, and the deep branch of the humerus or humeral profunda.

4. The anterior circumflex artery, of smaller size, sent out near the former, above the teres major, proceeds round the humerus, under the biceps and coraco brachial to the outer part of the arm, where it either disappears under the deltoid, or enters this muscle.

Distribution of the brachial or humeral artery.

The axillary artery is first known by the name of the humeral or brachial, where it proceeds from the axilla to the internal side of the arm. Having left the cavity of the axilla, and passed to the internal surface of the tendon of the teres major, it continues its course above the internal brachial to the inner side of the biceps, and gradually runs along the middle of the arm to the anterior surface of its extremity; where at last, concealed under the aponeurosis of the biceps, it divides near the bend of the fore arm into the ulnar and radial arteries.

1. The deep branch of the humerus, the large collateral, or large humeral profunda, sometimes double, rising from the inner side of the trunk, at the inferior margin of the teres major; but sometimes sooner, from the inferior scapular, or posterior circumflex.

It proceeds backward with a gentle curve; and, accompanying the extensor, runs to the cavity between the anconei muscles, where, in the passage of the spiral nerve, it divides into two branches, at the upper junction of the external anconeus and internal brachial.

2. The large anastomatic, rising sometimes double from the internal side of the trunk, a few inches above the joint; but immediately dividing, it passes in a transverse course upon the surface of the internal brachial to the flexor condyles, where, perforating the intermuscular ligament, it runs upward to the cavity, between the condyle and olecranon, covered by the tendon of the biceps and the ulnar flexor of the carpus.

The ulnar artery. The humeral artery sometimes undergoes the division already mentioned at the middle of the humerus, or even higher. This, however, is the largest artery which arises from the trunk at the bend of the arm. Scarcely has it arisen, when it sinks deep into the cavity that is occupied by the tendon of the biceps, the nerve, blood vessels, and fat. It then bends near the interstice of the bones, under the pronator teres, radial flexor, palmaris longus, and sublimis, to the lunar side of the

fore arm, proceeding gradually with many deflections between the sublimis, the profundis, and ulnar flexor, to the wrist. Passing over the wrist, it forms the superficial arch of the hand, which gives beautiful arteries to the fingers, and finally inosculates at the palm with the radical. The chief branch is,

1. The common interosseal, rising at the higher extremity of the profundus, running on the interosseous ligament, between the flexor pollicis and profundus, toward the pronator quadratus.

The radial artery, the smallest of the two branches which proceed from the division of the humeral. It runs down in a straight line upon the surface of the pronator, and gradually inclines toward the radius, between the long supinator and radial flexus, resting on the flexor of the thumb. At the lower extremity of the radius, where it is easily felt between the styliform process and the trapezium, on the back of the hand, it bends under the abductor and extensor of the thumb, near the first radial extensor; then penetrating the abductor, or semi-interosseus of the fore finger, between the metacarpal bone of the fore finger and thumb, bends, while there concealed, to the palm between the fibres of the adductor pollicis, and forms, in the hollow of the hand, under the flexors, and above the interosseous muscles, the deep volar arch, in which it terminates.

SECOND SUBDIVISION.

Branches from the descending aorta.

It appears, from the general description of the aorta, that, after the formation of the arch, it bends gradually behind the lungs to the left side of the vertebral column; and lying close upon this column, penetrates, in a straight line, behind the pleura, through the cavity of the thorax, to the muscular crura of the diaphragm, directing its course in the abdomen to the inferior lumbar vertebræ.

Anatomists have therefore properly divided the descending aorta into the thoracic and ventral, whose limits are defined by the diaphragm, which allows, by the separation of its crura, a convenient passage for the descending trunk.

Distribution of the thoracic aorta.

Through its whole descent, the thoracic aorta inclines to the left; though near the lesser or inferior diaphragm it seems gradually to approach the middle of the vertebræ. The numerous branches which it sends out, though not large, are yet worthy of notice. These are, the pericardiac, bronchial, œsophageal, and aorta, or inferior intercostal arteries.

Distribution of the ventral aorta.

The ventral or abdominal aorta, is the lowest part of the common trunk. It passes from the thorax, through the inferior muscle of the diaphragm, to the right side of the œsophagus, in a straight direction, inclining rather to the left, and proceeds gradually through the abdomen upon the surface of the vertebral column to the fifth lumbar vertebra, and to the thick ligament connecting the fourth and fifth. The inner or long crura of the diaphragm, variously interwoven behind the œsophagus, separate anteriorly on the aorta, allowing a passage through which it descends, resting posteriorly on the vertebral column. This passage is considerably larger than the trunk, loose cellular substances, connecting the pleura and peritoneum, being interposed. The aorta at this place is separated from the vena cava by the left lobe of the liver, a part of the diaphragm, and a large quantity of cellular substance; but in the space between the kidneys and the liver, these two vessels approach so near, that the margin of the artery is partly covered by the vein that afterward sends some of its branches anteriorly across.

The ventral aorta is divided at the vertebra mentioned above, into two branches of equal size, forming an acute angle as they run forward to the brim of the pelvis. These anatomists have called ilia communes, or common iliacs. The branches of the ventral aorta are best described in the order in which they occur.

1. The phrenic artery, right and left, very irregular in origin and division. Sometimes a single trunk arising above the cœliac, divides into the right and left phrenic: sometimes, again, and indeed most frequently, the right rises from the cœliac, and the left from the aorta; while, at other times, they have been observed rising together, both from the cœliac, or both from the aorta. Sometimes the single trunk or common phrenic, being larger than usual, constitutes the fourth branch of the cœliac; and then forms the superior coronary branch of the stomach. There are sometimes three or four phrenic arteries, which, as soon as they arise, tend obliquely outward before the crura of the diaphragm to the inferior margin of its tendinous alæ; and, while they here wind tortuously under the fleshy fibres, distribute various twigs, upward, outward, inward, and downward. Bending at last to the external margin of the tendon, and passing between the muscular layers, they run forward, and inosculate, upon the costal muscles, with the thoracic vessels and the artery of the opposite side. At the bend of the artery, however, they send a large branch to the posterior and inferior portion of the diaphragm, as it rises from the ribs.

II. The cœliac artery, short, but of large diameter, rising between the aorta of the diaphragm, above the eleventh dorsal vertebra, from the anterior part of the aorta, and at the superior margin of the pancreas, between the papillary lobule, or lobule of Spigelius, and the left side of the lesser arch of the stomach. It then descends in a tortuous manner forward, and to the right, and running about the third of an inch, ultimately separates into three branches in such a manner, that the two on the right seem to arise from the common base; while the left is more distinct at its origin. These are,

1. The superior coronary, or great left gastric, or superior or left gastro hepatic, smaller than the other branches, if reflected only to the stomach; but almost equal in size to the splenic, if, as sometimes happens, it sends a branch also to the liver. It appears sometimes to issue from the splenic, ascends to the left, and forward to the cardia and lesser arch of the stomach; then bending downward and to the right, reaches the margin of the stomach, where it distributes extensively its circuitous branches, forming a corona to both sides of the stomach.

2. The hepatic. This artery, which in adults is smaller than the splenic, but in children larger, rises from the right side of the cœliac, or, as sometimes happens, from the superior mesenteric, when, turning upward near the outer point of the lobule of Spigelius, it is concealed by

the pancreas; then proceeding forward, upward, and to the right, behind the right extremity of the stomach and duodenum, it observes the same obliquity as the lesser arch; and after running an inch or an inch and a half, divides below the neck of the gall bladder into the right transverse and left ascending hepatics; entering at last, with the other hepatic vessels, the transverse fissure or fossa of the liver. Enclosed in the capsule of Glisson, it occupies a middle space between the biliary ducts and the vena porta.

3. The splenic. While this artery runs along the upper surface of the pancreas, and passes transversely to the depression of the spleen, it exhibits large and repeated flexions upward and downward, bending in a circular or spiral form. Approaching the substance of the spleen, it divides into many branches, which are equally tortuous; and of those that sink into the spleen, some smaller ones return through the substance of the diaphragm or stomach.

III. The superior mesenteric, the largest of the abdominal or ventral branches, rising between the crura of the diaphragm, three or four lines below the cœliac, from the anterior part of the aorta, and under the lower edge of the pancreas, proceeds between the gland and the inferior transverse flexion of the duodenum. Passing over this portion of the intestine, it bends to the right under the mesocolon, where, received near the vertebra into the folds of the mesentery, it first inclines to the left and then to the right, where the whole artery, advancing to the right ilium, assumes the form of the Roman S, with the concave side of its large curvature looking to the right. After giving off smaller branches, the trunk sends from its right side only two branches to the large intestines; but from the left it gives a greater number of branches to the smaller intestines.

These, from twelve to twenty, rise close to one another from the left convex side of the superior mesenteric, distributing ramuli to the ileum and jejunum. Of these the superior are short and slender, the middle long and thick, the inferior shortest, and the last branch of all, as observed above, inosculates with the ileo colic. Running near and parallel to each other, they first proceed transversely; then, rising between the layers of the mesentery, divide into smaller branches, which so diverge, that in whatever direction they go, they are soon after divided into two. These branches, as they meet, form various arches, from whose convex margin new parallel branches arise, which again soon dividing, inosculate with the adjacent branches, forming smaller and more numerous arches. From the convexity of these arches other branches arise, forming a third series of arches, and where the branches are longest, even the fourth or fifth series, till the last branches near the intestines, dividing into anterior and posterior, encircle these viscera, and gradually penetrating their coats, form most beautiful arborescent ramifications on the cellular membrane. These arches, by means of their twigs, not only form various inosculations among themselves, but also with the arborescent ramifications of the two surfaces. The inner intestinal coat is so covered by these branches and the veins, as to give it the appearance of being wholly vascular. The trunks of these arborescents lie on the roots of the valvulæ. The arches are polygons; and the first series larger than the rest. The lymphatic glands and coats of the vessels are surrounded with numerous and various twigs as variously described.

IV. The inferior mesenteric or left colic. This artery rises between the renal and common iliacs, from the anterior and left side of the aorta, descends behind the peritoneum to the left side of the trunk; and having reached that place where the aorta divides into two remarkable crura forming the iliacs, sends off a large branch; and after passing the iliac artery, sinks behind the rectum into the pelvis. As it here rises forward and to the right, it enters the duplicature of the meso rectum, and accompanies the intestine as far as its internal sphincter.

V. Capsular or atrabiliary, right and left. These are distinct small arteries, which, though never wanting, as they distribute many branches to the capsular gland, yet, in almost every individual, they present irregularities in number, size, or direction. They do not, like the vein, issue from one common trunk, but from various branches, coming near together nigh the seat of the gland.

VI. The renal or emulgent artery, right and left. It is unnecessary to enumerate the varieties which anatomists have observed as to the number, origin, and magnitude of this artery. It generally rises single from the side of the aorta between the superior and inferior mesenteric artery, from which it descends transversely at less than a right angle. The left, which is rather shorter than the right, and more posterior in its origin, turns, near the kidney, over its concomitant vein; while the right, which is longer, is covered by its concomitant vein. Approaching the renal depression, it divides into two or four branches, which, sinking separately before and behind the pelvis of the kidney, are again divided, and distribute their spreading branches to the papillary ones. These, as they encircle the convex margin of the papillæ, form arches with the adjoining branches, and seem to separate the cortical from the tubular substance. From the convex and concave margin of each arch rise innumerable small arteries, of which the former encircle the cortex, and with some of their branches, pass through its substance, and disappear on the fat; while the rest are chiefly dispersed and exhausted on the tubular part. Before entering the kidney, the renals give out.

VII. The spermatic artery, right and left. This artery is very slender, but, considering the smallness of its diameter, is the longest that rises from the lateral part of the aorta. It generally has its origin between the renal and mesenteric arteries, though the right and left do not always issue from the same place; the left often rising higher, and proceeding frequently from the renal or the inferior capsular. I have observed at times, two on each side. It descends from the aorta somewhat tortuously, at a very acute angle, behind the peritoneum, and passes before the vena cava on the right side. It is more tortuous in women than in men, in whom it passes through the abdominal ring. It joins its concomitant vein upon the surface of the psoas muscle. Received by the spermatic cord, it is divided, at some inches before reaching the testes, into five branches: two of which go to the head and upper extremity of the epididymis; while the rest running down to the testicle itself, penetrate the tunica albuginea, and send off new branches in every new direction; which, proceeding in a winding course, and reduced to the

inferior margin of the testes, are partly exhausted on its substance, and partly on the convolutions of the seminiferous ducts.

VIII. The lumbar arteries, right and left, five in number; issuing from the lateral and posterior part of the aorta, at nearly a right angle. The first runs transversely under the first vertebra of the loins; the fifth, between the last vertebra and os sacrum; and the rest between the vertebral intestines: while all of them, after being reflected round the spine, sink into the intervening spaces of the vertebræ. The right are longer than the left. The superior proceed in a straight line, while the inferior incline a little downward. Two sometimes arise from a single trunk, and all except the first are covered by the psoas muscle.

THIRD SUBDIVISION.

Branches from the termination of the aorta. Distribution of the common iliacs.

The common iliacs exhaust the whole of the aorta. The right iliac crosses the lower part of the vena cava, near the origin of the iliac vein. The left leans on the outside of its concomitant vein, but does not cover it. A little below, each divides into two branches: the one, named the internal iliac or hypogastric, sinks into the cavity of the pelvis; the other, called the external iliac, passes to the thigh, where it receives the name of the femoral. The sacro median, and, at times, some minute arteries, are in general the only branches of the common iliacs.

The sacro median, similar in size to the lumbar, is an azygous artery; and, rising from the bifurcation, or a little higher from the middle of the aorta, or from one of the lumbars, or sometimes from one of the common iliacs, runs down along the middle of the anterior surface of the sacrum, as far as the coccyx, where it forms with the sacro laterals, an arch whose convexity is downward.

I. The internal iliac or hypogastric, five times larger in the fetus than the external; but, after a year, only equal in size; for while the umbilical exhausts almost the whole blood of the trunk, it seems continued into this artery, forming an arch convex downward, from whose circumference the other small arteries of the pelvis are sent off. When passing the brim of the pelvis, behind the peritoneum, it lies, with a more obtuse angle, in the middle, between the ileum and sacrum; thence bending gradually downward, between the pelvis and its viscera. When the umbilical artery decays, the trunk distributes its numerous branches in directions so various, that none of them seem to follow its course. As the common pudic and ischiadic, however, run most directly downward, they have generally been considered by anatomists as its continuation. Its branches, though constant in their destination, are irregular in their origin; some being distributed to the pelvic viscera, while others run to the external and adjoining parts.

1. The sacro lateral arteries, irregular in origin and number. Sometimes only one, sometimes more, even to five, come off from the trunk, from the posterior iliac, or the ileo lumbar. If only one be present, it goes down, near the foramina of the sacrum as far as the coccyx, and there forms the arch already mentioned. If more, the superior inosculate among themselves; while the inferior terminates in the sacro median.

2. The obturator artery, rising sometimes from the epigastric branch of the external iliac, and running toward the pelvis; more frequently, issuing from the trunk of the hypogastric, the posterior iliac, the ischiadic or ileo lumbar. It runs downward and forward, connected to the bones of the pelvis by cellular membrane, following the superior edge of the obturator internus: and passing through the sinuous depression of the thyroid hole, runs to the thigh with its concomitant nerve and vein.

3. The posterior iliac, or gluteal, the largest of all the arteries, issuing from the hypogastric. It rises from the back part of the trunk, soon after the sacro lateralis and obturator; passes, deeply upward and backward, to the superior edge of the pyriform muscle, till concealed by the two origins of the ischiadic nerve, it leaves the pelvis; then winding externally around the pyriformis, it distributes its branches among the gluteal muscles. Within the pelvis, it sometimes gives rise to the ileo lumbar, obturator, sacro lateralis, ischiadic, and common pudic.

4. The ischiadic, smaller than the former artery, but observing the same course with the hypogastric. It passes from the pelvis, between the lower edge of the pyriformis and the levator ani, and descends under the great gluteus, parallel with the larger ischiadic ligament. We have observed the trunk divide into two, sending off the middle hæmorrhoidal and pudic.

5. The common pudic, the pudic, circumflex, internal, middle, or external pudic; rising often from a common trunk with the ischiadic, but easily distinguished by its smaller size, by its bending more forward and inward while in the pelvis, by its passing out between the pyriformis and the posterior part of the levator ani, and by its greater distance from that extremity of the pyriformis which is attached to the sacrum.

Having passed from the cavity of the pelvis, it is concealed by the great sacrosciatic ligament, under which it runs to the spine of the ischium, and enters the space between the lesser and greater sacro sciatic ligaments. Having passed the spine, it next runs to the internal surface of the tuberosity of the ischium, where, being attached to the bone by the aponeurosis of the obturator internus, it follows the curved margin of the ischium, and bends forward to the ramus. The artery is here exhausted by two branches sent off near the transverse muscle of the perineum.

II. The external iliac, the other branch of the common iliac, after it has divided into two branches, near, or a little below, the junction of the sacrum and ileum. It observes the same oblique direction outward as the common iliac. Having passed obliquely over the inner edge of the psoas, and running behind the peritoneum, upon this muscle and the tendinous portion of the iliacus, it passes to the thigh under the Fallopian ligament, along with the vein covering it before, and the crural nerve attached to its external side. Having passed Poupart's ligament, it becomes the common femoral. The branches of this artery are,

1. The epigastric, rising at an acute angle, from the inner side of the trunk, near the external lateral margin of the abdominal ring, and the inferior part of the Fallopian

ligament. It first descends; then, being immediately reflected, proceeds inward, behind the internal and posterior surface of the spermatic cord and epigastric vein. Now rising a little higher, and resting upon the peritoneum as it lines the abdominal muscles, it passes the outer and upper commissure of the abdominal ring, and then proceeds inward under the inferior part of the transverse muscle, bending to the rectus, behind which it ascends to the umbilicus.

2. The circumflex iliac, abdominal, or small external iliac, generally smaller than the last, and sent off a little lower than the external side of the trunk; passes upward and outward, in a retrograde course, under the peritoneum; reaches the crest of the ileum; and bending, parallel to the arched circumference of this bone, proceeds between the extremity of the iliacus internus and transversalis, as also betwixt the transversalis and obliquus internus, where it is finally expended among the abdominal muscles.

Distribution of the common femoral.

The common femoral, a continuation of the external iliac, runs without the Fallopian ligament in the groin. The femoral vein under which it lies, conceals its internal margin, while the whole is covered by a large quantity of cellular substance, fat, inguinal glands, and the fascia of the thigh. Advancing about two inches, it divides on the inferior part of the iliacus internus, into two arteries of nearly equal size. Of these, the continuation of the trunk is called the superficial femoral; and that which rises from the back part of the trunk, the deep femoral or femoral profunda. From the common trunk generally arise,

I. The deep femoral concealed at its origin by the superficial femoral, the glands, and a quantity of fat, lies in the deep triangular cavity, between the iliacus, pectineus, and adductors; and bending convexly outward, over the united iliacus and psoas, runs backward and downward, to the higher extremity of the vastus internus. Having reached the bottom of the cavity, it again bends greatly forward; and passing between the long and short adductors, and the vastus internus, runs, downward and backward, near to the middle of the femur. At last, entering the space between the long and short adductors, or perforating this last muscle, it reaches the adductor magnus, and passes through it with various branches, running among the posterior muscles of the thigh. The first direction and size of the trunk vary considerably, according as it issues, sooner or later, from the common femoral, and according to the number and size of the branches which it sends off. Of these some are of little consequence; but there are some which merit attention.

1. The external circumflex, a conspicuous branch, and often the first when it arises from this artery; though it sometimes issues from the superficial femoral. It bends outward, between the iliacus internus, the rectus and sartorius, and between the tensor faciæ and the anterior surface of the middle gluteus; then passing transversely under the tendinous head of the vastus externus, disappears at last near the root of the large trochanter.

2. The internal circumflex rises near the origin of the external, from the internal and posterior part of the trunk; passes to the middle of the pectineus through the adipose substance, between this muscle and the tendon of the psoas, and runs deeply backward above the trochanter minor. Concealed here by muscles and fat, it divides into branches between the short and great adductor, or between the adductor and pectineus. Of these branches, the largest approaches the neck of the femur, acetabulum, and obturator externus, and proceeding outward and backward to the insterstice between the quadratus and adductor magnus, divides into two branches; and is partly expended on the muscles attached to the femur, and partly through the interstice to the flexus of the thigh.

3. The perforants.

II. The superior femoral artery, lying externally, and covered through its whole course by the broad facia, by the inguinal glands above, and on the middle part by the sartorius, as it runs obliquely across the femur. It then proceeds downward, inward, and backward, passing gradually from the anterior to the inner surface of the thigh, and from that to the ham or poples. At first it is separated from the deep femoral, by a quantity of fat, and by the glands; then lies upon the vastus internus, and, passing along in a declivity between the vastus internus and adductors, enters the oblique canal in the common tendon of the adductors. Having passed through this canal, it takes the name of popliteal artery, where it runs from the inner to the back part of the thigh. Before reaching the posterior part, it passes over two thirds of the femur; and though the thigh be here more slender than at the superior part, it lies more deeply concealed among the muscles.

1. The large anastomatic branch, rising from the inner surface of the trunk, at the superior margin of the tendinous canal; and, bending downward, spreads, with many serpentine ramifications, on the vastus internus, into which it sinks.

2. The several perforants.

The popliteal artery; that part of the superficial femoral which runs along the ham. Its superior part is bounded by the posterior margin of the tendon of the triceps, and its inferior by the higher extremity of the soleus muscle, under which it divides into the anterior and posterior tibial arteries. Being covered externally by the aponeurosis which surrounds the joint, it runs obliquely outward and downward, through the adipose substance, between the flexor tendons, passing into the cavity between the condyles and the heads of the gastrocnemii. As it proceeds over the joint of the knee, it lies upon the capsules and afterward on the popliteal muscle. The numerous branches to which, in this course, it gives origin, are divided into articular and muscular.

1. The anterior tibial artery, smaller than the posterior, rises anteriorly from the popliteal, at the inferior margin of the popliteal muscle, and, perforating the interoseous ligament, runs to the anterior part of the leg. It descends on the ligament, at first between the tibialis anticus and common extensor, then between the anticus and extensor longus of the great toe. In this course it lies nearer the fibula than the tibia; but gradually separating from the ligament, it turns forward and inward the further it descends; and passing over the lower extremity of the tibia and the tarsus, along with the extensor tendons, under the crucial ligament, divides between the first and second metatarsal bones into two branches; of which one, sinking between the bones to the planta of the foot, inosculates with the branches of the posterior tibial, while the

other, passing along the dorsum of the foot, runs to the great toe.

II. The posterior tibial, the other branch of the popliteal, passes down under the soleus upon the posterior surface of the flexor longus and tibialis posticus, to the lower extremity of the tibia, and is afterward inflected to the sole of the foot, behind the internal ankle. While there covered by the laciniated ligament and fat, it meets the broad extremity of the abductor pollicis, and divides into two branches: one of which passing to the great toe, is the internal plantar; the external plantar runs to the sole, between the flexor brevis and longus, and under these, still deeper, to the fifth metatarsal bone. Here returning to the great toe, by an oblique and transverse flexion under the tendons of the flexor longus, it forms the plantar arch. Its chief branch is,

1. The common fibular or peroneal, very irregular in size and in the distribution of its branches. It often equals in dimension the anterior tibial; sometimes is entirely wanting, and at other times is rather smaller than the posterior tibial. Rising near the upper part of the tibialis posticus, it descends between the muscle and the flexor pollicis, by which a little lower it is covered; and at last it touches the intercrosseous ligament. Near the inferior part of the bones, it divides into the anterior and posterior fibular.

Veins.

Veins are membranous canals, which either terminate in the vena cava superior, vena cava inferior, or vena portæ. Like the arteries, they also consist of three tunics, but they have no pulsation, collapse when divided, possess a greater diameter than the arteries, have more numerous branches, a more reticular arrangement, and run more superficially. Except the veins of the viscera and brain, these vessels also possess valves.

The veins of the external part of the head and neck are the frontal, angular, temporal, auricular, lingual, occipital, and muscular. All these terminate in the external jugular, which opens into the subclavian. The veins or sinuses of the brain, *viz.* the cavernous, circular, petrosal, occipital, longitudinal, superior, and inferior, the torcular herophili, and the lateral, on the contrary, terminate in the internal jugular, which also opens into the subclavian. The vertebral veins returning from the brain, terminate semilaterally.

The chief veins of the upper extremities are the axillary in the axilla, the brachial in the arm, and the cephalic on the outside, the median on the middle, and the basilic on the inside, of the fore arm. The cephalic and basilic veins being joined by the mediana cephalica and mediana basilica, pass up the arm.

The veins of the thorax are the internal thoracic veins, the vena azygos, which returns the blood of the intercostal veins, and the two subclavian, of which the left is longer than the right, on account of the situation of the superior cava toward the right side.

The vena portæ, which is distributed through the liver, derives its blood from the mesenteric and splenic veins.

Those of the loins and pelvis exactly correspond to the lumbar and pelvic arteries.

The veins of the lower extremities are the vena saphena major, which passes up the inside of the leg and thigh, and terminates in the groin; the vena saphena minor, which passes up the outside of the leg, and terminates in the ham; the popliteal and the crural veins, which accompany their corresponding arteries.

It must be observed that both in the leg and in the thigh, each deep seated artery is accompanied by two corresponding veins, denominated venæ sodales.

Of the eye.

The principal and most essential part in each organ, is the globe or ball of the eye; the others are partly external and partly internal. The external parts are the supercilia, or eyebrows, the palpebræ, or eyelids, the caruncula lachrymalis, and the puncta lachrymalia; and the internal parts are the muscles, fat, lachrymal gland, nerves, and blood vessels.

The globe or ball of the eye.

Composition. The globe of the eye being the most essential of all the soft parts belonging to the organ of sight, and being likewise a part which we are obliged to mention as often as we speak of the other soft parts, must be first described. It is made up of several proper parts; some of which being more or less solid, represent a kind of shell formed by the union of several membranous strata, called the coats of the globe of the eye; and the other parts being more or less fluid, and contained in particular membranous capsulæ, or in the interstices between the coats, are termed the humours of the globe of the eye. The coats of the globe of the eye are of three kinds. Some form chiefly the shell of the globe; some are additional, being fixed only to a part of the globe; and some are capsular, which contain the humours. The coats, which form the globe of the eye, are, the sclerotic, to which the convexity of the globe is owing; the cornea, which forms the anterior part of the globe; the iris, or circle, surrounding the pupil, choroides, and retina, or expansion of the optic nerve. The additional is the conjunctiva, which covers the whole fore part of the eye, and lines the eyelids. The capsular tunicæ are two, the vitreæ and crystallina.

The globe of the eye thus formed, receives from behind a pretty large pedicle, which is the continuation of the optic nerve. It is situated about the middle of the orbit, in the manner which we shall afterward see; and it is tied to it by the optic nerve, by six muscles, by the tunica conjunctiva, and by the palpebræ. The back part of the globe, the optic nerve, and muscles, are surrounded by a soft, fatty substance, which fills the rest of the bottom of the orbit. The humours are three in number: the aqueous, vitreous, and crystaline. The first is contained in a space formed in the interstices of the anterior portion of the coats. The second or vitreous humour, is contained in a particular membranous capsula, and fills above three fourths of the shell or cavity of the globe of the eye. It has been named vitreous, from its supposed resemblance to melted glass; but is really more like the white of a new laid egg. The crystaline humour is so called from its resemblance to crystal, and is often named simply the crystaline. It is rather a gummy mass than an humour, of a lenticular form, more convex on the back than on the fore side, and contained in a fine membrane called membrana or capsula crystallina.

The external parts of the eye.

The supercilia, or eyebrows, are the two ridges covered with hair, situated at the lower part of the forehead, between the top of the nose and temples.

The palpebræ are a kind of veils or curtains placed transversely above and below the anterior portion of the globe of the eye. The superior is the largest and most moveable in man.

The tarsi are thin cartilages forming the principal part of the edge of each palpebra; and they are broader at the middle than at the extremities. The broad ligaments of the tarsi are membranous elongations formed by the union of the periosteum of the orbits, and pericranium along both edges of each orbit. The lachrymal gland, the use of which till of late years was not known, is yellowish, and of the number of those called conglomerate glands. From this gland several small ducts go out, which run down almost parallel to each other, through the substance of the tunica interna or conjunctiva of the superior palpebræ, and afterward pierce it inwardly near the superior edge of the tarsus.

The flat edge of each palpebra is adorned with a row of hairs, called cilia, or the eyelashes. Those belonging to the superior palpebræ are bent upward, and longer than those of the lower palpebræ, which are bent downward.

Along the same border of the palpebræ, near the internal membrane, or toward the eye, we see a row of small holes, which may be named foramina, or puncta ciliaria. They are the orifices of the same number of small oblong glands which lie in the sulci, channels, or grooves, on the inner surface of the tarsus. Near the great and internal angle of the palpebræ lachrymales, and ductus, two small holes are very visible, commonly named puncta lachrymalia, being the orifices of two small ducts called lachrymal, which unite beyond the angle of the eye, and open a little below the upper end of a particular reservoir, termed sacculus lachrymalis. The caruncula lachrymalis is a small reddish, granulated, oblong body, situated precisely between the internal angle of the palpebræ and globe of the eye. The fold which has the name membrana semilunaris, appears most when the eye is turned toward the nose; it is shaped like a crescent, the two points of which answer to the puncta lachrymalia, and conduct the tears into the puncta.

The vessels, nerves, and muscles of the eye, are each described in their place.

Of the nose.

The parts of which the nose is composed may be derived in two different ways, *viz.* from their situation, into external and internal parts; and from their structure, into hard and soft parts.

The external parts are from the root of the nose, the arch, the back or spine of the nose, the sides of the nose or of the arch, the tip of the nose, the alæ, the external nares, and the part under the septum.

The internal parts are the internal nares, the septum narium, the circumvolutions, the chonchæ superiores, or ossa spongiosa superiora, chonchæ inferiores, the posterior openings of the internal nares, the sinus frontales, sinus maxillares, sinus sphenoidales, the ductus palatini. The firm or hard parts are mostly bony, and the rest cartilaginous, *viz.* the os frontis, os ethmoides, os sphenoides, ossa maxillaria, ossa nasi, ossa unguis, ossa palati, vomer, chonchæ inferiores, and the cartilages. To these we may add the periosteum and perichondrium, as parts belonging to the bones and cartilages.

The soft parts are the integuments, muscles, sacculus lachrymalis receiving the tears, membrana pituitaria lining all the cavity of the nose, vessels, nerves, and hairs of the nares. The bony parts have been all explained in the description of the skeleton; and therefore we need only in this place to set down the distribution and disposition thereof, for the formation of some of the principal parts. The septum is formed by the descending lamina of the os ethmoides, and by the vomer, and it is placed in the groove formed by the cristæ of the ossa maxillaria, and rising edges of the ossa palati. The fore part of the nose is formed by the ossa nasi; and the sides by the superior apophyses of the ossa maxillaria.

The internal nares, or the two cavities of the nose, comprehend the whole space between the external nares and posterior openings, immediately above the arch of the palate, whence these cavities reach upward as far as the lamina cribrosa of the os ethmoides, where they communicate forward with the sinus frontales, and backward with the sinus sphenoidales. Laterally, these cavities, are bounded on the inside by the septum narium; and on the outside, or that next the cheek, by the conchæ, or ossa spongiosa, between which they communicate with the sinus maxillares.

Of the ear.

The external ear. Two portions are distinguished in the external ear; one large and solid, called pinna, which is the superior, more cartilaginous, and by much the greater part; the other small and soft, called the lobe, which makes the lower part. We may likewise consider two sides in the outward ear, one turned obliquely forward, and irregularly concave; the other turned obliquely backward, and unequally convex.

The fore side is divided into eminences and cavities. The eminences are four in number, called helix, antihelix, tragus, and antitragus. The helix is the large folded border, or circumference of the great portion of the ear. The antihelix is the large oblong eminence, or rising, surrounded by the helix. The tragus is the small anterior protuberance below the anterior extremity of the helix, which, in an advanced age, is covered with hairs. The antitragus is the posterior tubercle, below the inferior extremity of the antihelix.

The cavities on the fore side are four in number; the hollow of the helix, the depression at the superior extremity of the antihelix, called fossa auricularis; the conchæ, or great double cavity, that lies under the rising termed antihelix, the upper bottom of which is distinguished from the lower by a continuation of the helix, in form of a transverse crista; and lastly, the meatus of the external ear, situated at the lower part of the bottom of the concha.

The other parts of the external ear are ligaments, muscles, integuments, sebaceous, and ceruminous glands, vessels, and nerves.

The bony part of the organ of hearing may be divided into four general parts. 1. The meatus auditorius externus. 2. The tympanum. 3. The labyrinth. 4. The mea-

tus auditorius internus. It may likewise be divided into immoveable or containing parts, which take in all the four already mentioned; and moveable or contained parts, which are four little bones lodged in the tympanum, called incus, malleus, stapes, and os orbiculare or lenticulare.

The meatus externus is somewhat more than half an inch in length, running obliquely from behind forward in a curved direction. It terminates inwardly by an even circular edge, which is grooved quite round, for the attachment of the membrana tympani.

The tympanum, or drum of the ear, is a cavity somewhat spherical, or rather hemispherical, the bottom of which is turned inward, and the mouth joined to the circular groove already mentioned. The remarkable eminences are three in number; a large tuberosity, lying in the very bottom of the tympanum, a little toward the back part, and a small irregular pyramid, situated above the tuberosity, and a little more backward, the apex of which is perforated by a small hole. In the third eminence is a cavity situated at the upper end, a little toward the anterior part of the bottom of the tympanum. This cavity is part of a half canal, which, in a natural state, has one of the muscles of the malleus lodged in it.

The principal cavities in the tympanum are, the opening of the mastoid cells, the opening of the Eustachian tube, the bony half canal, the fenestra ovalis and rotunda; and to these may be added the small hole in the pyramid.

The labyrinth is divided into three parts; the anterior, middle, and posterior; the middle portion is termed vestibulum, the anterior cochlea, and the posterior labyrinth in particular, which comprehends the three semicircular canals.

The cochlea lies forward and inward, toward the extremity of the pars petrosa; the semicircular canals backward and outward, toward the basis of the process, and the vestibulum between the other two.

The meatus auditorius internus, is on the back side of the pars petrosa, in some measure behind the vestibule and basis of the cochlea fossulæ; one large and the other small.

The ductus auris palatinus, or Eustachian tube, is a canal or duct, which goes from the tympanum to the posterior openings of the nares, and toward the arch of the palate.

The membrana tympani is a thin, transparent, flattish pellicle, the edge of which is round, and strongly fixed in the orbicular groove which divides the bony meatus of the external ear from the tympanum, or barrel. The whole internal cavity of the labyrinth is filled with a watery fluid, secreted from the vessels, which are dispersed upon the periosteum. This fluid transmits to the nerves the vibrations it receives from the membrane situated between the tympanum and labyrinth.

The superfluous part of this fluid is supposed to pass off through two small canals, called aqueducts of Cotunnius.

The portio mollis of the auditory nerve ends, by its trunk, at the great fossula of the internal auditory hole, whence the filaments pass through the cochlea, the vestibule, and the semicircular canals, upon membranous canals, and bags disposed within them.

Of the mouth, and organ of taste.

The mouth may be distinguished into external and internal; and the parts of which it consists may likewise come under the same two general heads. The bony parts are the ossa maxillaria, ossa palati, maxilla inferior, and the teeth; to these we may add os hyoides, and the upper vertebræ of the neck.

The external parts of the mouth are, the two lips, one upper the other under; the borders, or red part of the lips, the corners, or commissures of the lips; the fossula of the upper lip, the basis of the under lip; the chin, the basis of the chin; the skin; the beard; and even the cheeks, as being the lateral parts of the mouth in general, and of the lips in particular.

The internal parts of the mouth are, the gums, palate, septum palati, uvula, amygdalæ, the tongue, the membrane which lines the whole cavity, the salival duct and glands, and the bottom of the mouth.

The palate is that arch or cavity of the mouth, surrounded anteriorly by the alveolar edge and teeth of the upper jaw, and reaching thence to the great opening of the pharynx. The arch is partly solid and immoveable, and partly soft and moveable. The solid portion is that which is bounded by the teeth, being formed by the two ossa maxillaria, and two ossa palati. The soft portion lies behind the other, and runs backward, like a veil fixed to the edge of the ossa palati, being formed partly by the common membrane of the whole arch, and partly by several muscular fasciculi, &c.

The velum palati, terminates below by a loose floating edge, representing an arch, situated transversely above the basis, or root, of the tongue. The highest portion, or top, of this arch, sustains a small, soft, and irregularly conical glandular body, fixed by its basis to the arch, and its apex hanging down, without adhering to any thing, which is called uvula. On each side of the uvula there are two muscular half arches, called columnæ septi palati, which contain between them the glands called amygdalæ.

The tongue is divided into the basis and point, the upper and under sides, and the lateral portions, or edges. The basis is the posterior and thickest part; the point the anterior and thinnest part. The upper side is not quite flat, but a little convex, and divided into two lateral halves, by a shallow depressed line, called linea linguæ mediana. The edges are thinner than the other parts, and a little rounded, as well as the point. The lower side reaches only from the middle of the length of the tongue to the point. Three sorts of papillæ may be distinguished in the upper side of the tongue, capitalæ, semi-lenticulares, and villosæ.

Of the skin, and organ of touch.

The common integuments are divided into cuticula, rete mucosum, cutis vera, and corpus adiposum.

The outside of the skin is covered by a thin transparent insensible pellicle, closely joined to it, which is called epidermis, cuticula, or scarf skin.

Under the cuticle, we meet with a substance of a grayish colour, which has got the name of corpus cuticulare, or rete mucosum; it is of a soft, mucilaginous, and viscid nature, and fills up the interstices of the fibres running between the cutis vera and cuticula. After raising the cuticle in a negro, where it is thickest and most distinct, this substance appears of a black colour, and is composed of two layers. It is this that chiefly gives the colour to the skin, for it is black in the African, and white, brown, or yellowish, in the European.

The cutis vera, or skin, properly so called, is a substance of very large extent, made up of several kinds of fibres, closely connected together, and running in various directions, being composed of the extremities of numerous vessels and nerves.

It is not easily torn, may be elongated in all directions, and afterward recovers itself, as we see in the persons, in women with child, and in swellings; and it is thicker and more compact in some places than in others.

In different parts of the body, we meet with small glands, or follicles, of an oval form, and seated chiefly under the skin in the corpus adiposum. These are called sebaceous and miliary.

The last universal integument of the human body is the membrana adiposa, or corpus adiposum.

The nails are productions of the epidermis.

The hairs belong as much to the integuments as the nails. Their roots, or bulbs, lie toward that side of the skin which is next the membrana adiposa.

Of the brain.

This mass is divided into three particular portions; the cerebrum, or brain, properly so called, the cerebellum, and medulla oblongata. To these three parts, contained within the cranium, a fourth is added, which fills the great canal of the spina dorsi, by the name of medulla spinalis, being a continuation of the medulla oblongata.

The meninges, or membranes of the brain, are two in number; one of which is very strong, and lies contiguous to the cranium; the other is very thin, and immediately touches the brain. The first is named dura mater, the second pia mater. The last is again divided into two, the external lamina being termed arachnoides, the internal retaining the common name of pia mater. From the former are the falx tentorium, &c. which are septa of the brain, while the latter more immediately invest the cerebral mass.

Cerebrum.

Situation and figure. The cerebrum, properly so called, is a kind of medullary mass, of a moderate consistence, and of a grayish colour on the outer surface, filling all the superior portion of the cavity of the cranium; or that portion which lies above the transverse septum. The upper part of the cerebrum is of an oval figure. It is flatter on the lower part, each lateral half of which is divided into three eminences, which correspond with the cavities at the base of the cranium.

Division and lobes. The cerebrum is divided into two lateral portions, separated by the falx, or great longitudinal septum of the dura mater. They are generally termed hemispheres, but they are more like quarters of an oblong spheroid. Each of these portions is divided into two extremities, one anterior, and one posterior, which are termed the lobes of the cerebrum, between which there is a large inferior protuberance, which goes by the same name; so that in each hemisphere there are three lobes, one anterior, one middle, and one posterior. The anterior and middle lobes of the cerebrum on each side are parted by a deep narrow sulcus, termed fissura magna sylvii.

Sides and inequalities. Each lateral portion of the cerebrum has three sides, one superior, which is convex, one inferior, which is uneven, and one lateral, which is flat, and turned to the falx. Through the whole surface of these three sides, we see inequalities, or windings, like the circumvolutions of intestines, formed like weaving streaks or furrows, very deep and narrow, into which the septa, or duplicatures of the pia mater, insinuate themselves, and thereby separate these circumvolutions from each other.

Near the surface of the cerebrum, these circumvolutions are at some distance from each other, representing serpentine ridges; and in the interstices between them, the superficial veins of the cerebrum are lodged.

Substance. The substance of the cerebrum is of two kinds, distinguished by two different colours, one part of it being of a grayish or ash colour, the other, which is somewhat firmer than the former, is remarkably white, but redder in the fetus. The ash coloured substance lies chiefly on the outer part of the cerebrum, like a kind of cortex, whence it has been named substantia corticalis, or cinerea. The white substance occupies the inner part, and is termed substantia medullaris, or substantia alba. This abounds in greater quantity than the other, and in many places is perforated with red arteries.

Corpus callosum. Having cut off the falx from the crista galli, and turned it backward; if we separate gently the two lateral parts or hemispheres of the cerebrum, we see a longitudinal portion of a white convex body, which is named corpus callosum. Both extremities of this medullary body terminate by a small edge, bent transversely downward.

Medullary arch and centrum ovale. The corpus callosum becomes afterward continuous on each side, with the medullary substance, which, through all the remaining parts of its extent, is entirely united with the cortical substances, and together with the corpus callosum forms a medullary arch or vault, of an oblong or oval figure. To perceive this, the whole cortical substance, together with the medullary laminæ mixed with it, must be cautiously and dexterously cut in the same direction with the convexity of the cerebrum.

Ventriculi laterales. Under this arch are two lateral cavities, much longer than they are broad, and very shallow, separated by a transparent medullary septum; of which hereafter. These cavities are generally named the lateral ventricles of the brain.

The lateral ventricles are broad, and rounded at those extremities which lie next the transparent septum. They go from before backward, contracting in breadth, and separating from each other gradually in their progress. Afterward they bend downward, and return obliquely from behind forward, in a course like the turning of a ram's horn, and terminate almost under their superior extremities, only a little more backward and outward.

At the posterior part, where they begin to bend downward, there is on each side a particular elongation, which runs backward, and terminates in a triangular pointed cavity, turned a little inward, the two points resembling horns. These ventricles are every where lined with a continuation of the pia mater.

Septum lucidum. The transparent partition, or septum lucidum, as it is commonly called, lies directly under the raphe, or suture of the corpus callosum, of which it is a continuation, and a kind of duplicature. It is made up of two medullary laminæ, more or less separated from each other by a narrow medullary cavity, sometimes filled with a serous substance.

Fornix. The septum lucidum is united by its lower part, to the anterior portion of the particular medullary body, called improperly the fornix with three pillars. It is in reality nothing but the corpus callosum; the lower side of which is like a hollow ceiling, with three angles, one anterior, and two posterior, and three edges, two lateral, and one posterior. The lateral edges are terminated each by a large semi-cylindrical border, like two arches, which, uniting at the anterior angle, form by their union what is called the anterior pillar of the fornix; and as they run backward separately toward the two posterior angles, they have then the name of the posterior pillars.

The anterior pillar being double, is larger than either of the posterior; and the marks of this duplicity always remain. Immediately below the basis of this pillar we observe a large, white, short medullary rope, stretched transversely between the two hemispheres, and commonly called the anterior commissure, of the cerebrum. It is to this pillar that the septum lucidum adheres. The posterior pillars are bent downward, and continue through the lower portions of the ventricles all the way to their cavities, resembling a ram's horn, which is a name that has been given to them. They diminish gradually in thickness during this course, and at their outsides have each a small, thin, flat, collateral border, to which the name of corpora fimbriata is applied.

The posterior pillars of the crura of the fornix unite with two medullary protuberances, called pedes hippocampi. The inferior surface of the triangular ceiling, which lies between these arches, is full of transverse, prominent, medullary lines; for which reason the ancients called it psalloides and lyra, comparing it to a stringed instrument, something like what is now called a dulcimer.

Under the fornix, and immediately behind its anterior crura, there is a hole, the foramen Monroi, of a considerable size, by which the two lateral ventricles communicate, and another passage leads down from this under the different appellations of foramen commune anterius, vulva, iter ad infundibulum, but more properly iter ad tertium ventriculum.

Eminences. The fornix being cut off, and inverted, or quite removed, we see first of all a vascular web, called plexus choroides, and several eminences more or less covered by the expansion of that plexus. There are four pairs of eminences, which follow each other very regularly, two large, and two small. The first two great eminences are named corpora striata, and the second thalami nervorum opticorum. The four small eminences are closely united together; the anterior being called nates, and the posterior testes; but it would be better to call them simply anterior and posterior tubercles. Immediately before these tubercles, there is a single eminence, called glandula pinealis.

Corpora striata. The corpora striata got that name, because, by cutting them with the knife, we meet with a great number of white and ash coloured lines, alternately disposed, which are only the transverse section of the medullary and cortical laminæ, mixed together, in a vertical position, in the basis of the cerebrum, as appears evidently by incisions made from above downward. These two eminences are of a grayish colour on the surface, oblong, roundish, pyriform, and larger on the fore than on the back part, where they are narrow and bent.

They lie in the bottom of the superior cavity of the lateral ventricles, which they resemble in some measure in shape, their anterior parts being near the septum lucidum, from which they separate gradually, as they run backward, and diminish in size. They are in reality the convex bottoms of the ventricles; and it is at the lower part of the interstice, between the largest portions of them, that we observe the greatest transverse cord, termed the anterior commissure of the cerebrum, which we mentioned already in describing the anterior pillar of the fornix. This cord communicates more particularly with the bottom of the corpora striata, by a turn toward each side.

Thalami nervorum opticorum. The thalami nervorum opticorum are so named, because these nerves rise chiefly from them. They are two large eminences by the side of each other, between the posterior portions or the extremities of the corpora striata. Their figure is semi-spheroidal, and a little oval, and they are of a whitish colour on the surface, and their inner substance is partly grayish and partly white; so that in cutting them we see streaks of different colours, like those of the corpora striata.

These two eminences are closely joined together; and at their convex part they are so far united, as really to become one body; the whitish outer substance being continued uniformly over them both.

Third ventricle. Immediately under the union, or beginning of the thalami nervorum opticorum, lies a particular cavity, called the third ventricle of the cerebrum. This cavity communicates, at its upper and fore part, with the passage between the two lateral ventricles, and sends down from its under and fore part a passage through the infundibulum. It opens backward into the passage called the iter ad quartum ventriculum.

Infundibulum. Between the basis of the anterior pillar of the fornix, and the anterior part of the union of the optic thalami, lies a small medullary canal, named infundibulum. It runs down toward the basis of the cerebrum, contracting gradually, and terminates in a straight course by a small membranous canal, in a softish body, situated in the sella Turcica, named glandula pituitaria.

Plexus choroides. The plexus choroides is a very fine vascular texture, consisting of a great number of arterial and venal ramifications, partly collected in two loose vasculi, which lie on each lateral ventricle, and partly expanded over the neighbouring parts, and covering in a particular manner the thalami nervorum opticorum, glandula pinealis, tubercula, quadrigemina, and the other adjacent parts, both of the cerebrum and cerebellum, to all which it adheres.

Glandula pituitaria. The pituitary gland is a small spongy body, lodged in the sella Turcica, between the sphenoidal folds of the dura mater. On the outside it is partly grayish, and partly reddish, and white within. It is transversely oval or oblong; and on the lower part, in some subjects, is divided by a small notch in two lobes, like a kidney bean. It is covered by the pia mater, as by a bag, the opening of which is the extremity of the infundibulum: and is surrounded by the small circular sinuses, which communicate with the sinus of the cavernosi.

Tubercula. The tubercles are four in number, two anterior and two posterior; adhering together, as if they made but one body, situated behind the union of the thalami nervorum opticorum. They are transversely oblong,

the anterior being a little more rounded, and broader, or larger, from before backward than the posterior. Their surface is white, and their inner substance grayish.

Directly under the place where the tubercles of one side are united to those of the other side, lies iter ad quartum ventriculum, which communicates by its anterior opening with the third ventricle, under the thalami nervorum opticorum, and by its posterior opening with the fourth ventricle, which belongs to the cerebellum.

Foramen commune posterius, where the convex parts of the two anterior tubercles join these posterior convex parts of the thalami nervorum opticorum, an interstice, or opening, is left between these four convexities, but it does not communicate with the third ventricle, for the bottom of it is shut up by the pia mater. It has got the name of anus applied to it.

Glandula pinealis. The glandula pinealis is a small, soft, grayish body, about the size of an ordinary pea, irregularly round, and sometimes of the figure of a pine apple, situated behind the thalami nervorum opticorum, above the tubercula quadrigemina. It is fixed like a small button to the lower part of the thalami, by two very white medullary peduncui, which at the gland are very near each other, but separate transversely toward the thalami. This gland is almost always found to contain a peculiar gritty substance: below the glandula pinealis there is a medullary transverse cord, called the posterior commissure of the hemispheres of the cerebrum.

Cerebellum.

Situation and figure. The cerebellum is contained under the transverse septum of the dura mater, in the under and back part of the cranium. It is broader laterally than on the fore or back sides, flatted on the upper side, and gently inclined both ways, answerable to the septum, which serves it as a kind of tent or ceiling. On the lower side it is rounder; and on the back side it is divided into two lobes, separated by the occipital septum of the dura mater.

Structure. It is made up like the cerebrum, of two substances. It has two middle eminences, called appendices vermiformes: one anterior and superior, and turned forward; the other posterior and inferior, which goes backward. There are likewise two lateral appendices, both turned outward. They are termed vermiformes, from their resemblance to a large portion of an earth worm.

Fourth ventricle. When we separate the two lateral portions or lobes, having first made a pretty deep incision, we discover first of all the posterior portion of the medulla oblongata, of which hereafter: and in the posterior surface of this portion, from the tubercula quadrigemina, all the way to the posterior notch, in the body of the cerebellum; and a little below that notch, we observe an oblong cavity, which is called the fourth ventricle; this terminates backward, like the point of a writing pen. Hence the under end of it is called calamus scriptorius. If we cut one lobe of the cerebellum vertically, from above downward, the medullary substance will appear to be dispersed in ramifications, through the cortical substance. These ramifications have been named arbor vitæ, and the two trunks, whence these different laminæ arise, are called pedunculi cerebelli.

Medulla oblongata.

The medulla oblongata is a medullary substance, situated from before backward in the middle part of the basis of the cerebrum and cerebellum, without any discontinuation between the lateral parts of both these bases.

The chief medullary productions are these; the large, or anterior branches of the medulla oblongata, which have likewise been named crura anteriora medullæ oblongatæ, and pedunculi cerebri; the transverse protuberance, called likewise processus annularis, or pons Varolii; the smaller posterior branches, called pedunculi cerebelli, or crura posteriora medullæ oblongatæ; the extremity, or cauda, of the medulla oblongata, with two pairs of tubercles; one of which is named corpora olivaria, the other corpora pyramidalia; and to all these productions we must add a production of the infundibulum, and two medullary papillæ.

Medulla spinalis.

The medulla spinalis is only an elongation of the extremity of the medullă oblongata, and it has its name from its being contained in the bony canal of the spina dorsi. It is consequently a continuation or common appendix of the cerebrum and cerebellum, as well because of the two substances of which it is composed, as because of the membranes by which it is invested.

NEUROLOGY.

Of the Nerves in general.

The continuity of the cortex with the medulla of the encephalon and spinal marrow is observable with the naked eye, and is more distinctly seen with the assistance of a microscope. In dissecting the brain and cerebellum, we see the small beginnings of the medulla proceeding from the cortex, and can trace its gradual increase by the addition of more such white substance coming from the cortex. Both these substances are very succulent; for being exposed to the air to dry, they lose more of their weight than most parts of the body do.

In several places we can observe the medulla to be composed of fibres laid at each other's sides; and it is employed in forming the white fibrous cords, which have now the name of nerves appropriated to them. Within the skull we see the nerves to be the medullary substance continued, and the spinal marrow is employed in forming all nerves.

The common opinion concerning the use of the nerves, founded on a superficial inspection of those parts, is, that the nerves are propagated from that side of the encephalon at which they go out of the skull. But it having been remarked, after a more strict enquiry, and preparing the parts by maceration in water, that the medullary fibres decussate or cross each other in some parts of the medulla, as, for example, at the corpus annulare, and beginning of the spinal marrow; and practical observations having related several examples of people whose brain was hurt on one side, while the morbid symptoms, palsy, appeared on the other side of the body, of which we have seen some instances; and experiments on brutes having confirmed these observations, it has been thought that the nerves had their rise from that side of the encephalon which is opposite to their egress from the skull. It may, however, still

be said, that this last opinion is not fully demonstrated, because a decussation in some parts is not a proof that it obtains universally; and if there are examples of palsy of the side opposite to where the lesion of the brain was, there are also others, where the injury done to the brain and the palsy were both on the same side.

The nerves are composed of a great many threads lying parallel to each other, or nearly so, at their exit from the medulla. This fibrous texture is evident at the origin of most of the nerves within the skull; and in the cauda equina of the spinal marrow, we can divide them into such small threads, that a very good eye can scarce perceive them: but these threads, when looked at with a microscope, appear each to be composed of a great number of smaller threads. How small one of these fibres of the nerve is, we know not; but when we consider that every, even the most minute, part of the body is sensible, and that this must depend upon the nerves, which, all conjoined, would not make a cord of an inch diameter, being divided into branches or filaments, to be dispersed through all these minute parts, we must be convinced that the nervous fibrils are very small. From the examination of the minimum, visible, it is demonstrated, that each fibre in the retina of the eye, or expanded optic nerve, cannot exceed the size of the 32400th part of a hair.

The medullary substance of which the nervous fibrils are composed, is very tender, and would not be able to resist such forces as the nerves are exposed to within the bones, nor even the common force of the circulating fluids, were not the pia mater and tunica arachnoides continued upon them; the former giving them firmness and strength, and the latter furnishing a cellular coat to connect the threads of the nerves, to let them lie soft and moist, and to support the vessels which go with them. It is this cellular substance that is distended, when air is forced through a blow pipe thrust into a nerve; and that makes a nerve appear all spongy, after being distended with air till it dries: the proper nervous fibrils shrivelling so in drying, that they scarce can be observed. These coats would not make the nerves strong enough to bear the stretching and pressure they are exposed to in their course to the different parts of the body; and therefore, where the nerves go out at the holes in the cranium and spine, the dura mater is generally wrapped closely round them to collect their disgregated fibres into tight firm cords; and that the tension which they may happen to be exposed to may not injure them before they have got this additional coat, it is firmly fixed to the sides of the holes in the bones through which they pass.

The nervous cords, thus composed of nervous fibrils, cellular coat, pia and dura mater, have such numerous blood vessels, that after their arteries only are injected, the whole cord is tinged of the colour of the injected liquor; and if the injection is pushed violently, the cellular substance of the nerves is at last distended with it.

A nervous cord, such as has been just now described, has very little elasticity, compared with several other parts of the body. When cut out of the body, it does not become observably shorter, while the blood vessels contract three eighths of their length.

Nerves are generally lodged in a cellular or fatty substance, and have their course in the interstices of muscles and other active organs, where they are guarded from pressure; but in several parts they are so placed, as if it was intended that they should there suffer the vibrating force of arteries, or the pressure of the contracting fibres of muscles.

The larger cords of the nerves divide into branches as they go off to the different parts; the branches being smaller than the trunk from which they come, though not proportionally so; for, as Soemmerring observes, they rather form cones with apices toward the brain, and bases toward the superficies of the body. Where the nerves separate, they generally make an acute angle.

In several places different nerves unite into one cord, which is commonly larger than any of the nerves which form it. Several nerves, particularly those which are distributed to the bowels, after such union, suddenly form a hard knot, considerably larger than all the nerves of which it is made. These knots were called corpora olivaria, and are now generally named ganglions. The ganglions have thicker coats, more numerous and larger blood vessels, than the nerves; so that they appear more red and muscular. On dissecting the ganglions, fibres are seen running longitudinally in their axes, and other fibres are derived from their sides in an oblique direction to the longitudinal ones. Commonly numerous small nerves, which conjunctly are not equal to the size of the ganglion, are sent out from it, but with a structure no way different from that of other nerves.

The nerves sent to the organs of the semen lose there their firm coats, and terminate in a pulpy substance. The optic nerves are expanded into the soft tender webs, the retinæ. The auditory nerve has scarce the consistence of mucus in the vestibulum, cochlea, and semicircular canals of each ear. The papillæ of the nose, tongue, and skin, are very soft. The nerves of muscles can likewise be traced till they seem to lose their coats by becoming very soft; from which, and what we observed of the sensatory nerves, there is reason to conclude, that the muscular nerves are also pulpy at their terminations, which we cannot indeed prosecute by dissection. It would seem necessary that the extremities of the nerves should continue in this soft flexible state in order to perform their functions right; for, in proportion as parts become rigid and firm by age, or any other cause, they lose their sensibility, and their motions are more difficultly performed.

Though the fibres in a nervous coat are firmly connected, and frequently different nerves join into one trunk, or into the same ganglion, yet the sensation of each part of the body is so very distinct, and we have so much the power of moving the muscles separately, that, if the nerves are principal agents in these two functions, we have reason to believe that there is no union, confusion, or immediate communication of the proper nervous fibrils, but that each fibre remains distinct from the origin to its termination.

Many experiments and observations concur in proving, that when nerves are compressed, cut, or any other way destroyed, the parts served by such nerves, further from the head or spine than where the injuring cause has been applied, have their sensations, motions, and nourishment, weakened or lost, while no such effects are seen in the parts nearer to the origin of those nerves; and in such experiments, where the cause impeding the nerves from exerting themselves could be removed, and the structure of the nerves not injured; as, for example, when a ligature made

upon a nerve, and stopping its influence, has been taken away; the motion and sensation of the parts soon were restored: from which it would appear, that the nerves are principal instruments in our sensations and motions; and that this influence of the nerves is not inherent in them, unless the communication between these cords and their origin is preserved.

Experiments and observations show, too, that when parts of the encephalon or spinal marrow have been irritated, compressed, or destroyed, the parts of the body, whose nerves had their origin from such affected parts of the encephalon or spinal marrow, became convulsed, paralytic, insensible, or wasted; and in such cases, where the injuring cause could be removed from the origin of the nerves, the morbid symptoms observed in the parts to which these nerves were distributed, went off upon the removal of that cause; from which it is thought reasonable to conclude, that the nerves must not only have a communication with their origin, but that the influence they have upon the parts they are distributed to, depends upon the influence which they derive from the medulla encephali and spinalis.

If such causes produce constantly such effects in us and other creatures living in nearly the same circumstances as we do, the conclusions already made must be good, notwithstanding the examples of children and other creatures being born without brains or spinal marrow, or notwithstanding that the brains of adult creatures can be much changed in their texture by diseases, and that tortoises and some other animals continue to move a considerable time after their heads are cut off. We may be ignorant of the particular circumstances requisite or necessary to the being or well being of this or that particular creature, and we may be unable to account for a great many phenomena; but we must believe our eyes in the examination of facts; and if we see constantly such consequences from such actions, we cannot but conclude the one to be the cause and the other the effect. It would be as unjust to deny the conclusions just now made, because of the seemingly preternatural phenomena mentioned at the beginning of this head, as it would be to deny the necessity of the circulation of the blood in us and most quadrupeds, because a frog can jump, or a tortoise can walk about after all the bowels of its thorax and abdomen are taken out, or because the different parts of a worm crawl after it has been cut into a great many pieces. It is therefore almost universally allowed, that the nerves are principal instruments in our sensations, motions, and nourishment; and that the influence which they have, is communicated from their origin, the encephalon and medulla spinalis. But authors are far from agreeing about the manner in which this influence is communicated, or in what way nerves act to produce their effects: some alleging that the nervous fibres are all solid cords, acting by elasticity or vibration; others maintaining that these fibres are small pipes conveying liquors, by means of which their effects are produced; and certainly very considerable objections may be made to both doctrines.

Of particular nerves.

It is generally said, that there are forty pair of nerves in all; of which ten come out from the encephalon, and the other thirty have their origin from the spinal marrow.

Of the ten pair of nerves which come from the encephalon, the first is the olfactory, which long had the name of the mamillary processes of the brain, because in the brutes, cows and sheep, which were more commonly dissected by the ancients, the anterior ventricles of the brain are extended forward upon these nerves, and adhere so firmly to them, that they seem to make the upper side of the nerves. Each of them is large where it begins to stretch out, and gradually becomes smaller as it approaches the cribriform bone.

The tender structure and sudden expansion of these nerves on such a large surface, render it impossible to trace them far, which has made some authors deny them to be nerves; but when we break the circumference of the cribriform lamella, and then gently raise it, we may see the distribution of the nerves some way on the membrane of the nose, where they form a beautiful network, which has been exquisitely delineated by Scarpa, in his treatise De Olfactu et Auditu.

The contrivance of defending these long soft nerves from being too much pressed by the anterior lobes of the brain, under which they lie, is singular; because they have not only the prominent orbitar processes of the frontal bone to support the brain on each side, with the veins going into the longitudinal sinus, and other attachments bearing it up, but there is a groove formed in each lobe of the brain itself for them to lodge in. Their splitting into so many small branches before they enter the bones of the skull is likewise peculiar to them; for generally the nerves come from the brain in disgregated filaments, and unite into cords, as they are going out at the holes of the bones. This contrivance is the best for answering the purpose they are designed for, of being the organs of smelling; for had they been expanded upon the membrane of the nose into a medullary web, such as the optic forms, it would have been too sensible to bear the impressions of such objects as are applied to the nose; and a distribution in the more common way of a cord sending off branches, would not have been equal enough for such an organ of sensation.

The second pair of nerves, the optic, rising from the thalami nervorum opticorum, make a large curve outward, and then run obliquely inward and forward till they unite at the fore part of the sella Turcica; these soon divide, and each runs obliquely forward and outward, to go out at its proper hole in the sphenoid bone, accompanied with the ocular artery to be extended to the globe of the eye, within which each is expanded into a very fine cup like web, that lines all the inside of the eye, to within a little distance of the edge of the crystaline lens, and is universally known by the name of retina.

Though the substance of this pair of nerves seems to be blended at the place where they are joined, yet observations of people whose optic nerves were not joined, and others who were blind of one eye from a fault in the optic nerve, or in those who had one of their eyes taken out, make it doubtful whether there is any such intimate union of substance; the optic nerve of the affected side only being wasted, while the other was large and plump. In many fishes indeed, the doctrine of decussation is favoured; for their optic nerves plainly cross each other, without any union at the part where they are joined in men and most quadrupeds.

Those people whose optic nerves were not joined, having neither seen objects double, nor turned their eyes dif

ferent ways, is also a plain proof, that the conjunction of the optic nerves will not serve to account for either the uniform motions of our eyes, or our seeing objects single with two eyes, though it may be one cause of the remarkable sympathy of one eye with the other in many diseases.

The retina of a recent eye without any preparation, appears a very fine web, with some blood vessels coming from its centre to be distributed on it; but after a good injection of the arteries that run in the substance of this nerve, as is common to other nerves, it is with difficulty that we can observe its nervous medullary substance. The situation of these vessels in the central part of the optic nerve, the want of medullary fibres here, and the firmness of this nerve before it is expanded at its entry into the ball of the eye, may be the reason why we do not see such bodies, or parts of bodies, whose picture falls on this central part of the retina. An inflamation in those arteries of the retina which several fevers and an ophthalmia are generally attended with, may well account for the tenderness of the eyes, and inability to bear the light, which people have in these diseases. The over distension of these vessels may likewise serve to account for the black spots observed on bright coloured bodies especially, and for that smoky fog through which all objects are seen by people in some fevers. If these vessels lose their tone, and remain preternaturally distended, no object affects our retina, though the eye externally appears sound; or this may be one cause of amaurosis or gutta serena. From a partial distension of these vessels, or paralysis of part of the retina, the central part, or the circumference, or any other part of objects, may be lost to one or both eyes.

The third rise from the anterior part of the processus annularis; and piercing the dura mater a little before and to a side of the ends of the posterior clinoid process of the sphenoid bone, run along the receptacula or cavernous sinuses, at the side of the ephippium to get out at the foramina lacera; after which each of them divides into branches, of which one, after forming a little ganglion, is distributed to the globe of the eye; the others are sent to the muscular rectus of the palpebra, and to the attollens, adductor, deprimens, and obliquus minor, muscles of the eyeball. These muscles being principal instruments in the motions of the eyelid and eyeball, this nerve has therefore got the name of the motor oculi. We have frequently observed in convulsions that the eyelids widely opened, the cornea turned upward and outward, and the eyeballs sunk in the orbit, which well described the conjunct action of the muscles which this pair of nerves serves. The distension of a considerable branch of the carotid which passes over this nerve near its origin on each side, may possibly be the reason of the heaviness in the eyelids and eyes after drinking hard or eating much.

The fourth pair, which are the smallest nerves of any, derive their origin from the back part of the base of the testes; and then making a long course on the side of the annular protuberance, enter the dura mater a little further back, and more externally, than the third pair, to run also along the receptacula, to pass out at the foramina lacera, and to be entirely spent on the musculi trochleares, or superior oblique muscles of the eyes. These muscles being employed in performing the rotary motions, and the advancement of the eyeballs forward, by which several of our passions are expressed; the nerves that serve them have got the name of pathetici. Why these small nerves should be brought so far to this muscle, when it could have been supplied easily by the motor oculi, we know not.

The fifth pair are large nerves, rising from the annular processes, where the medullary processes of the cerebellum join in the formation of that tube to enter the dura mater, near the point of the petrous process of the temporal bones; and then sinking close by the receptacula at the sides of the sella Turcica, each becomes in appearance thicker, forms a distinct ganglion, and goes out of the skull in three great branches.

The first branch of the fifth is the ophthalmic, which runs through the foramen lacerum to the orbit, having in its passage thither a connection with the sixth pair. It is afterward distributed to the ball of the eye with the third; to the nose, along with the olfactory, which the branch of the fifth that passes through the foramen orbitarium internum joins, as was already mentioned in the description of the first pair. This ophthalmic branch likewise supplies the parts at the internal canthus of the orbit, the glandula lachrymalis, fat, membranes, muscles, and teguments, of the eyelids; its longest furthest extended branch passing through the foramen superciliare of the os frontis, to be distributed to the forehead.

The small fibres which this first branch of the fifth and third pair of nerves send to the eyeball, being situated on the optic nerves, and after piercing the sclerotic coat, running along the clinoid coat, on the outside of the retina, in their course to the uvea or iris, may be a cause of the sympathy between the optic nerve and the uvea, by which we more readily acquire the habit of contracting the iris, and thereby lessen the pupil, when too strong light is excluded; and, on the contrary, enlarge the pupil when the light is too faint. This, with the sympathy which must arise from some of the nerves of the membrane of the nostrils being derived from the first branch of the fifth pair of nerves, may also be the cause why an irritation of the retina, by too strong light, may produce sneezing, as if a stimulus had been applied to the membrane of the nose itself; why pressing the internal canthus of the orbit sometimes stops sneezing; why irritation of the nose, on the other hand, causes the eyelids to shut convulsively, and makes the tears to flow plentifully; and why medicines put into the nose affect diseases of the eyes.

The second branch of the fifth pair of nerves may be called maxillaris superior, from its serving principally the parts of the upper jaw. It goes out at the round hole of the sphenoid bone, and sends immediately one branch into the channel on the top of the antrum maxillare; the membrane of which, and the upper teeth, are supplied by it in its passage. As this branch is about to go out at the foramen orbitarium externum, it sends a nerve through the substance of the os maxillare to come out at Sterno's duct, to be distributed to the fore part of the palate; and what remains of it escaping at the external orbitar hole, divides into a great many branches that supply the cheek, upper lip, and nostril. The next considerable branch of the superior maxillary nerve, after giving branches which are reflected through the sixth hole of the sphenoid bone, to join the intercostal where it is passing through the skull with the carotid artery, and the portio dura of the seventh

pair as it passes through the os petrosum, is sent into the nose by the hole common to the palate and sphenoidal bone; and the remaining part of this nerve runs in the palato maxillary canal, giving off branches to the temples and pterygoid muscles, and comes at last into the palate to be lost. Hence the ache in the teeth in the upper jaw occasions a growing pain deep seated in the bones of the face, with swelling in the eyelids, cheek, nose, and under lip; and, on the other hand, an inflammation in these parts is often attended with sharp pain in the teeth.

The third or maxillaris inferior branch of the fifth pair, going out of the oval hole of the sphenoid bone, serves the muscles of the lower jaw, and the muscles situated between the os hyoides and jaw. All the salivary glands, the amygdales, and the external ear, have branches from it: it has a large branch lost in the tongue, and sends another through the canal, in the substance of the lower jaw, to serve all the teeth there, and to come out at the hole in the fore part of the jaw, to be lost in the chin and under lip. Hence a convulsive contraction of the muscles of the lower jaw, or the mouth's being involuntarily shut, a great flow of spittle or salivation, a pain in the ear, especially in deglutition, and a swelling all about the throat, are natural consequences of a violent irritation of the nerves of the lower teeth in the toothache; and pain in the teeth and ear is as natural a consequence of angina. Perhaps the sympathy of the organs of tasting and smelling may, in some measure, depend on their both receiving nerves from the fifth pair.

The sixth pair, which is the smallest except the fourth, rises from the fore part of the corpora pyramidalia: and each entering the dura mater some way behind the posterior clinoid process of the sphenoid bone, has a long course below that membrane, and within the receptaculum at the side of the sella Turcica, where it is immersed in the blood of the receptacle. It afterward goes out at the foramen lacerum into the orbit, to serve the abductor muscle of the eye. In the passage of this nerve below the dura mater, it lies very contiguous to the internal carotid artery, and to the ophthalmic branch of the fifth pair of nerves. At the place where the sixth pair is contiguous to the carotid, a nerve either goes from each of them in an uncommon way, to wit, with the angle beyond where it rises obtuse to descend with the artery, and to form the beginning of the intercostal nerve, according to the common description; or, according to other authors, this nerve comes up from the great ganglion of the intercostal to be joined to the sixth here.

The arguments for this latter opinion are, that, according to the common doctrine, this beginning of the intercostal nerve, as it is called, would rise in a manner not ordinary in nerves. In the next place, it is observed, that the sixth pair is larger nearer to the other than it is before it comes to the place where this nerve is said to go off; and therefore it is said to be more probable that it receives an addition there, rather than gives off a branch. Lastly, it is found that, upon cutting the intercostal nerves of living animals, the eyes were plainly affected; they lost their bright water; the gum or gore, as we call it, was separated in greater quantity; the pupil was more contracted; the cartilaginous membrane, at the internal canthus, came more over the eye; and the eyeball itself was diminished.

To this it is answered, in defence of the more common doctrine, 1st, That other branches of nerves go off in a reflected way, as well as this does, supposing it to be the beginning of the intercostal; and that the reflection would rather be greater, if it is thought to come up from the intercostal to the sixth. 2d, It is denied that this nerve is in ordinary thicker at its fore than at its back part; and if it was to be the thickest nearest to the orbit, the conclusion made above could not be drawn from this appearance, because other nerves enlarge sometimes where there is no addition made to them, as in the instance already mentioned of the trunk of the fifth pair, while below the dura mater. 3dly, The experiments on living animals show, indeed, that the eyes are affected upon cutting the intercostal nerve; but not in the way which might have been expected, if the intercostal had furnished such a share of the nerve that goes to the abductor muscle of the eye: for it might have been thought that this muscle would have been so much weakened immediately upon cutting the intercostal, that its antagonist, the adductor, would have greatly prevailed over it, and have turned the eye strongly in toward the nose; which is not said to be a consequence of this experiment: so that the arguments are still equivocal; and more observations and experiments must be made before it can be determined with certainty whether the sixth pair gives or receives a branch here. In the mean time, we shall continue to speak about the origin of the intercostal with the generality of anatomists.

At this place, where the intercostal begins, the fifth pair is contiguous, and adheres to the sixth; and it is generally said, that the ophthalmic branch of the fifth gives a branch or two to the beginning of the intercostal, or receives such from it. Others deny any such communication between them; and those who affirm the communication, confess that, in some subjects, they could not see it.

The seventh or auditory pair comes out from the lateral part of the annular process, behind where the medullary process of the cerebellum is joined to that tube; and each being accompanied with a larger artery than most other nerves, enters the internal meatus auditorius, where the two large bundles of fibres, of which it appeared to consist within the skull, soon separate from each other: one of them entering by several small holes into the vestibule, cochlea, and semicircular canal, is stretched on the inner camera of the ear in a very soft pulpy substance, and being never seen in the form of a firm cord, such as the other parcel of this and most other nerves become, is called the portio mollis of the auditory nerve.

The other part of the seventh pair passes through Galen's foramen cœcum, or Fallopius's aqueduct, in its crooked passage by the side of the tympanum; in which passage a nerve sent to the lingual branch of the inferior maxillary nerve along the outside of the tuba Eustachiana, and across the cavity of the tympanum, where it has the name of chorda tympani, is commonly said to be joined to it. The very acute angle which this nerve makes with the fifth, or the sudden violent reflection it would suffer on the supposition of its coming from the fifth to the seventh, appears unusual; whereas if we suppose that it comes from the seventh to the fifth, its course would be more in the ordinary way, and the chorda tympani would

be esteemed a branch of the seventh pair going to join the fifth, the size of which is increased by this acquisition. This smaller bundle of the seventh gives branches to the muscles of the malleus, and to the dura mater, while it passes through the bony crooked canal; and at last comes out in a firm cord, named portio dura, at the end of this canal, between the styloid and mastoid processes of the temporal bone, giving immediately filaments to the little oblique muscles of the head, and to those that rise from the styloid process. It then pierces through the parotid gland, and divides into a great many branches, which are dispersed in the muscles and teguments that cover all the side of the upper part of the neck, the whole face and cranium, as far back as the temple, including a considerable part of the external ear. Its branches having thus a considerable connection with all the three branches of the fifth pair, and with the second cervical, occasions a considerable sympathy of those nerves with it. Hence in the toothache the pain is occasioned very little in the affected tooth, compared to what it is all along the side of the head and in the ear. By this communication or connection possibly too it is that a vibrating string held between one's teeth, gives a strong idea of a sound to the person who holds it, which nobody else can perceive. Perhaps too the distribution of this nerve occasions the head to be so quickly turned upon the impression of sound on our ears.

The eighth pair of nerves or par vagum rise from the lateral bases of the corpora olivaria in disgregated fibres, and as they are entering the anterior internal part of the holes common to the os occipitis and temporum, each is joined by a nerve which ascends within the dura mater from the tenth of the head, the first, second, and inferior cervical nerves: this every body knows has the name of the nervus accessorius. When the two get off the skull, the accessorius separates from the eighth, and descending obliquely outward passes through the sterno mastoideus muscle, to which it gives branches, and afterward terminates in the trapezius muscle of the scapula. In this course it is generally, more or less, joined by the second cervical nerve. Why this nerve, and several others which are distributed to muscles, are made to pierce through muscles, which they might have only passed near to, we do not know.

The large eighth pair, soon after its exit, gives nerves to the tongue, larynx, pharynx, and ganglion, of the intercostal nerve; and being disjoined from the ninth and intercostal, to which it adheres closely some way, runs straight down the neck behind the internal jugular vein, and at the external side of the carotid artery. As it is about to enter the thorax, a large nerve goes off from the eighth of each side; this branch of the right side turns round from the fore to the back part of the subclavian artery, while the branch of the left side turns round the great curve of the aorta; and both of them mounting up again at the side of the œsophagus, to which they give branches, are lost at last in the larynx. These are called the recurrent nerves. The muscles of the larynx being in a good measure supplied with nerves from the recurrent, it is to be expected that the cutting of them will greatly weaken the voice, though it will not entirely be lost, so long as the superior branches of the eighth pair are entire. Why the recurrent nerves rise so low from the eighth pair, to go round a large artery, and to have such a long course upward, we know not.

The eighth pair above, and at or near the place where the recurrent nerves go off from it, or frequently the recurrents themselves, send off small nerves to the pericardium, and to join with the branches of the intercostal that are distributed to the heart; but their size and situation are uncertain.

After these branches are sent off, the par vagum on each side descends behind the great branch of the trachea, and gives numerous filaments to the lungs, and some to the heart, in going to the œsophagus. The one of the left side running on the fore part of the œsophagus, communicates by several branches with the right one in its descent to be distributed to the stomach; the right one goes behind the œsophagus, where it splits and rejoins several times before it arrives at the stomach, to which it sends nerves; and then being joined by one or more branches from the left trunk, they run toward the cœliac artery, there to join into the great semilunar ganglion formed by the two intercostals.

From the distribution of the par vagum we may learn how tickling the fauces with a feather, or any such substance, excites a nausea and inclination to vomit; why coughing occasions vomiting, or vomiting raises a cough; why an attempt to vomit is sometimes in danger of suffocating asthmatic people; why the superior orifice of the stomach is so sensible as to be looked on as the seat of the soul by some; why people subject to distentions of the stomach have so often the sensation of balls in their breast and throat; why the globus hystericus is so often attended with a violent strangulation of the glottis.

The ninth pair of nerves comes from the inferior part of the corpora pyramidalia, to go out of the skull at their proper holes of the occipital bone. After their egress they adhere for some way to the eighth and intercostal; and then sending a branch that, in many subjects, is joined with branches of the first and second cervical nerves, to be distributed to the thyroid gland and muscles on the fore part of the trachea arteria, the ninth is lost in the muscles and substance of the tongue. Some have thought this nerve, and others have esteemed the third branch of the fifth pair of nerves, to be the proper gustatory nerve. We know no observation or experiments to prove either opinion, or to assure us that both nerves do not serve for tasting and for the motion of the tongue. May not the distribution of this nerve to the muscles below as well as above the os hyoides, contribute to their acting more uniformly in depressing the lower jaw or head?

The tenth pair rises in separate threads from the sides of the spinal marrow, to go out between the os occipitis and first vertebra of the neck. After each of them has given branches to the great ganglion of the intercostal, eighth, ninth, and first cervical nerves, it is distributed to the straight, oblique, and some of the extensor muscles of the head. Whether the name of the tenth of the head, or of the first vertebral, ought to be given to this pair of nerves, is of no such consequence as to deserve a debate, though it has some of the marks of spinal nerves; to wit, its being formed of filaments, proceeding from both the fore and back part of the medulla; and a little ganglion being formed where these filaments meet.

In the description of the sixth pair we followed the usual way of speaking among anatomists, and called that the beginning of the intercostal nerve which comes out of the skull; and shall therefore here subjoin a cursory description of this nerve, notwithstanding its much larger part is composed of nerves coming out from the spinal marrow. There is no greater incongruity in point of method to say, that the nerve we are describing receives additions from others that have not been described, than it is to repeat in the description of a great many nerves, that each of them gives branches to form a nerve which we are ignorant of; which is all the difference between describing the intercostal before or after the spinal nerves.

The branch reflected from the sixth pair, joined possibly by some filaments of the ophthalmic branch of the fifth, runs along with the internal carotid artery, through the crooked canal formed for it in the temporal bone, where the little nerve is very soft and pappy, and in several subjects divides and unites again, and is joined by one or more branches from the fifth, particularly of its superior maxillary branch, before it comes out of the skull. May not the compression of this nerve by the carotid artery, when stretched during the systole, contribute to the diastole of the heart? As soon as the nerve escapes out of the bony canal, it is connected a little way with the eighth and ninth; then separating from these, after seeming to receive additional nerves from them, it forms a large ganglion, into which branches from the tenth of the head, and from the first and second cervical, enter. From the ganglion the nerves come out again small, to run down the neck along with the carotid artery, communicating by branches with the cervical nerves, and giving nerves to the muscles that bend the head and neck. As the intercostal is about to enter the thorax it forms another ganglion, from which nerves are sent to the trachea and to the heart; those designed for the heart, joining with the branches of the eighth, and most of them passing between the two great arteries and the auricles, as the substance of that muscle. The intercostal after this consisting of two branches, one going behind, and the other running over, the fore part of the subclavian artery, forms a new ganglion where the two branches unite below the artery; and then descending along the sides of the vertebræ of the thorax, receives branches from each of the dorsal nerves; which branches appearing to come out between the ribs, have given the name of intercostal to the whole nerve. Where the addition is made to it from the fifth dorsal nerve, a branch goes off obliquely forward; which being joined by such branches from the sixth, seventh, eighth, and ninth dorsal, the anterior trunk is formed, and passes between the fibres of the appendix musculosa of the diaphragm to them, along with the other intercostal and the branches of the eighth pair, a large semilunar ganglion, situated between the cellular and superior mesenteric arteries; the roots of which are as it were involved in a sort of nervous network of this ganglion, from which a great number of very small nervous threads run out to be extended on the surface of all the branches of those two arteries, so as to be easily seen when any of the arteries are stretched, but not to be raised from them by dissection; and thus the liver, gall bladder, duodenum, pancreas, spleen, jejunum, ilium, and a large share of the colon, have their nerves sent from this great solar ganglion or plexus. May not the peristaltic motion of the intestines depend, in some measure, on the passage of the intercostal nerves through the diaphragm?

Several fibres of this ganglion, running down upon the aorta, meet with other nerves, sent from the posterior trunk of the intercostal, which continues its course along the sides of the vertebræ: they supply the glandular renales, kidneys, and testes in men, or ovaria in women; and then they form a network on the inferior mesenteric artery, where the nerves of the two sides meet, and accompany the branches of this artery to the part of the colon that lies in the left side of the belly, and to the rectum, as far down as the lower part of the pelvis.

The intercostal continuing down by the sides of the vertebræ of the loins, is joined by nerves coming from between these vertebræ, and sends nerves to the organs of generation, and others to the pelvis, being even joined with those that are sent to the inferior extremities.

The spinal nerves rise generally by a number of disgregated fibres from both the fore and back part of the medulla spinalis; and soon after form a little knot or ganglion, where they acquire strong coats, and are extended into firm cords; but the ganglion is entirely formed by the posterior bundle. They are distinguished by numbers, according to the vertebræ from between which they come out; the superior of the two bones forming the hole through which they pass, being the one from which the number is applied to each nerve. There are generally said to be thirty pair of them; seven of which come out between the vertebræ of the neck, twelve between those of the back, five between those of the loins, and six from the false vertebræ.

The first cervical pair of nerves come out between the first and second vertebræ of the neck; and having given branches to join with the tenth pair of the head, the second cervical, and intercostal, and to serve the muscles that bend the neck, it sends its largest branches backward to the extensor muscles of the head and neck; some of which piercing through these muscles, run up on the occiput to be lost in the teguments here; and many fibres of it advance so far forward as to be connected with the fibrils of the first branch of the fifth pair of the head, and of the portio dura of the auditory nerve. Hence possibly it is, that a clavus hystericus changes suddenly sometimes, from the forehead to a violent pain and spasm in the back part of the head and neck.

The second cervical is soon joined by some branches to the ninth of the head and intercostal, and to the first and third of the neck; then has a large branch that comes out at the exterior edge of the sterno mastoidens muscle, where it joins with the accessorius of the eighth pair; and is afterward distributed to the platysma myoides, teguments of the side of the neck and head, parotid gland, and external ear, being connected to the portio dura of the auditory nerve, and to the first cervical. The remainder of this second cervical is spent on the levator scapulæ and the extensors of the neck and head. Generally a large branch is here sent off to join the accessorius of the eighth pair, near the superior angle of the scapula. From the irritation of the branches of this nerve it probably is, that in an inflammation of the parotid gland, the neck is pained so far down as the clavicle, the head is drawn toward the shoulder of the affected side, and the chin is turned to the other side.

The third pair of the neck passes out between the third and fourth cervical vertebræ; having immediately a communication with the second, and sending down a branch, which, being joined by a branch from the fourth cervical, forms the phrenic nerve. This descending enters the thorax between the subclavian vein and artery; and then being received into a groove formed by it in the pericardium, it has its course along the capsula of the heart, till it is lost in the middle part of the diaphragm. The right phrenic has a straight course; but the left one is obliged to make a considerable turn outward, to go over the prominent part of the pericardium, where the point of the heart is lodged. Hence in violent palpitations of the heart, a pungent acute pain is felt near the left orifice of the stomach. The middle of the diaphragm scarce could have been supplied by any other nerve which could have had such a straight course as the phrenic has.

The other branches of the third cervical nerve are distributed to the muscles and teguments at the lower part of the neck and top of the shoulder. No wonder then that an inflammation of the liver or spleen, an abscess in the lungs adhering to the diaphragm, or any other cause capable of irritating the diaphragm, should be attended with a sharp pain on the top of the shoulder, as well as wounds, ulcers, &c. of the muscle itself. If the irritation of the muscle is very violent, it may occasion that convulsive contraction of the diaphragm which is called an hiccough.

The fourth cervical nerve, after sending off that branch which joins with the third to form the phrenic, and bestowing twigs in the muscles and glands of the neck, runs to the armpit, where it meets with the fifth, sixth, and seventh cervicals, and first dorsal, that escape in the interstices of the musculi scaleni to come at the armpit, where they join, separate, and rejoin, in a way scarcely to be rightly expressed in words; and, after giving several considerable nerves to the muscles and teguments which cover the thorax, they divide into several branches, to be distributed to all the parts of the superior extremity. Several of these branches we shall describe under particular names.

1. Scapularis runs straight to the cavitas semilunata of the upper coats of the scapula, which is a hole in the recent subject, by a ligament being extended from one angle of the bone to the other; giving nerves, in its way, to the muscles of the scapula. When it has passed this hole it supplies the supraspinatus muscle, and then descending at the anterior of the spine of the scapula, it is lost in the other muscles that lie on the dorsum of that bone.

2. Articularis sinks downward at the axilla, to get below the neck of the head of the os humeri, and to mount again at the back part of it; so that it almost surrounds the articulation, and is described in the muscles that draw the arm back, and to those that raise it up.

3. Cutaneous runs down the fore part of the arm, near the skin, to which it gives off branches; and then divides on the inside of the fore arm into several nerves which supply the teguments there, and on the palm of the hand. In opening the basilic vein of the arm, at the usual place, the same symptoms are sometimes produced as in opening the external jugular vein, and from a like cause; to wit, from hurting a branch of this cutaneus nerve with the lancet.

4. Musculo cutaneus, or perforans casseri, passes through the coraco brachialis muscle; and after supplying the biceps, flexor cubiti, and brachialis internus, passes behind the tendon of the biceps, and over the cephalic vein, to be bestowed on the teguments on the outside of the fore arm and back of the hand. This nerve is sometimes hurt in opening the cephalic vein, and causes pain and numbness for a short time.

5. Muscularis has a spinal course from the axilla, under the os humeri, and backward to the external part of that bone; supplying by the way the extensor muscles of the fore arm, to which it runs between the two brachial muscles, and within the supinator radii longus. At the upper part of the fore arm, it sends off a branch which accompanies the supinator longus, till it comes near the wrist; where it passes obliquely over the radius, to be lost in the back of the hand and fingers. The principal part of this nerve pierces through the supinator radii brevis, to serve the muscles that extend the hand and fingers, whose actions are not injured when the supinator acts. Part of this nerve seems to be lost upon the ligament of the wrist.

6. Ulnaris is extended along the inside of the arm, to give nerves to the muscles that extend the fore arm, and to the teguments of the elbow: toward the lower part of the arms it slants a little backward to come at the groove behind the internal condyle of the os humeri, through which it runs to the ulna. In its course along this bone it serves the neighbouring muscles and teguments; and as it comes near the wrist, it detaches a branch obliquely over the ulna to the back of the hand, to be lost in the convex part of the several fingers. The larger part of the nerve goes forward to the internal side of the os pisiforme of the wrist; where it sends off a branch, which sinks under the large tendons in the palm to go across to the other side of the wrist, serving the musculi lumbricales and interossei, and at last terminating in the short muscles of the thumb and fore finger. What remains of the ulnar nerve after supplying the short muscles of the little finger, divides into three branches: whereof two are extended along the sides of the sheath of the tendons of the flexors of the little finger, to furnish the concave side of that finger; the third branch is disposed in the same way upon the side of the ring finger, next to the little finger.

When we lean or press upon the internal condyle of the os humeri, the numbness and pricking we frequently feel, point out the course of this nerve. We have seen a weakness and strophy in the parts which we mentioned this nerve to be sent to, after a wound in the internal lower part of the arm.

7. Radius accompanies the humeral artery to the bending of the elbow, serving the flexor of the cubit in its way; then passing through the pronator radii teres muscle, it gives nerves to the muscles on the fore part of the fore arm, and continues its course near to the radius, bestowing branches on the circumjacent muscles. Near the wrist it sometimes gives off a nerve which is distributed to the back of the hand, and the convex part of the thumb, and several of the fingers, instead of the branch of the muscular. The large part of the nerve passing behind the annular ligament of the wrist, gives nerves to the short muscles of the thumb; and afterward sends a branch along each side of the sheath of the tendons of the flexors of the thumb, fore finger, middle finger, and one branch of the side of the ring finger, next to the middle one, to be lost on the concave side of those fingers.

Though the radial nerve passes through the pronator muscle, and the muscular nerve seems to be still more unfavourably placed within the supinator brevis; yet the action of these muscles does not seem to have any effect in hindering the influence of these nerves; for the fingers or hand can be bent while pronation is performing vigorously, and they can be extended while supination is exercised.

The manner of the going off of these nerves of the fingers, both from the ulnar and the radial, is, that a single branch is sent from the trunk to the side of the thumb and little finger furthest from the other fingers; and all the rest are supplied by a trunk of a nerve, which splits into two in some way before it comes as far as the end of the metacarpus, to run along the sides of the different fingers that are nearest to each other.

It might have been observed, that in describing the posterior branches of the ulnar and muscular nerve, we did not mention the particular fingers, to the convex part of which they are distributed. The reason for this omission is, the uncertainty of their distribution; for though sometimes these posterior branches go to the same fingers, to the concave part of which the anterior branches of the ulnar and radial are sent, yet frequently they are distributed otherwise.

The twelve dorsal nerves of each side, as soon as they escape from between the vertebræ, send a branch forward to join the intercostal, by which a communication is made among them all; and they soon likewise give branches backward to the muscles that raise the trunk of the body, their principal trunk being extended outward to come at the furrow in the lower edge of each rib; in which they run toward the anterior part of the thorax, between the internal and external intercostal muscles, giving off branches in their course to the muscles and teguments of the thorax.

The first dorsal, as was already observed, is particular in this, that it contributes to form the brachial nerves; and that the two branches of the intercostal which come down to the thorax form a considerable ganglion with it.

The sixth lower dorsal nerves give branches to the diaphragm and abdominal muscles.

The twelfth joins with the first lumbar, and bestows nerves on the musculus quadratus lumborum and iliacus internus.

May not the communications of all these nerves be one reason why the parts they serve act so uniformly and conjunctly in respiration, and conspire together in the convulsive motions of coughing, sneezing, &c?

The communications of these lower ones with the intercostals, may serve to explain the violent efforts of the abdominal muscles in a tenesmus, and in childbearing.

As the intercostal is larger in the thorax than any where else, and seems to diminish gradually as it ascends and descends, there is cause to suspect that this is the trunk from which the superior and inferior parts are sent as branches.

The five lumbar nerves on each side, communicate with the intercostal and with each other, and give branches backward to the loins.

The first communicates with the last dorsal, sends branches to the abdominal muscles, to the psoas iliacus, and to the teguments and muscles of the fore parts of the thigh; while its principal branch joins with the other nerves, to form the crural nerve.

The second lumbar nerve passes through the psoas muscle, and is distributed nearly in the same way as the former; as is also the third.

Branches of the second, third, and fourth, make up one trunk which runs along the fore part of the pelvis, and passing in the notch at the fore part of the great hole, common to the os pubis and ischium, is spent on the adductor muscles, and on the teguments on the inside of the thigh. This nerve is called the obturator or posterior crural nerve.

By uniting branches from the second, third and fourth lumbar nerves, a nerve is formed that passes along the psoas muscle, to escape with the external iliac vessels out of the abdomen, below the tendinous arcade of the external oblique muscle. This nerve which is named the anterior crural, is distributed principally to the muscles and teguments of the fore part of the thigh. A branch however of this nerve runs down the leg to the upper part of the foot, keeping near the vena saphena; in opening of which with a lancet at the ankle, the nerve is somewhat hurt, and occasions sharp pain at the time of operation, and afterward numbness.

The remainder of the fourth lumbar and the fifth, join in composing the largest nerve of the body, which is soon to be described.

Whoever attends to the course of these lumbar nerves, and of the spermatic vessels and nerves upon the psoas muscle, with the oblique passage of the ureter over that muscle, will not be surprised that when a stone is passing in this canal, or even when it is inflamed, the trunk of the body cannot be raised erect without great pain, or that the skin of the thigh becomes less sensible, and the thigh is drawn forward, and that the testicle often swells, and is drawn convulsively toward the ring of the abdominal muscles.

The sixth pair of the false vertebræ consist each of small posterior branches sent to the hips and large anterior branches.

The first, second, and third, after coming through the three upper holes of the os sacrum, join together with the fourth and fifth of the loins, to form the largest nerve of the body, which is well known by the name of schiatic or ischiatic nerve: this, after sending large nerves to the different parts of the pelvis, and to the external parts of generation and the povex, as also to the muscles of the hips, passes behind the great tuber of the os ischium, and then over the quadrigemini muscles to run down near to the bone of the thigh at its back part, giving off nerves to the neighbouring muscles and teguments some way above the ham, where it has the name of popliteus nerve, it sends off a large branch that passes over the fibula, and sinking, among the muscles on the anterior external part of the leg, runs down to the foot to be lost in the upper part of the larger toes, supplying the neighbouring muscles and teguments every where in its passage. The larger branch of the schiatic, after giving branches to the muscles and teguments above the ham and knee, and sending a large cutaneous nerve down the calf of the leg to be lost at last on the outside of the foot, and the upper part of the lesser toes, sinks below the gemellus muscle, and distributes nerves to the muscle on the back of the leg, among which it continues its course till passing behind the malleolus internal, and in the internal hollow of the os calcis, it divides into the two external and internal plantar nerves. The

internal is distributed to the toes in the same manner that the radial nerve of the hand serves the concave side of the thumb and fingers; and the external plantar is divided and distributed to the sole of the foot and toes, nearly as the ulnar nerve is in the palm of the hand, and in the concave part of the fingers.

Several branches of these nerves that serve the inferior extremities, pierce through muscles.

The fourth, which with the two following, is much smaller than the three superior, soon is lost in the vesica urinaria and intestinum rectum.

The fifth comes forward to the extremity of the os sacrum and coccygis to be distributed principally to the levatores ani.

The sixth may be considered as the termination of a substance called ligamentum denticulatum. For the uses of the various parts of the human body, see the article Physiology. See also Comparative Anatomy.

22, 22. Groins.
23. A Lymphatic gland in the groin, receiving lymphatics from the lower extremity.
24, 24. Lymphatics of the lower extremities.
25. A plexus of Lymphatics on the side of the pelvis.
26, 26. Musculi psoæ.
27. A plexus of Lymphatics, which having passed over the brim of the pelvis at (25,) and having entered the cavity of the pelvis, next ascends and passes behind the Iliac Artery to (29.)
28. Lymphatics of the left side passing over the upper part of the os sacrum, to meet those of the right side.
29. Right psoas, with a plexus of Lymphatics on its side.
31. Spaces occupied by lymphatic glands.
32. Trunk of the Lacteals.
33. The same dividing into two branches.
34. Thoracic duct.
35. Duct passing under the crus diaphragmatis, and under the right emulgent Artery.
38. Thoracic duct, passing under the curvature of the aorta, to be inserted into the left subclavian Vein.
39. A plexus of Lymphatics passing upon the trachea from the thyroid gland to the thoracic duct.

ANATROPE, a relaxation of the stomach, attended with loss of appetite, vomiting and nausea.

ANAUMACHON, among the ancients, the crime of refusing to serve in the fleet, the punishment of which was infamy.

ANCHILOPS, in medicine, a small tumour in the great angle of the eye, frequently degenerating into an abscess, or fistula lachrymalis.

ANCHOR, in maratime affairs, is a very large and heavy iron instrument, with a double hook at one end, and a ring at the other, by which it is fastened to a cable. It is cast into the bottom of the sea, or rivers, where taking its hold, it keeps ships from being drawn away by the wind, tide, or currents.

There are several kinds of anchors : 1. the sheet anchor, which is the largest, and is never used but in violent storms, to hinder the ship from being driven ashore. 2. The two bowers, which are used for ships to ride in a harbour. 3. The stream anchor. 4. The grapnel. The iron of which anchors are made, ought neither to be too soft nor too brittle. In order to give them a proper temper, it is the practice to join brittle with soft iron, and for this reason the Spanish and Swedish iron ought to be preferred.

The shank of an anchor is to be three times the length of one of its flukes, and a ship of 500 tons has her sheet anchor of 2000 weight; and so proportionably for others smaller or greater.

The anchor is said to be apeak, when the cable is perpendicular between the hawse and the anchor. An anchor is said to come home when it cannot hold the ship. An anchor is foul, when by the turning of the ship, the cable is hitched about the fluke. To shoe an anchor, is to fit boards upon the flukes, that it may hold the better in soft ground. When the anchor hangs right up and down by the ship's side, it is said to be a cock bell, upon the ship's coming to an anchor.

Riding at anchor, is the state of a vessel moored and fixed by her anchors. *Dropping an anchor*, imports the letting it down into the sea. In some cases it is necessary to drop two anchors opposite to each other ; one to keep the ship firm against the tide or flow, the other against the ebb. *Weighing anchor*, is the recovering it into the vessel in order for sailing. The anchor is ordinarily weighed by means of a windlass.

ANCHOR, in architecture, a sort of carving, something resembling an anchor. It is commonly placed as part of the enrichments of the boultins of capitals of the Tuscan, Doric, and Ionic orders, and also of the boultins of bed mouldings of the Doric, Ionic, and Corinthian cornices; anchors and eggs being carved alternately through the whole building.

ANCHORS, in heraldry, are emblems of hope, and are taken for such in a spiritual as well as in a temporal sense.

ANCHORAGE, or ANCHORING GROUND, a place where a ship may cast anchor.

The best anchoring ground is stiff clay or hard sand ; and the best place for riding at anchor, is where a ship is land locked and out of the tide.

ANCHORAGE, in law, is a duty taken of ships for the use of the port or harbour.

ANCHOVY, in ichthyology and commerce, a species of clupea, with the upper jaw longest. See CLUPEA.

The anchovy is so like the common sprat, another species of clupea, that it is no wonder this fish is often pickled and sold under its name.

The fishing for anchovies is carried on chiefly in the night time ; when a light being put on the stern of the vessels, the fish flock round, and are caught in the nets.

ANCHUSA, ALCANET, or BUGLOSS : a genus of the monogynia order, belonging to the pentandria class of plants. The calyx is a quinquepartite perianthium, oblong and persistent : the corolla is monopetalous and funnel shaped, the throat closed with scales : the stamina consist of five short filaments ; the antheræ oblong and covered : the pistillum has four germina, a filiform stylus, and obtuse stigma : there is no pericarpium, the calyx containing the seeds in its bosom : the seeds are four, oblong, gibbous, and engraven at the base. There are eight species, all of which may be propagated by seeds.

ANCHYLOSIS, in surgery, an immobility of the joints. This term is used when any joint of the body becomes, whether from external or internal causes, stiff and inflexible.

ANCISTRUM, a genus of the diandria monogynia class and order, and of the natural order of rosaceæ. The essential character is, cal. four leaved ; cor. none : stigma, many parted : drupe, dry, hispid, one celled.

There are three species, but scarcely deserving notice.

ANCLE. See TALUS in ANATOMY.

ANCON, in anatomy, the gibbous eminence, or flexure of the arm, the middle of the eminence on which we rest when we lean. See ANATOMY.

ANCONES, in architecture, the corners or coins of walls, crossbeams, or rafters. Vitruvius calls the consoles, which are a sort of shouldering pieces, by the name ancones.

ANCONY, in mineralogy, denotes a piece of iron fashioned into a flat bar, about three feet long, with a square rough knot at each end.

ANCRE'E, in heraldry, the same with anchored.

ANCYLE, in antiquity, a kind of shield which fell, as was pretended, from heaven, in the reign of Numa Pompilius; at which time, likewise, a voice was heard, declaring that Rome should be mistress of the world as long as she should preserve this holy buckler.

ANCYLE, in surgery, a distortion of the joints, caused by a settlement of the humours, or a distention of the nerves ; in which case remedies of a mollifying and relaxing nature are required.

ANCYLOGLOSSUM, a contraction of the ligaments of the tongue, hindering speech. This happens, either when the membrane which supports the tongue is naturally imperfect, or of too hard substance, or is occasioned by a preceding ulcer, and a hard cicatrix left under the tongue. It is to be cured only by manual operation by the surgeon.

ANCYLOTOMUS, a knife for loosening the tongue. It is applied also to all crooked bladed knives.

ANDABATÆ, in antiquity, a sort of gladiators, who, mounted on horseback, or in chariots, fought hoodwinked, having a helmet that covered their eyes.

ANDAMENTO, in music, the movement in giving out the subject of a fugue ; a theme, longer, and more important than a point.

ANDANTI, in music, signifies, especially in thorough basses, that the notes are to be played distinctly.

ANDIRA, a tree in the Brazils, the wood of which is well adapted for building. It is a genus of the diadelphia decandria class and order. It is scarcely known in Europe.

ANDRACHNE, in botany, the name given by Linnæus to a genus of plants, of the gynandria order, belonging to the monoecia class of plants. The characters are: the male calyx consists of five leaves; the corolla has five petals; and the stamina, which are also five in number, are inserted into the stylus: the female calyx is divided into five leaves; there is no corolla; the styli are three: and the capsule is trilocular, containing three seeds. Three species of no account.

ANDREW, or Knights of St. Andrew, an order of knights more usually called the order of the thistle.

Andrew, knights of St. is also an order instituted by Peter the Great of Muscovy, in 1698; the badge of which is a golden medal, on one side whereof is represented St. Andrew's cross, and on the other are these words: *Czar Pierre monarque de toute la Russie.*

ANDRIA, in Grecian antiquity, public entertainments first instituted by Minos of Crete, and, after his example, appointed by Lycurgus at Sparta, at which a whole city, or a tribe, assisted. They were managed with the utmost frugality, and persons of all ages were admitted, the younger sort being obliged by the lawgiver, to repair thither as to schools of temperance and sobriety.

ANDRAPODOCAPELI, were dealers in slaves in ancient times. At Athens, several places in the forum were appointed for the sale of slaves. Upon the first day of each month, the merchants brought them into the market, and exposed them to sale, while the crier, standing upon a stone erected for that purpose, called the people together.

ANDROGYNA, in botany, plants bearing male and female flowers, with stamens only, and some with pistils only on the same root: such are the cucumber and melon.

ANDROLEPSY, in Grecian antiquity, an action allowed by the Athenians, against such as protected persons guilty of murder. The relations of the deceased were empowered to seize three men in the city or house, whither the malefactor had fled, till he were either surrendered, or satisfaction made some other way for the murder.

ANDROMEDA, in astronomy, a small northern constellation, consisting of twenty-seven stars, visible to the naked eye; behind Pegasus, Cassiopeia, and Perseus.

Andromeda, in botany, the marsh cystus; a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the eighteenth order, bicornes. The characters are: the calyx is a quinquepartite perianthium, small, coloured, and persistent: the corolla is monopetalous, campanulated, and quinquefid, with reflected divisions: the stamina consist of ten subulated filaments, shorter than the corolla: the antheræ two horned and nodding: the pistillum has a roundish germen, a cylindric stylus larger than the stamina, and persistent, and an obtuse stigma: the pericarpium is a roundish five cornered capsule, with five cells and five valves; the seeds are very numerous, roundish, and glossy. There are twenty-five species, chiefly American plants and hardy. They are planted in black earth with other bog plants, and are on the whole ornamental.

ANDRONA, among the ancients, denotes a street, or public place, where people met and conversed together. It is also used for that part of churches destined for the men.

ANDROPOGON, a genus of the polygamia monoecia class and order, and of the natural order of grasses. The essential character is the same in the male as in the her. only in the former the styles are three; in the hermaph. the cal. is a glume; one flowered cor. glume, awned at both ends, except the A. nardus, which produces three, styles two, seed one.

There are thirty-five species, one deserving notice.

Andropogon nardus, which produces the Indian nard, or spikenard of the shops. The spikenard, as brought from the East Indies, is a congeries of small fibres issuing from one head, and matted close together, so as to form a bunch about the size of the finger, with some small strings at the opposite end of the head. The matted fibres, which are the parts chosen for medicinal purposes, are supposed by some to be the head or spike of the plant, by others the root: they seem rather to be the remains of the withered stalks, or ribs of the leaves: sometimes entire leaves and pieces of stalks are found among them: we likewise now and then meet with a number of these bunches issuing from one root. Spikenard has a warm, pungent, and bitterish taste; and a strong, not very agreeable smell. It is stomachic and carminative; and said to be alexipharmic, diuretic, and emmenagogue; but at present it is perhaps improperly very little employed.

ANDROSACE, in botany, a genus of plants, the flower of which consists of one saucer like petal, very wide at the mouth, and divided into five segments; and its fruit is a globose, unilocular capsule, containing a number of small oval or roundish seeds, affixed to a placenta. This genus belongs to the pentandria monogynia class of Linnæus, takes its name from the relief it was supposed to give mankind; being aperitive, and good in the gout, dropsy, and retention of urine. There are seven species, but now of little account.

ANDRYALA, in botany, a genus of plants, the flower of which is monopetalous, and the seed, which is single, oval, and crowned with down, has no other cover but the cup.

It belongs to the syngenesia polygamia class of Linnæus. Six species.

ANEE, in commerce, a measure for grain, used in some provinces of France.

At Lyons, it signifies a certain quantity of wine, which is the load an ass can carry at once. That load is fixed at eighty English quarts, wine measure.

ANEMOMETER, among mechanical philosophers, an instrument contrived for measuring the strength of the wind. See Pneumatics.

ANEMONE, wind flower: a genus of the polygamia order, belonging to the polyandria class of plants; and in the natural method ranking under the twenty-sixth order, multifiliquæ. It has its name from the Greek ανεμος, signifying the wind; because the flower is supposed not to open unless the wind blows. The characters are: there is no calyx; the corolla consists of petals of two or three orders, three in each series, oblongish: the stamina consist of numerous capillary filaments; the antheræ didymous and erect. The pistillum has numerous germina collected into a head; the styli are pointed; the stigmata obtuse: there is no pericarpium; the receptaculum is globular: the seeds

are very numerous. Of this genus there are twenty-eight species; but those valuable on account of the beauty of their flowers are the following:

1. Anemone Appenina is a native of Britain, and grows in woods. The flowers of this species are sometimes single, and sometimes double; their colours are white, blue, or violet. They appear in April.

2. Anemone Coronaria. 3. Anemone Hortensis. These two are natives of the Levant, particularly of the Archipelago islands, where the borders of the fields are covered with them of the most beautiful colours. When they grow wild, the flowers are commonly single; but by culture they are greatly improved: they become large and double, making some of the greatest ornaments of gardens. Their principal colours are red, white, purple, and blue; some of them are finely variegated with red, white, purple, and many intermediate shades of these colours.

4. Anemone Nemorosa grows wild in the woods in many parts of Britain, where it flowers in April and May. The flowers are white, purple, or reddish purple, sometimes single, and sometimes double, so that they make a pretty appearance.

The hepaticas and pulsatillas are now classed among the anemonies. All the single kinds are easily cultivated by seed, which must be sown in the spring in a wide pot or pan, and scarcely covered. The pot must stand out of the way of the sun, till the plants are strong, and they may be planted out in the autumn. The double anemonies are propagated by offsets. All the sorts are considered as among the finest ornaments of our gardens.

ANEMOSCOPE, according to Virtuvius's description, a machine showing from what point of the compass the wind blows.

This is done by means of an index moving about an upright circular plate, the index being turned by an horizontal axis, and the axis by an upright staff, at the top of which is the vane moved about by the wind.

ANETHUM, Dill, in botany, a genus of umbelliferous plants, of the digynia order, belonging to the pentandria class of plants. The essential characters are: the fruit is oval, compressed, striated; and the petals, five, are involute, entire, and very short. There are three species.

1. Anethum feniculum, or fennel; of which there are two varieties, the common and the sweet. Both sorts are cultivated in our gardens: the common is a perennial plant: the sweet fennel perishes, after it has given seed; nor do its seeds come to perfection in this climate.

2. Anethum graveolens, or dill, is an annual plant.

3. Finochio, a sallad herb. Of the first species, the fennel, both the seeds and roots are used in medicine. The seeds of both the fennels have an aromatic smell, and a moderately warm pungent taste: those of the sweet fennel are in flavour most agreeable, and have also a considerable degree of sweetness; hence our colleges have directed the use of these only. They are ranked among the hot seeds, and are undeservedly looked upon as stomachics. The whole of the genus are indeed only filthy weeds, unpleasant in the taste, and causing the breath to smell of those who are so indelicate as to eat them.

ANEURISM, or Aneurysm, in surgery, a throbbing tumour, distended with blood, and formed by a dilatation or rupture of an artery. See Surgery.

ANGARIA, in Roman antiquity, a kind of public service, imposed on the provincials, which consisted in providing horses and carriages for the conveyance of military stores, and other public burthens.

ANGEIOGRAPHY, or Angeiology, among anatomists, the description and history of the several vessels of the human body, as the arteries, veins, lymphatics, &c.

ANGEIOLOGY, the description of the vessels of the body, which are concerned in the circulation of the blood, and in absorption. See Anatomy.

ANGEL is a title given to bishops of several churches. In this sense is St. Paul understood by some authors, where he says women ought to be covered in the church, because of the angels; and thus in the Revelations, the seven stars are the angels, that is, bishops of the seven churches.

Angel, in commerce, the name of an ancient gold coin in England, of which some are still to be seen in the cabinets of the curious. It had its name from the figure of an angel, represented upon it. It was $23\frac{3}{4}$ carats fine, and weighed four pennyweights. Its value differed in different reigns. In the reign of Henry VI. it was 6s. 8d. in the 1st Henry VIII. 7s. 6d. in the 34th Henry VIII. 8s. in the 6th Edward VI. and in the succeeding reigns of Mary and Elizabeth, it was 10s.

ANGELIC *garment*, one which, among our ancestors, was put on a little before their death, that they might have the prayers of the monks.

ANGELICA, a genus of the digynia order, belonging to the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The essential characters are: the fruit is roundish, angled, solid, with reflecting styli; the corollæ are equal, and the petals incurvated. There are six species. The angelica, archangelica, sativa, or common angelica, which is cultivated in gardens for medicinal use, and likewise for a sweetmeat, grows naturally in the northern countries.

All the parts of angelica, especially the root, have a fragrant aromatic smell, and a pleasant bitterish warm taste, glowing upon the lips and palate for a long time after they have been chewed. The flavour of the seeds and leaves is very perishable, particularly that of the latter, which, on being barely dried, lose the greatest part of their taste and smell: the roots are more tenacious of their flavour: though even these lose part of it upon keeping. Angelica is one of the most elegant aromatics of European growth, though little regarded in the present practice. The root, which is the most efficacious part, is used in the aromatic tincture; and the stalks make an agreeable sweetmeat.

ANGELICS, in church history, an ancient sect of heretics, supposed by some to have gained this appellation from their excessive veneration of angels, and by others from their maintaining that the world was created by angels.

Angelics is also the name of an order of knights, instituted in 1191, by Angelus Flavius Comnenus, emperor of Constantinople.

ANGELITES, in church history, an ancient sect of heretics, whose distinguishing tenet was, that the persons of the Trinity have no distinct subsistence, but partake in common of the same divine essence.

ANGELOT, in the history of coins, a gold coin struck at Paris, while subject to the English, so called from the

representation of an angel supporting the arms of England and France.

ANGERONALIA, in antiquity, feasts celebrated at Rome in honour of Angerona, the goddess of silence and patience.

ANGINA, in medicine, a violent inflammation of the throat, otherwise called quinsy.

Angina *pectoris*, a disease so called from the seat of the disorder, and the sense of anxiety and strangling with which it is attended. See Medicine.

ANGIOSPERMIA, in the Linnæan system of botany, denotes those plants of the didynamia class, which have their seeds enclosed in a capsule, or seed vessel.

ANGLE, in geometry, the inclination of two lines meeting one another in a point, and called the legs of the angle. See Geometry.

ANGLING, among sportsmen, the art of fishing with a rod, to which are fitted a line, hook, and bait.

In angling the following rules are to be observed. 1. To place yourself so that your shadow does not at any time lie upon the water, if shallow. 2. To angle in a pond near the ford where the cattle go to drink, and in rivers, in such places as the fish you intend to angle for usually frequent; as for breams, in the deepest water; for eels, under banks; for chub, in deep shaded holes; for perch, in scowrs; for roach, in the same places; for trouts, in quick streams.

The best times for angling are from April to October; for in cold stormy weather, or bleak easterly winds, the fish will not bite. The time of the day, in the warm months, is in the morning, about nine o'clock, and in the afternoon, between three and five. In order to attract the fish to the place intended for angling, it will be proper once in four or five days to cast in some corn boiled soft, garbage, worms chopped to pieces, or grains steeped in blood, and dried; and if you fish in a stream, it will be best to cast in the grains above the hook.

The best way of angling with the fly, is down the river; and in order to make them rise freely, be sure to use such flies as you know they are naturally inclined to, and in such manner as they are accustomed to receive them.

ANGON, in the ancient military art, a kind of javelin used by the French. They darted it a considerable distance. The iron head of this weapon resembled a flower de luce. It is the opinion of some writers, that the arms of France are not flowers, but the iron point of the angon, or javelin of the ancient French.

ANGUINUM, ovum, among ancient naturalists, a fabulous kind of egg, said to be produced by the saliva of a cluster of serpents, and possessed of certain magical virtues.

This name is also given by Mercatus to the lapis scolopendrites.

ANGUIS, in zoology, the name of a genus of serpents, distinguished from the rest by having the belly and under part of the tail covered with scales, like those on the other parts of the body. The body is shorter, and more uniformly cylindric, than in the genus of the coluber, and the eyes are in general small, and the tail rather obtuse. No poisonous species of anguis has yet been discovered. There are 15 species; the most remarkable are:

Anguis bipes, or two footed snake; it is a native of the Indies, and has two short feet, with two toes, near the anus. In every scale of this species there is a brown point. 2. Anguis cerastes, a native of Egypt. 3. Anguis colubrina, an inhabitant of Egypt. 4. Anguis eryx, a native of Britain, and likewise of America, is about a span in length, and about the thickness of a man's finger. One from Aberdeenshire, described by Mr. Pennant, was fifteen inches long: the belly is of a bluish lead colour, marked with small white spots, irregularly disposed; the rest of the body of a grayish brown, with three longitudinal dusky lines; one extending from the head, along the back, to the point of the tail; the others broader, and extending the whole length of the sides. 5. Anguis fragilis, see plate, Nat. Hist. fig. 20, or Glass snake of Catesby. The skin is smooth, with small scales, closely connected. A small blow with a stick will cause the body to separate, not only at the place struck, but at two or three other places, the muscles being articulated in a singular manner quite through to the vertebra. They appear earlier in the spring than any other serpent, and are numerous in the sandy woods of Virginia and Carolina. 6. Anguis jaculus, or dart snake. Anguis laticauda, a native of Surinam. 7. Anguis lumbricalis, a native of America. 8. Anguis maculata, a native of America. 9. Anguis meleagris, is a native of the Indies. 10. Anguis platura: the head is oblong and without teeth; the body is about a foot and a half long, black above and white below. 11. Anguis quadrupes, or four footed snake. The body of this species is cylindrical, with 14 or 15 longitudinal ash coloured streaks; the teeth are extremely small; it has no ears: the feet are at a great distance from each other, very short, with five toes and small nails; but the toes are so minute, that they can hardly be numbered. It is a native of Java. 12. Anguis reticulata, a native of America. 13. Anguis scytale, a native of the Indies, is white, interspersed with brownish rings. 14. Anguis ventralis, blind worm, or slow worm, grows to about a foot in length, and to the thickness of a man's little finger; the head is small; the neck still more slender; from that part of the body grows suddenly, and continues of an equal bulk to the tail, which ends quite blunt. The colour of the back is cinerous, marked with very small lines, composed of minute black specks. It resembles the viper, in the manner of producing its young, which are put forth alive. It is frequent with us in gardens and pastures, where it lives principally under ground, feeding on worms.

ANGUIUM *lapis*, the name of a supposed stone in Germany, which is cylindric, with a cavity capable of admitting the finger; of a yellow colour, with variegations. The vulgar think it derives its origin from a serpent ant, but it is certainly made of glass, tinged with two or three colours. They were probably used for the same purposes with the anguinum ovum.

ANGURIA, the water melon, a genus of the diandria order, belonging to the monoecia class of plants, and in the natural method ranking under the 34th order, cucurbitaceæ. The essential characters are these: the male calyx is quinquefid, and the corolla quinquepetalous: the female calyx and corolla the same: the pericarpium is a pome beneath, with two cells: the seeds are numerous. Of this genus, Linnæus reckons three species, *viz.*

1. Anguria pedata; 2. Anguria trifoliata; and, 3. Anguria trilobata. Of these only one species is known in this country, by the name of Citrul. The fruit is cultivated in Spain, Portugal, Italy, and other warm countries

of Europe; as also in Africa, Asia, and America, where it is esteemed on account of its cooling quality; but in Britain it is deservedly held in little estimation.

ANGUSTICLAVIA, in Roman antiquity, a tunic embroidered with little purple studs. It was worn by the Roman knights, as the laticlavia was by the senators.

ANIMAL, in natural history, an organized and living body, which is also endowed with sensation: thus, minerals are said to grow or increase, plants to grow and live, but animals alone to have sensation.

The description, history, and classing of animals, makes not only a considerable, but the most excellent part of natural history, known by the name of zoology. Different authors have established different divisions or families of animals; but the most natural one seems to be into quadrupeds, birds, fishes, amphibious animals, insects, and animalcules, visible only by the help of a microscope.

ANIMALS, in heraldry, are much used, both as bearings and supporters.

ANIMAL *manures*, in agriculture, are all such as are formed from the decomposition of animal substances of any kind, as flesh, blood, hair, wool, bones, fat, &c. these are generally considered as more powerful in their effects, in promoting vegetation, than such as are derived from vegetable bodies.

ANIMAL *matter*, in chymistry. See CHYMISTRY.

ANIMAL *secretion*, the separation of the several fluids of the body from the blood.

ANIMAL *system* denotes the whole class of beings endowed with animal life, otherwise called the animal kingdom.

ANIMAL *fossile substances*, those found buried in the earth at various depths, and embedded among various strata: these are principally, 1, sea shells: 2, the teeth, bony palate, and bones of fishes; 3, the bones of land animals; 4, complete fish.

ANIMAL *economy*, the structure and uses of the different parts of the body.

ANIMALCULE, an animal so minute in its size, as not to be the immediate object of our senses.

Animalcules are seen only by the assistance of microscopes, and are perhaps more numerous than any other part of the animal creation; but the species, on a close examination, are found to be but few, in proportion to the number of individuals. The most obvious distinction among them is, that some have, and others have not tails; and that some have, and others have not visible limbs. According, therefore, to these characters, they are arranged under three classes, distinguished by the names of gymnia, cercaria, arthronia; the first containing those which have no visible limbs, nor any tail; the second, those which have tails; the third, those which have visible limbs.

Animalcules are discovered by the microscope in most liquors, as water, wine, vinegar, &c. in several chalybeat waters, in oats, barley, &c. and in the pustules of the itch. See MICROSCOPE,

ANIMATED POWER, in mechanics, denotes a man, or other animal, in opposition to weights, &c.

ANIMATION, suspended. See DROWNING.

ANIME, or GUM ANIMÆ, in natural history and pharmacy, a kind of gum, or rather resin, being a friable substance, inflammable, and soluble in highly rectified spirit. There are two kinds, the oriental and occidental: the oriental is a dry resin, brought in large casks, and of a very uncertain colour, some being greenish, some reddish, and some of the colour of myrrh. See HYMENÆA.

The occidental is a yellowish white, resembling frankincense in colour. Both kinds are used in perfumes, and in medicine externally.

ANIME', in heraldry, a term used when the eyes of any rapacious creature are borne of a different tincture from the creature itself.

ANIMELLÆ, the glands under the ears, called also lactiinea.

ANINGA, in commerce, a root which grows in the Antilles islands, and is pretty much like the China plant. It is used by sugar bakers for refining the sugar, and is more effectual and less dangerous than the sublimate of mercury and arsenic.

ANISE, *anisum*, in the materia medica, a small seed, of an oblong shape, ending each way in an obtuse point, with a surface very deeply striated, and of a lax and brittle substance. For the plant which produces it, see PIMPINELLA.

ANKER, a liquid measure at Amsterdam. It contains about thirty-two gallons English measure.

ANKLE. See TALUS in ANATOMY.

ANNALE, in the church of Rome, a term applied to the masses celebrated for the dead, during a whole year.

ANNALS, a species of history, which relates events in the chronological order wherein they happened.

ANNATES, or first fruits, a year's income of a spiritual living.

These were, in ancient times, given to the pope throughout all Christendom, upon the decease of any bishop, abbot, or parish clerk, and were paid by his successor. In England, the pope claimed them first of such foreigners as he conferred benefices upon, by way of provision; but afterward they were demanded of all other clerks on their admission to benefices. At the reformation they were taken from the pope, and vested in the king; and finally, queen Anne restored them to the church, by appropriating them to the augmentation of poor livings.

ANNEALING, or NEALING, as it is called by the workmen, is a process particularly employed in the glass houses, and consists in putting the glass vessels as soon as they are formed, and while they are yet hot, into a furnace or oven, not so hot as to remelt them, and in which they are suffered to cool gradually. This is found to prevent their breaking so easily as they otherwise would, and particularly on exposure to heat. There is also this difference between annealed and unannealed glass, that when the latter is broken it often flies into small powder, as is remarkably exemplified in the little glass bubbles sold in the streets, and called Prince Rupert's drops, which are drops of common bottle glass which fall from the rods on which bottles are made, into water, which suddenly cools them. See RUPERT'S DROPS. Various theories have been started to account for these phenomena, but none of them quite satisfactory, and all that can be said is, that by gradually cooling, the glass becomes perfectly chrystalized.

A similar process is used for rendering cast iron vessels less brittle, and the effect depends probably on the same principles.

ANNEXATION, in law, a term used to imply the uniting of lands or rents to the crown.

ANNONA, in Roman antiquity, denotes provision for a year of all sorts, as of flesh, wine, &c. but especially of corn.

Annona is likewise the allowance of oil, salt, bread, flesh, corn, wine, hay, and straw, which was annually provided by contractors for the maintenance of an army.

ANNONA, or Custard Apple, a genus of the polyandria polygynia class and order. The characters are: the calyx is a triphylous perianthium: the corolla consists of six heart shaped petals: the stamina have scarcely any filaments; the antheræ are numerous, sitting on the receptaculum: the pistillum has a roundish germen; no styli: the stigmata obtuse and numerous: the pericarpium is a large roundish unilocular berry, covered with a scaly bark: the seeds are numerous. There are 10 species; the most remarkable are:

1. The annona muricata, or sour sop, which rarely rises above 20 feet high: the fruit or apple is large, of an oval shape, irregular, and pointed at the top, of a greenish yellow colour, and full of small knobs on the outside: the pulp is soft, white, and of a sour and sweet taste intermixed, having many oblong, dark coloured seeds. It much resembles the black currant, and is a native of the West Indies. 2. The annona palustris, or water apple, grows to the height of 30 or 40 feet; the fruit is seldom eaten but by negroes, and the tree grows in moist places in all the West India islands. 3. The annona reticulata, or custard apple, is also a native of the West Indies, where it grows to the height of 25 feet; the fruit is of a conical form, as large as a tennis ball, of an orange colour when ripe, having a soft, sweet, yellowish pulp, of the consistence of a custard, whence it has its name. 4. The annona triloba, or North American annona, called by the inhabitants papaw, is a native of the Bahama islands, and likewise of Virginia and Carolina. The trunks of the trees are seldom bigger than the small part of a man's leg, and are about 10 or 13 feet high. The fruit grows in clusters of 3 or 4 together: when ripe, they are yellow, covered with a thin smooth skin, which contains a yellow pulp of a sweet luscious taste. All parts of the tree have a rank, if not a fetid, smell; nor is the fruit relished by many except negroes. This last sort will thrive in the open air in England, if it is placed in a warm and sheltered situation; but the plants should be trained up in pots, and sheltered in winter for 2 or 3 years till they have acquired strength. The seeds frequently remain a whole year in the ground; and therefore the earth in the pots ought not to be disturbed, though the plants do not come up the first year. All the other sorts require to be kept in a warm stove.

ANNONÆ PRÆFECTUS, in antiquity, an extraordinary magistrate, whose business it was to prevent a scarcity of provision, and to regulate the weight and fineness of bread.

ANNOTATION, in matters of literature, a brief commentary or remark upon a book or writing, in order to clear up some passage, or draw some conclusion from it.

ANNOTTO, in commerce, a kind of red dye, brought from the West Indies. It is procured from the pulp of the seed capsules of a tree called bixa in South America. See BIXA.

The annotto is prepared only by the Spaniards; the mode is as follows: the contents of the fruit or capsule are thrown into a wooden bowl, where as much hot water is poured on them as is necessary to suspend the matter or pulp. When the seeds are left quite naked, they are taken out, and the wash is left to settle. The water is then poured off, and the sediment dried by degrees in the shade, after which it is made into balls or cakes for exportation.

ANNUAL, an appellation given to whatever returns every year: thus we say, the annual motion of the earth, annual plants, &c.

ANNUAL, or ANNUEL, in the Scotch law, any yearly revenue, or rent, payable at the two great terms, Whitsuntide, and Martinmas.

ANNUAL *plants*, called also simply annuals, are such as only live their year, *i.e.* come up in the spring, and die again in the autumn.

ANNUAL *leaves*, are such as come in the spring, and perish in autumn.

ANNUENTES MUSCULI, in anatomy, the same with *recti interni minores*.

ANNUITIES, periodical payments of money amounting to a fixed sum in each year, and continuing for a certain period, as for 10, 50, or 100 years, or for an uncertain period, to be determined by a particular event, as on the failure of a life, or for an indefinite term; which latter are called perpetual annuities. The times of payment are either yearly, half yearly, quarterly, weekly, or at any other intervals that may be determined on previous to the commencement of the annuity, or regulated during its continuance.

All calculations relating to annuities are made on the principle of improving money at Compound Interest, and are generally for an annuity of 1*l.* from which the value of any other annuity is easily derived. Let r represent the amount of 1*l.* in one year; that is, one pound increased by a year's interest, then r^n, or r, raised to the power whose exponent is any given number of years, will be the amount of 1*l.* in those years; its increase in the same time is $r^n - 1$; now the interest for a single year, or the annuity answering to the increase, is $r - 1$; therefore, as $r - 1$ is to $r^n - 1$, so is u, any given annuity, to a its amount. Hence we have

$$\frac{u \times r^n - 1}{r - 1} = a,$$

by which the amount of an annuity for any number of years at any given rate of interest is found. In the same manner the present value of annuities is obtained; for, as 1*l.* is the present value r^n, its amount in n years, and as the present value of any other amount, and consequently of $\frac{u \times r^n - 1}{r - 1}$ must bear the same proportion to that amount, we have

$$\frac{u \times 1 - \frac{1}{r^n}}{r - 1}, \text{ or } \frac{u - \frac{u}{r^n}}{r - 1} = p.$$

From these theorems, the other cases relating to annuities may be easily deduced; but as the involution of high powers is a tedious operation by common arithmetic, most questions relative to annuities may be more conveniently answered by the help of logarithms. It is however,

seldom necessary to have recourse to either of these methods, as very accurate tables of the amount and present worth of annuities have been calculated by Mr. J. Smart and others, and are inserted in most books that treat of Compound Interest or Annuities.

TABLE I.

Showing the Amount of an Annuity of 1*l*, in any Number of Years, not exceeding 100, when improved at 5 per Cent. per Annum, Compound Interest.

Yrs.	Amount.	Yrs	Amount.	Yrs.	Amount.
1	1,0000	35	90,3203	69	559,5510
2	2,0500	36	95,8363	70	588,5285

33	80,0638	67	505,6698		
34	85,0670	68	531.9533		

EXAMPLE.

To what sum will an annuity of 42*l*. amount in 30 years, at 5 per cent. compound interest? The amount in the Table against 30 years is 66,4388, which multiplied by 42, gives the answer 2790*l*. 8*s*. 7*d*.

TABLE II.

Showing the present Value of an Annuity of 1*l*. for any Number of Years, not exceeding 100, at 5 per Cent. per Annum, Compound Interest. By the help of these tables many practical problems, which are daily occuring, may be worked by any persons versed in common arithmetic.

Yrs	Value.	Yrs.	Value.	Yrs.	Value.
1	,952381	35	16,374194	69	19,309810

31	15,592810	65	19,161070	99	19,840306
32	15,802677	66	19,201019	100	19,847910
33	16,002549	67	19.239066		
34	16 192904	68	19.275301		

EXAMPLE.

What is the present worth of an annuity of 30*l*. to continue for 16 years, at 5 per cent. compound interest? The value in the Table against 16 years is 10,83777, which multiplied by 30, gives the answer 325*l*. 2*s*. 7*d*.

Reversionary Annuities are those which do not commence till after a certain number of years, or till the decease of a person, or some other future event, has happened. The present value of an annuity which is not to commence till the expiration of a certain period, may be found by Table II, by deducting from the value of an annuity for the whole period, the value of an annuity to the time at which the reversionary annuity is to commence.

Example. What is the present value, at 5 per cent. compound interest, of 50*l*. per annum for 20 years, commencing at the end of 7 years from the present time? The value of an annuity for 27 years is 14,643034, and the value of an annuity for 7 years is 5,786373, the latter deducted from the former leaves 8,856661, which multiplied by 50, gives 442*l*. 16*s*. 7*d*. the value of the reversionary annuity.

For the value of Annuities on Lives, and of Reversionary Annuities on Lives or Survivorship, see LIFE ANNUITIES.

ANNUITIES, *Public.* See NATIONAL DEBT and FUNDS.

ANNUITY, in law, a contract very distinct from a rent charge, with which it is frequently confounded; a rent charge being a burthen imposed upon, and issuing out of

ands, whereas an annuity is a yearly sum, chargeable only upon the person of the granter. Therefore, if a man by deed grant to another the sum of 20*l.* per annum, without expressing out of what lands it shall issue, no land at all shall be charged with it; but it is a mere personal annuity, which is of so little account in the law, that if granted to an eleemosynary corporation, it is not within the statutes of mortmain; and yet a man may have a real estate in it, though his security is merely personal. Blacks. Com. b. ii. chap. 3.

For the provisions respecting grants of annuities for lives, see LIFE ANNUITIES.

ANNULAR, in anatomy, something in the form of, or resembling a ring. Hence, the annular cartilage is the second cartilage of the larynx; annular ligament that which encompasses the wrist, and binds the bones of the arm together; annular process, or protuberance, a part of the medulla oblongata. The sphincter muscle of the anus is, from its figure, called the annular muscle.

ANNULAR *eclipse*. See ASTRONOMY.

ANNULET, in architecture, a small square member in the Doric capital, under the quarter round. Annulet is also a narrow flat moulding, which is common to divers places of the columns, as in the bases, capitals, &c. It is the same member which Vitruvius calls a fillet; Palladio a listel or cincture; Scamozzi and Mr. Brown, a supercilium, list, tinea, eyebrow, square and rabbit.

ANNULET, in heraldry, a mark of distinction which the fifth brother of a family ought to bear in his coat of arms.

ANNULLING, a term sometimes used for cancelling or making void a deed, sentence, or the like.

ANNULUS, a ring, in geometry, the area of which is equal to the difference of the areas of the outer and inner circles: or it may be found by multiplying the sum of their diameters by the difference, and the product by 7854.

ANNUNCIADA, ANNUNTIADA, or ANNUNTIATA, an order of knighthood in Savoy, first instituted by Amadeus I. in the year 1409.

ANNUNCIADA, is also the title of several religious orders instituted at different times, and at different places, in honour of the Annunciation.

ANNUNCIATION, the tidings brought by the angel Gabriel to the Virgin Mary; a festival on the 25th of March, vulgarly called lady day.

In the Romish church, on this feast, the pope performs the ceremony of marrying or cloistering a certain number of maidens, who are presented to him in the church della Minerva, clothed in white serge, and muffled up from head to foot: an officer stands by, with purses containing notes of fifty crowns for those who make choice of marriage, and notes of an hundred for those who choose the veil.

ANNUNTIATOR, the name of an officer in the church of Constantinople. It was his business to inform the people of the festivals that were to be celebrated.

ANODYNE, in pharmacy, a term applied to medicines which mitigate pain.

ANOLYMPIADS, ἀναλυμπιάδες, in Grecian antiquity, an appellation given by the Elæans to such Olympic games as had been celebrated under the direction of other states besides themselves.

Anomalistical *year*, in astronomy, the time that the earth takes to pass through her orbit: it is also called the periodical year. The space of time belonging to this year is greater than the tropical year, on account of the precession of the equinoxes.

ANOMALOUS *verbs*, in grammar, such as are not conjugated conformably to the paradigm of their conjugation.

ANOMALY, in astronomy, an irregularity in the motion of the planets, whereby they deviate from the aphelion or apogee; which inequality is either mean, eccentric, or coequate and true. See ASTRONOMY.

ANOMIA, in conchology, the name of an extensive genus of bivalves, defined as inequivalve, one valve gibbous toward the beak, the other flat and perforated near the hinge. The animal, which is but imperfectly known, is described: body thin and slender, emarginated, and fringed; the hairs affixed to the upper valve; and it has two arms, which are linear and longer than the body. Some conchologists separate the fossile kinds from those which are found in a recent state. There are 25 species, among which is the anomia terebratula. See Plate VII. Nat. Hist. fig. 21.

ANOMOEANS, a sect of Christians, who asserted that the Son was of a nature different from, and in nothing like to that of the Father. This was the name by which the pure Arians were distinguished, in contradistinction to the semi Arians, who acknowledged a likeness of nature in the Son, at the same time that they denied, with the pure Arians, the consubstantiality of the Word. The semi Arians condemned the Anomœans in the council of Seleucia; and the Anomœans in their turn condemned the semi Arians in the council of Constantinople.

ANOMORHOMBOIDIA, in natural history, a genus of crystaline spars, of no determinate form, easily fissile, but cleaving more readily in an horizontal than in a perpendicular direction, their plates being composed of irregular arrangements of short and thick rhomboidal concretions. See MINERALOGY.

ANONIS, *rest harrow*, in botany, a genus of plants, the flower of which is papilionaceous, and its fruit a turgid villose pod, containing a few kidney like seeds.

This genus belongs to the diadelphia decandria class of Linnæus, who calls it *ononis*. The essential character is, calyx quinquepartite; segments linear; vexillum striated; legumen turgid and sessile; filaments coatited, without a fissure.

ANSÆ, in astronomy, the parts of Saturn's ring, which are to be seen on each side of the planet, when viewed through a telescope, and the ring appears somewhat open. They are so called because they are like handles to the body of the planet.

ANSEL *weight*, the same with auncel weight.

ANSER, the trivial name of the common goose. See ANAS.

ANSER, in astronomy, a star of the fifth or sixth magnitude, in the milky way, between the swan and eagle.

ANSPESSADES, in the French armies, a kind of inferior officer in the foot, below the corporals, but above the common sentinels. There are usually four or five of them in a company.

ANT, in entomology, a well known insect, much celebrated for its industry and economy. See FORMICA and TERMES.

ANTA, in the ancient architecture, a square pilaster, placed at the corners of buildings. Anta is used by M.

Le Clerc for a kind of shaft of a pillar, without base or capital, and even without any moulding.

ANTACIDS, in pharmacy, an appellation given to all medicines proper to correct and resist acid, or sour humours. See MATERIA MEDICA.

ANTAGONIST, *muscles*, in anatomy, those which have opposite functions, as flexors and extensors, abductors and adductors, &c. See ANATOMY.

ANTALKALINES, in the materia medica, signifying medicines fitted to correct alkaline salts, or alkaline matters in the whole body.

ANATANACLASIS, in rhetoric, a figure which repeats the same word, but in a different sense, as *dum vivimus, vivamus*. And the English, *Let the dead bury the dead*.

ANTANAGOGE, in rhetoric, a figure by which, when the accusation of the adversary is unanswerable, we load him with the same or other crimes. This is usually called *recrimination*.

ANTANISOPHYLLUM, in botany. See BOERHAAVIA.

ANTARCTIC, in the general sense, denotes something opposite to the arctic, or northern pole. Hence,

ANTARCTIC *circle*, in geography and astronomy, is one of the lesser circles of the sphere, and distant only 23° 30′ from the south pole, which is likewise called antarctic, for the same reason.

ANTARES, a star of the first magnitude, otherwise called the Scorpion's heart. See SCORPION.

ANTE′, in heraldry, denotes that the pieces are let into one another in such form as is there expressed; as, for instance, by dove tails, rounds, swallows' tails, or the like.

ANTEAMBULONES, in Roman antiquity, servants who went before persons of distinction to clear the way before them. They used this formula, *Date locum domino meo; i. e.* make way for my master.

ANTECEDENT, in grammar, the word to which a relative refers: thus, *God whom we adore*, the word God is the antecedent.

ANTECEDENT, in logic, is the first of the two propositions in an enthymema.

ANTECEDENT, in mathematics, is the first of two terms of a ratio, or that which is compared with the other, as in the ratio of 2 to 3, or a to b, 2 and a are each antecedents.

ANTECEDENT *signs*, in medicine, such as are observed before a distemper is so formed as to be reducible to any particular class, as a bad disposition of the blood.

ANTECEDENT *term*, in mathematics, the first one of any ratio: thus, if the ratio be $a : b$, a is the antecedent term.

ANTECEDENTIA, in astronomy, an apparent motion of a planet toward the west, or contrary to the order of the signs, *viz.* from Taurus toward Aries, &c.

ANTEDATE, among lawyers, a spurious or false date, prior to the true date of a bond, bill, &c.

ANTEDILUVIAN, whatever existed before Noah's flood: thus, the generations from Adam to Noah are called the antediluvians. There have been great disputes among philosophers about the form, constitution, figure, and situation of the antediluvian earth. Dr. Burnet contended that it was only a hollow crust, with an uniform equable surface, without mountains and without seas, and in all respects different from what we now find it to be. Dr. Woodward undertook to prove that its appearance was the same as at present; that it had the same position in respect of the sun, and consequently the same vicissitudes of seasons: and Mr. Whiston imagined that the chaos of which our earth was formed, had been the atmosphere of a comet; that the annual motion of the earth began as soon as it assumed a new form; but that the diurnal motion did not take place till the fall of Adam; that before the deluge the year began at the autumnal equinox; that the orbit of the earth was a perfect circle; and that the solar and lunar years were the same, each consisting of just three hundred and sixty days. The state of the antediluvian philosophy has been the subject of much debate among authors, and so also has the state of the population.

ANTEJURAMENTUM, by our ancestors called *juramentum calumniæ*, an oath which anciently both accuser and accused were to take before any trial or purgation.

The accuser was to swear that he would prosecute the criminal; and the accused to make oath, on the day he was to undergo the ordeal, that he was innocent of the crime charged against him.

ANTELOPE, in zoology, a genus of quadrupeds. The generic character is, horns hollow, with a bony core, pointing upward, annulated or wreathed, permanent; front teeth, in the lower jaw, eight; no canine teeth. Antelopes have but lately been included in a separate genus; they were formerly placed under that of the goat. They form a link indeed between the goat and deer kind, but possess sufficiently distinctive marks to entitle them to stand apart from them both. They are in general natives of the hottest part of the globe, and peculiarly of Asia and Africa, Europe having but two species, and America none.

Antelopes have a slender elegant make, and are singularly agile and swift in their motions: they are restless, timid, vigilant, and full of animation. Their chase is a favourite amusement in the east; and such is their speed, that the fleetest dogs cannot overtake them; on which account falcons are trained to assail them, and by pecking at their eyes, to check their course, and throw them into confusion. A species of leopard is employed also to steal upon them unawares, and seize them by a few bounds.

Antelopes have the singular property of sometimes stopping short, and gazing at their pursuers. The beauty of their eyes affords a favourite object of comparison to eastern poets. They usually prefer hilly countries, and associate in numerous herds. They graze on herbage, or crop the shoots of trees, and their flesh is generally of a very delicate flavour. There are twenty-eight species of the antelope.

1. Oryx, or Egyptian antelope. The Egyptian antelope, or pasan, is more easily distinguished than many others in this extensive race; the horns affording a character perfectly clear and constant; they are almost entirely straight, nearly three feet in length, very slender in proportion to their length, annulated at the lower part or toward the base, the remainder smooth and gradually tapering to the point. The size of the animal is somewhat superior to that of a deer.

The pasan is nearly four feet high, measured from the top of the shoulders to the ground: it is found about the Cape of Good Hope, as well as in other parts of Africa.

2. Leucoryx, or white antelope. The leucoryx is entirely milk white, except the markings on the face and limbs: these are described as of a red colour, and not black, as in the pasan; the nose is thick and broad, like that of a cow; the ears somewhat slouching; the body heavy; the limbs somewhat less so; the horns very long, very slightly incurvated, slender, and annulated about half way upward; their colour is black, and they are sharp pointed; the hoofs are black, and the tail somewhat flocky, or terminated by loose hairs. The size of this species is compared by Mr. Pennant to that of a Welch runt. It is an inhabitant of an island called Gow Bahrein, in the gulf of Bassora.

3. Antilope gazella, or algazel. This species is a native of India and Persia, and is also found in many parts of Africa. It is about the size of a fallow deer, and is of a reddish or bright bay colour, with a white breast: the horns are very long, thin, and black, nearly upright, bending inward at their extremities; they are nearly smooth; the rings with which they are marked being very slight, except near the base, where they are somewhat more distinct: they are almost three feet in length.

In celerity and general manners this species agrees with many others of its tribe, and is said to be easily tamed.

4. Oreas, or Indian antelope. This is one of the largest of the whole genus, and is found both in India and Africa, living in numerous herds. It is not much inferior in size to a cow, and is of a bluish gray or slate colour, with the head of a bright bay. Along the upper part of the neck and a part of the back, runs a coarse black mane: on the breast is a very large pendent tuft of hair, as in the nilghau: the tail is also tipped with long black hairs; the horns are extremely stout, straight, sharp pointed, and marked with two very thick prominent wreaths or spires: they are sometimes above two feet in length, and are of a blackish colour. The oreas is said to be an animal of great strength, and it has been thought not impracticable to train it to agricultural purposes, in the same manner as the horse or ox. It is said sometimes to grow extremely fat, so as to be easily run down. The flesh is reckoned extremely good; and the skin is very strong and serviceable for the purpose of leather. The female is said to be horned like the male.

5. Antilope ourebi, or ourebi. This is described by Mr. Pennant as the antelope with small straight horns, small head, long neck, long pointed ears: colour above a deep tawny, brightening toward the sides, neck, head and legs; lower part of breast, belly, buttocks, and inside of thighs, white: tail only three inches long, and black: hair on the body short, under the chest long and whitish, on each knee a tuft of hair. The females are hornless: length three feet nine inches to the tail: inhabits the country very remote from the Cape of Good Hope. Seldom more than two are seen together. They generally haunt the neighbourhood of fountains surrounded with reeds; are excellent venison.

6. Antilope oreotragus, or klipspringer. This species is to be numbered among the late acquisitions in natural history, having been first described by Dr. Forster.

7. Scripta, or harnessed antelope. This, which is numbered among the smaller antelopes, is of an elegant tawny chesnut colour both above and below, each side of the body being marked by two longitudinal bands of white, crossed, at nearly equal distances, by two transverse ones: the rump is also marked on each side by two white descending stripes; and the thighs are variegated with seven or eight roundish white spots: the cheeks have a white spot or patch beneath the eye, and the under part of the throat is of the same colour: the tail measures ten inches, and is covered with long and rough hair: the horns point backward, and are nine inches long, of a black colour, and marked by two spiral ribs or wreaths. This elegant species is a native of Senegal, living in woods in large herds.

8. Grimmia, or Guinea antelope. The Guinea antelope, or grimm, is considerably smaller than a roebuck, and is of an elegant and lively aspect. Its colour on all parts except the throat, abdomen, and insides of the thighs, where it is pale cinereous, is a beautiful light yellowish or tawny brown. Like most other quadrupeds, however, it differs as to the intensity of its colour. The horns are very short, thick at the base, very slightly annulated to a small distance beyond, and are sharp pointed, smooth, and black: the limbs are slender; the tail rather short, blackish above, white below, and is somewhat flocky or loose haired: but what principally distinguishes this species is an upright pointed tuft of strong black hairs rising from the top of the forehead, between the horns, to the height of about two inches and a half: the sinus lachrymalis, as in many other antelopes, is extremely conspicuous. The grimm is found in several parts of Africa, extending, according to Dr. Pallas and Mr. Pennant, from Guinea to the Cape of Good Hope; residing principally in places overgrown with brushwood, into which it may retire on the approach of danger.

9. Pygmæa, or pigmy antelope. This beautiful and diminutive species appears to have been frequently confounded with the *moschus pygmæus*, or pygmy musk, which it resembles in size as well as in colour and manners. It is a native of the hottest parts of Africa, and is easily tamed, but is of so tender a nature as not to admit of being brought in a living state into Europe. So remarkable are its powers of activity in its native regions, that it is said to be able to leap over a wall of twelve feet high. Its colour is a bright bay, paler beneath, and on the insides of the limbs; and its height not more than nine inches. The horns are straight, short, strong, sharp pointed, smooth, and perfectly black. The legs are scarcely thicker than a quill, and have been used for similar purposes with those of the moschus pygmæus. The female is said to be hornless.

10. Antilope picta, or nilghau. The nilghau, or white footed antelope, is a large and beautiful species, known only within the space of a few years past. It has of late years been often imported into Europe, and has bred in England. In confinement it is generally pretty gentle, but is sometimes seized with fits of sudden caprice, when it will attack with great violence the objects of its displeasure. When the males fight, they drop on their knees at some distance from each other, and gradually advance in that attitude, and at length make a spring at each other with their heads bent low. This action, however, is not peculiar to the nilghau, but is observed in many others of the antelope tribe. See Plate VII. Nat. Hist. fig. 22.

11. Tragocamelus, or Indostan antelope. The Indostan antelope is of a far less elegant appearance than the rest of the antelopes, and seems to partake, in some

degree, of the form of a camel, having a strong bending neck, and a large elevation or protuberance over the shoulders. Along the neck runs a short mane; and the protuberance before mentioned is covered or tufted with long hair: the breast is furnished with a kind of dewlap, or loose pendent skin, resembling that of a cow: the hind part of the animal is small in proportion to the fore; the limbs are slender, and the tail is nearly two feet in length, and terminated by a hairy tuft. This highly singular animal is a native of India, and in its habits and manner of lying down is said to resemble a camel.

12. Bubalis, or cervine antelope. This species is said to be common in Barbary, and in all the northern parts of Africa. It is also found, though less frequently, in many other parts of that continent, and even extends as far as the Cape of Good Hope. It is supposed to have been the bubalas of the ancients, instead of the common buffalo, as sometimes erroneously imagined. In its general form it seems to partake of the stag and heifer, having a large head, like that of an ox; and a thick broad nose. The height of the animal, when measured to the top of the shoulders, is about 4 feet; the general colour a reddish brown, white about the rump, insides of the limbs, and lower part of the belly; the upper part of the fore legs is marked in front by a dusky patch, as is also the hind part of the thighs; and on the upper part of the back is a stripe of the same colour. The horns bend outward and backward, and are very strong and black, thickly or coarsely annulated toward the base, and seated pretty close to each other on the head; they are about 20 inches in length, and 11 inches round at the base; the teeth are large, the lower lip black, with a sort of tuft of bristles on each side; along the snout and forehead runs a black band, terminated at the forehead by a tuft of hair between the horns.

13. Strepsiceros, or striped antelope. The striped antelope is a native of the country about the Cape of Good Hope, where it is said to be called coedoes. It is one of the larger kinds of antelopes, measuring near 9 feet in length, and being 4 feet high. Its colour is a rufous gray, with the face brown, marked by two white lines, each proceeding from the corner of the eye, and uniting in a pointed form on the top of the nose, which is smooth and black; down the forehead runs a broad dusky stripe, and a streak of the same colour is continued down the upper part of the neck; the lower part of the back is marked by a white stripe, from which proceed several others, each about an inch broad, down the sides of the animal, three or four of them falling over the upper part of the thighs: the female of this species is said by Mr. Pennant to be destitute of horns, but Dr. Pallas affirms that it is horned like the male. The number of white stripes in this animal seems to vary.

14. Rupcapra, or common antelope. Of this numerous tribe there is perhaps no species more truly elegant in its appearance than the present, which is a native of many parts of Africa, as well as of India. It is particularly frequent in Barbary. Its general size is somewhat smaller than that of a fallow deer, and its colour is a reddish tawny brown above, and white below; the insides of the limbs are white, and on the head, back, and outsides of the limbs, the hair is darker than on other parts: the orbits of the eyes are white, and this colour is generally continued into a white spot or patch on each side the forehead; the muzzle is black; the horns are of a peculiarly beautiful form, having a double flexure, first inward and again outward: their colour is black, and they are very elegantly and distinctly marked throughout almost their whole length by numerous prominent rings. Their general length is about fourteen inches, and they are about sixteen inches distant from each other at the tips. See Plate VII, Nat. Hist. fig. 23.

15. Lerwia, or Gambian antelope. This seems a species not very distinctly understood.

16. Antilope saiga, or saiga. The saiga, or Scythian antelope, is an inhabitant of all the deserts from the Danube and the Dnieper to the river Irtish, but not beyond; nor is it ever seen to the north of 54 or 55 degrees of latitude. It is therefore found in Poland, Moldavia, about Mount Caucasus, and the Caspian Sea, as well as in the dreary open deserts of Siberia, where salt springs abound, feeding on the salt, acrid, and aromatic plants of those countries.

The females of this species go with young the whole winter, and bring forth in the northern deserts in May, producing only one young at a birth, which is covered with a soft curling fleece, like that of a new fallen lamb. It is said that a flock of saigas seldom lies down all at once, some always acting as a kind of sentinels, and being relieved in their turn by others; and thus they preserve themselves from the attacks both of wolves and hunters. They are so extremely swift as easily to outstrip the fleetest horse, but cannot run for any great length of time in this manner without stopping, as if to take breath. If bit by a dog, they instantly fall down, without attempting to rise, being entirely disabled through extreme terror. In their flight they appear to incline to one side, and their course is so rapid, that they scarcely seem to touch the ground with their feet. When taken young they may be easily tamed; but when caught at full age, are so wild and obstinate as to refuse all kinds of food.

These animals are hunted for the sake of their flesh, horns, and skins, which latter are said to be excellent for gloves, belts, &c. The hunters are careful to approach them against the wind, lest the animals should perceive them by their smell: they also avoid putting on red or white clothes, or any colours which might attract their notice. They are both shot and taken with dogs, and sometimes by a species of eagle trained to this kind of falconry.

17. Gutturosa, or Chinese antelope. This is a species which is said to abound in the southern parts of the deserts between Tibet and China, and in the country of the Mongol Tartars, frequenting principally the dry and rocky plains and hills of those regions, and feeding on the finer and more aromatic plants. It is said to be so averse to water, that it will not go into it even to save its life, when driven by dogs to the brink of a river. If taken young it may be easily tamed. Its flesh is much esteemed as a food, and the horns are in great request among the Chinese for various purposes. The female has no horns.

18. Subgutturosa, or Guldensted's antelope. This species was first described by Mr. Guldensted, in the Petersburg Transactions. It is found in Persia, between the Caspian and the Black Seas; its size and general appearance is that of a roebuck, of a gregarious nature, and it feeds principally on the artemisia pontica.

19. Antilope euchore, or springer.

"This elegant species weighs about fifty pounds, and is rather less than a roebuck; inhabits the Cape of Good Hope; called there the *spring bock*, from the prodigious leaps it takes on the sight of any body. When alarmed it has the power of expanding the white space about the tail into the form of a circle, which returns to its linear form when the animal is tranquil. They migrate annually from the interior parts in small herds, and continue in the neighbourhood of the Cape for two or three months, then join companies, and go off in troops, consisting of many thousands, covering the great plains for several hours in their passage; are attended in their migrations by numbers of lions, hyænas, and other wild beasts, which make great destruction among them; are excellent eating, and, with other antelopes, are the venison of the Cape. They make periodical migrations in seven or eight years, in herds of many hundred thousands, from the north, from the interior parts of Terra de Natal. They are compelled to it by the excessive drought which happens in that region, where sometimes there does not fall a drop of rain for two or three years. These animals, in their course, desolate Caffraria, spreading over the whole country, and not leaving a blade of grass. Lions attend them: where one of those beasts of prey are, the place is known by the vast void visible in the midst of the timorous herd. On its approach to the Cape, it is observed that the avant guard is very fat, the centre less so, and the rear guard almost starved, being reduced to live on the roots of the plants devoured by those which went before; but on their return they become the avant guard, and thrive in their turn on the renewed vegetation; while the former, now changed into the rear guard, are famished, by being compelled to take up with the leavings of the others. These animals are quite fearless, when assembled in such mighty armies; nor can a man pass through, unless he compels them to give way with a whip or a stick. When taken young, they are easily domesticated: the males are very wanton, and are apt to butt at strangers with their horns."

20. Antilope arundinacea, or ritbock. The ritbock, or ritrebock, is so named from its chiefly frequenting reedy places. Its size is that of a roebuck, and its colour a very elegant pale gray, with the throat, belly, hips, and insides of the limbs, white, but without any dusky line of separation along the sides of the body, as in many other antelopes.

21. Antilope sylvatica, or bosbock. In its general form this seems most allied to the harnessed antelope, but is said to be rather smaller. Like that species, it inhabits woods, and is found at a great distance above the Cape of Good Hope. Its colour is a dark brown above, and white beneath; the head and neck having somewhat of a rufous cast, and the thighs are marked with several small round white spots.

22. Eleotragus, or cinereous antelope. This appears to be an elegant species, and is supposed to be a native of Africa. The head, hind part, and sides of the neck, back, sides, shoulders, and thighs, of a most elegant grayish ash colour; front of the neck, breast, belly, and legs, pure white; horns marked with spiral wreaths. Mr. Pennant places it among those whose horns incline forward.

23. Dorcas, or Barbary antelope. This species is about half the size of a fallow deer; its colour is reddish brown above, and white beneath; the two colours being separated by a dark or blackish lateral line or stripe; on each knee is a tuft of blackish hair; the horns are 12 inches long, of a round or cylindric form, and incline first backward, then bend in the middle, and lastly, revert forward at their tips; they are of a black colour, and are annulated with about 13 rings on the lower part.

24. Kevella, or flat horned antelope. This animal in its general appearance, so exceedingly resembles the Barbary antelope, that it might readily pass for a variety of the same species, was it not that the horns, instead of being round, are flattened on their sides, and marked by somewhat more numerous rings. Its size is that of a small roebuck, and it is chiefly found in Senegal, but is said to occur also in Barbary and in Persia. It lives in large flocks, and has an odour resembling that of musk.

25. Pygarga, or white faced antelope. So great is the similitude between this species and the flat horned antelope, that the chief difference appears to consist in size; this being larger than a fallow deer. The horns resemble those of the animal before mentioned, and are 16 inches long, and about 5 between tip and tip; they are very strongly annulated in the male, but said to be nearly smooth in the female; the face is white; the cheeks and neck, in the living animal, of a bright bay; the back and upper parts of ferruginous brown, with a dark stripe down the back: the belly and rump white, as is also, in the Leverian specimen, the lower half of the legs; the sides of the body are marked, as in many others of this genus, with a dark or blackish stripe; the tail is about seven inches long, covered with black hairs, which extend some inches beyond the end.

26. Antilope corinna, or corine. The corine is somewhat smaller than a roebuck, and is a native of Senegal and other parts of Africa.

27. Sumatrensis, or Sumatran antelope. The Sumatran antelope was first mentioned by Mr. Marsden, in his account of that island, under the name of cambing ootan, or goat of the woods.

28. Leucophæa, or blue antelope. This is a species of very considerable size, being larger than a fallow deer, and from the form of its horns, and the length of its hair, may be said to connect, in some degree, the antelope with the goats.

ANTENNÆ, in the history of insects, slender filaments with which nature has furnished the heads of these creatures, being the same with what in English are called horns or feelers.

The structure of the antennæ in different insects is thus characterized. Setaceæ, those which resemble a bristle: Filiformes, uniform, like a thread: Moniliforms, like the filiform, but consisting of a series of round knots: Clavatæ, club shaped, increasing from the base to the extremity: Capitatæ, like the former, but the last articulation larger than the rest, and forming a capital or head: Fissiles are capitatæ, but have the head divided horizontally into laminæ: Perfoliatæ are likewise capitatæ, but the head divided horizontally, and connected by a kind of thread that passes through the centre: Pectinatæ, resembling a comb or feather, having lateral appendages on both sides: Aristatæ, have a lateral hair, which is either naked or furnished with lesser hair.

ANTEPAGMENTA, in the ancient architecture, the jambs of a door. They are also ornaments in carved work,

of men, animals, &c. made either of wood or stone, and set on the architrave.

ANTEPENULTIMA, in grammar, the last syllable but two from the end of a word.

ANTEPREDICAMENTS, among logicians, certain preliminary questions, which illustrate the doctrine of predicaments and categories. They are so called because Aristotle has placed them before the predicaments, in order to treat that subject afterward without interruption.

ANTESIGNANI, in the Roman armies, soldiers placed before the standards, in order to defend them, according to Lipsius; but Cæsar and Livy mention the antesignani as the first line, or first body, of heavy armed troops. The velites, who used to skirmish before the army, were likewise called antesignani.

ANTESINISTRA, a name given by the augurs of Rome to thunderbolts, or birds, which proceeded from the south and passed to the east, and were supposed to afford unfavourable presages.

ANTESTARI, denoted to bear witness against any one who refused to make his appearance in the Roman courts of judicature on the day appointed, according to the tenor of his bail. He might then be brought by force into court, some persons being called to bear witness of the fact.

ANTHELION, a mock sun, or meteor, seen through the clouds, larger than the disk of the sun. In its most refulgent state it is yellow as the sun, but the lucid tract surrounding it is of a paler yellow, interspersed with reddish spots.

ANTHELIX, in anatomy, the inward protuberance of the external ear, being a semicircle within, and almost parallel to the helix.

ANTHELMINTICS, medicines to destroy worms. See Materia Medica.

ANTHEMIS, chamomile, a genus of the polygamia superflua order, belonging to the syngensia class of plants; and in the natural method ranking under the 49th order, compositæ discoides. The essential characters are these; the receptaculum is chaffy; there is no pappus; the calyx is hemispheric and subequal; and the florets of the ray are more than five. Of this genus there are 19 species, of which the most remarkable are the following:

1. Anthemis Arabica has a branching empalement. It grows near two feet high, with an upright stem, having a single flower at the top, from whose empalement there are two or three footstalks, each having a single flower smaller than the first, like the childing marigold, or hen and chicken daisy.

2. Anthemis nobilis, or common chamomile, grows in plenty upon commons, and other waste land. There is a variety with double petals. Formerly this plant was used for planting of walks, which, when mowed and rolled, looked well for some time; but it was subject to decay in large patches, and the walks became unsightly.

3. Anthemis pyrethrum, or pellitory of Spain, is a perennial plant, which grows naturally in Spain and Portugal. The branches trail upon the ground. At the extremity of each branch is produced one large single flower, like chamomile, but much larger; the rays of which are of a pure white within, but purple on the outside. The seeds will not come to perfection in this country.

4. Anthemis tinctoria is a perennial plant, which flowers from June to November, and makes a very pretty appearance, some of the flowers being of a white, others of a sulphur, and some of a bright yellow colour. Of these the nobilis and the pyrethrum are chiefly used in medicine. They are accounted carminative, aperient, emollient, and in some measure anodyne. These flowers are frequently also used externally in discutient and antiseptic fomentations, and in emollient clysters. An essential oil was formerly directed to be prepared from them, but it is now omitted. A simple watery infusion of them taken in a tepid state, is at present frequently employed to promote the operation of emetics.

ANTHERA, among botanists, that part of the stamen which is fixed on the top of the filamentum, within the corolla; it contains the pollen or fine dust, which, when mature, it emits for the impregnation of the plant.

ANTHERICUM, spider wort, a genus of the monogynia order, belonging to the hexandria class of plants; and, in the natural method, ranking under the 10th order, coronariæ. The essential character is, corolla of six oblong petals, expanding. The pericarpium is an ovate trisulcated capsule, with three cells and three valves. There are 39 species. The anthericum frutescens was formerly known among the gardeners near London by the name of onion leaved aloe. It produces many ligneous branches from the root, each supporting a plant with long taper leaves, in shape like those of an onion, and full of a yellow pulp very juicy. The flowers are yellow, produced on long loose spikes. It is a native of the Cape of Good Hope, and requires shelter in winter.

The anthericum liliastrum is a perennial plant; it flowers in June and July, and is known by the name of St. Bruno's lily.

ANTHESTERIA, in Grecian antiquity, festivals celebrated in the spring by the ancient Athenians, in honour of Bacchus, during which the masters feasted their slaves, as the Romans did in the time of the Saturnalia. It was usual, during these feasts, to ride in chariots, and pass jests upon all that passed by.

ANTHISTIRIA, in botany, a genus of the trigynia order, belonging to the triandria class of plants, and, in the natural method, ranking under the 4th order, gramina. The essential character is: the corolla, a two valved glume, cleft at the base into four divisions. There is only one species of this grass, the ciliata or fringed anthistiria, a native of India.

ANTHOCEROS, or horn flower, a genus of the order of algæ, belonging to the cryptogamia class of plants, and, in the natural method, ranking under the 57th order, algæ. The essential characters are: the calyx of the male is sessile, cylindric, and entire; the anthera, one, is subulated, very long, and two valved; the calyx of the female is monophyllous, divided into six parts, and expanding; the seeds are about three, naked and roundish. There are only three species of the anthoceros, *viz.*

1. Anthoceros levis, a native of Europe and America.

2. Anthoceros multifidus, a native of Germany, found in moist shady places, and on heaths.

3. Anthoceros punctatus, or spotted anthoceros, a native of Britain.

ANTHOLOGION, the title of the service book used in the Greek church. It is divided into twelve months

containing the offices sung throughout the year, on the festivals of our Saviour, the Virgin, and other remarkable saints.

ANTHOLOGY, ανθολογια, a discourse of flowers, or of beautiful passages from any authors. It is also the name given to a collection of epigrams taken from several Greek poets.

ANTHOLYZA, mad flower, a genus of the monogynia order, belonging to the triandria class of plants; and in the natural method ranking under the 6th order, ensatæ. The essential characters are; the calyx is tubular, irregular, and bent back; and the capsule is beneath the flower. There are 7 species: the most remarkable are; 1. Antholyza ringens. This has red, round, bulbous roots, from which arise several red flowers. These appear in June, and the seeds ripen in September.

2. Antholyza spicata, with narrow furrowed leaves, is in shape and size like the vernal crocus. Between these arise the flower stem, which is a foot and a half high: the flowers come out on one side, and are of a white colour, appear in May, and the seeds ripen in August. Both these species are natives of Africa. In summer they may be placed in the open air, but in winter they must be placed under a hot bed frame, or in the greenhouse, where they are a great ornament when in flower.

ANTHOMANIA, an extravagant fondness for curious flowers. A remarkable instance of this occurred in Holland last century, which ruined many individuals, and was obliged to be put a stop to by the magistrates.

ANTHONY, or knights of St. Anthony, a military order, instituted by Albert duke of Bavaria, Holland, and Zealand, when he designed to make war against the Turks in 1382. The knights wore a collar of gold made in form of a hermit's girdle, from which hung a stick cut like a crutch, with a little bell, as they are represented in St. Anthony's pictures.

ANTHONY'S ST. FIRE, a name sometimes given to the erysipelas.

ANTHOSPERMUM, the amber tree, a genus of the dioecia order, belonging to the polygamia class of plants, and in the natural method ranking under the 17th order, stellatæ. The essential characters are; the calyx of the hermaphrodite flower is divided into four parts; there is no corolla; the stamina are four, and the pistilla two; the germen is beneath the flower. Male and female on the same or separate plants. Of this genus Linnæus mentions three species, *viz.*

1. Anthospermum Æthiopica. 2. Anthospermum ciliare; and 3. Anthospermum herbacea. The first is most generally known in the gardens of the curious. Its beauty consists in its small evergreen leaves, which grow as close as heath. These being bruised between the fingers, emit a very fragrant odour; whence the name amber tree. This plant is easily propagated, by cuttings during any of the summer months, in a border of light earth, where they will take root in six weeks time, provided they are watered or shaded as the season may require; or if they are planted in pots plunged in a moderate hotbed, they will take root the sooner, and there will be a greater certainty of their growing. They must be frequently renewed by cuttings, as the old plants are very subject to decay.

ANTHOXANTHUM, or vernal grass, a genus of the digynia order, belonging to the diandria class of plants; and in the natural method ranking under the 13th order, gramina. The essential characters are; the calyx is a bivalved gluma, with one flower; the corolla is bivalved, obtuse, and without any awn. There are three species, *viz.*

1. Anthoxanthum Indicum, a native of India.

2. Anthoxanthum odoratum, or spring grass, a native of Britain: it is one of the earliest spring grasses, and is extremely common in our fertile pastures. The delightful smell of new mown hay is chiefly from this plant.

ANTHRAX, a Greek term, literally signifying a burning coal, used by the ancients to denote a gem, as well as a disease, more generally known by the name of carbuncle. It is sometimes also used for lithanthrax, or pit coal.

ANTHROPOGLOTTUS, among zoologists, an appellation given to such animals as have tongues resembling that of mankind, particularly to the parrot kind.

ANTHROPOLATRÆ, in church history, an appellation given to the Nestorians, on account of their worshipping Christ, notwithstanding that they believed him to be a mere man.

ANTHROPOLITES, a term denoting the petrifactions of the human body.

ANTHROPOMANCY, a species of divination, performed by inspecting the entrails of a human creature.

ANTHROPOMORPHITES, in church history, a sect of ancient heretics, who taking every thing spoken of God in the Scripture in a literal sense, particularly that passage of Genesis in which it is said 'God made man after his own image,' maintained that God had a human shape.

ANTHROPHAGY, the act of eating human flesh. The origin of this custom, barbarous as it is, some authors trace as high as the deluge. In the southern part of Africa, and in some parts of America, this horrid practice is said still to prevail. Mr. Marsden, in his History of Sumatra, informs us that the battas of that island are anthropophagi. They do not eat human flesh to satisfy hunger, but as a mode of showing an abhorrence of their enemies. The objects of this savage repast are prisoners taken in war. When sentence is pronounced, the unhappy victim is tied to a stake, and when mortally wounded by lances thrown at him by the assembled multitude, they rush upon him, cut pieces from his body with their knives, dip them in a dish, previously prepared, of salt and lemon juice, slightly broil them over a fire, and then devour them with savage enthusiasm.

ANTHROPOSOPHIA, the science of the nature of man, his structure and composition, both internal and external.

ANTHYLLIS, kidney vetch, or lady's finger, a genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The essential characters are; the calyx is ventricose, and the legumen is roundish and covered. There are 17 species, of which the following seem to be most worthy of attention.

1. Anthyllis barba Jovis, or silver bush, has its name from the whiteness of its leaves. This is a shrub which often grows to the height of 10 or 12 feet, dividing into many lateral branches, with winged leaves. The flowers are produced at the extremities of the branches, collected into small heads, of a bright yellow colour.

2. Anthyllis cytisoides, or shrubby woundwort, has long been known in the English gardens. It is a low shrub, seldom rising above two feet high, but sends out many slender branches, with hoary leaves, which are sometimes single, but generally have three oval lobes: the flowers are yellow. This species and the barba Jovis may be propagated by cuttings planted during any of the summer months; they must always be housed in winter.

3. Anthyllis montana, or herbaceous woundwort, with winged leaves, grows naturally in the mountains in the south of France, and in Italy. The flowers are of a purple colour and globular form. They appear in June and July.

4. Anthyllis vulneraria, with unequal winged leaves, is a native of Spain and Portugal, as likewise of Wales. It is a biennial plant, and the flowers are of a bright scarlet colour.

ANTI, a Greek preposition, which enters into the composition of several words, both Latin, French, and English, in different senses. Sometimes it signifies before, as in antichamber, and sometimes opposite or contrary, as in the names of these medicines, antiscorbutic, antivenereal, &c.

ANTIBACCHIUS, in ancient poetry, a foot consisting of three syllables; the two first long, and the last one short.

ANTIBIBLOS, in the civil law, an instrument by which the defendant owns he has received the libel, or a copy of it, and notes the day whereon he received it.

ANTICAUSOTICS, denote medicines against burning fevers.

ANTICHORUS, in botany, a genus of the monogynia order, belonging to the octandria class; of which the essential characters are: the calyx is a four leaved perianthium; the corolla consists of four expanding petals; the pericarpium is a capsule, above, subulated, with four cells, and four valves; the seeds are very numerous. There is but one species, *viz.*

Antichorus depressus, a native of Arabia.

ANTICARDIUM, in anatomy, the hollow part under the breast, commonly called the pit of the stomach, the same with scrobiculum cordis.

ANTICHRESIS, in civil law, a covenant, by which a person borrowing money of another engages to make over his property to the creditor, for the interest of money lent.

ANTICK, in sculpture and painting, denotes a fantastical composure of figures of different natures, sexes, &c. It amounts to the same thing as the French call *grotesque*.

ANTICLIMAX, in rhetoric, is a figure by which the progress of a discourse descends from great to little.

ANTICUM, in architecture, a porch before a door; also that part of a temple that lies between the body of the temple and the portico.

ANTICUS, a term used by anatomists, importing that the part with which it is joined stands before some others; serratus anticus, peronæus anticus, tibialis anticus, &c. See ANATOMY.

ANTIDACTYLUS, a name to a foot of poetry, the reverse of dactyl, consisting of three syllables, the first two short, and the last long.

ANTIDESMA, in botany, a genus of the dioecia order, belonging to the pentandria class of plants. The calyx of the male is five leaved; there is no corolla: the antheræ are bifid; the female calyx is five leaved; the corolla is wanting; the stigmata are five; the berry is cylindric and one seeded. There are three species, natives of India.

ANTIDICOMARIANTES, in church history, heretics who maintained that the Virgin Mary did not preserve a perpetual virginity.

ANTIDORON, a name given by the Greek church to the consecrated bread, part of which was given to the poor.

ANTIENT, in a military sense, denotes either the ensign who carries them, or the colours; in ships of war, the streamer or flag, borne in the stern.

ANTIHECTICS, medicines good in hectical disorders. See PHARMACY.

ANTILOGARITHM, the complement of a logarithm.

ANTIMONY, in natural history, one of the semimetals, separated by fusion from a very hard and heavy lead coloured substance, called ore of antimony: this ore is composed of a number of extremely small sparkling granules, which give it the appearance of a lump of the purest steel, when fresh broken.

I. Antimony is of a grayish white colour, and has a good deal of brilliancy. Its texture is laminated, and exhibits plates crossing each other in every direction, and sometimes assuming the appearance of imperfect crystals. Hauy has with great labour ascertained that the primitive form of these crystals is an octahedron, and that the integrant particles of antimony have the figure of tetrahedrons. When rubbed upon the fingers, it communicates to them a peculiar taste and smell. Its specific gravity is, according to Brisson, 6.702; according to Bergmann, 6.86. It is very brittle, and may be easily reduced in a mortar to a fine powder. Its tenacity has not been tried. When heated to 809 degrees Fahrenheit, or just to redness, it melts. If after this the heat is increased, the metal evaporates. On cooling, it assumes the form of oblong crystals, perpendicular to the internal surface of the vessels in which it cools. It is to this crystalization that the laminated structure which antimony always assumes is owing.

II. When exposed to the air, it undergoes no change except the loss of its lustre. Neither is it altered by being kept under water. But when steam is made to pass over red hot antimony, it is decomposed so rapidly that a violent detonation is the consequence.

When heated in an open vessel, it gradually combines with oxygen, and evaporates in a white vapour. This vapour, when collected, constitutes a white coloured oxide, formerly called *argentine flowers of antimony*. When raised to a white heat, and suddenly agitated, antimony burns, and is converted into the same white coloured oxide.

III. Antimony has never been combined with carbon nor hydrogen. When its oxides are heated along with charcoal or oils, they are reduced, but imperfectly, unless some body, as potash, be present to favour the fusion of the metal. The greater part remains in a state of black spongy mass, which often takes fire when exposed to the air. Antimony combines readily with sulphur and with phosphorus.

Sulphuret of antimony may be formed by mixing its two component parts together, and fusing them in a crucible. It has a dark bluish gray colour, with a lustre approaching the metallic; it is much more fusible than antimony, and may be crystalized by slow cooling. It is composed, according to Bergmann, of 74 parts of antimony and 26 of sulphur. With this estimate the late experiments of Proust coincide almost exactly. According to that very accurate chymist, sulphuret of antimony is composed of

75.1 antimony.
24.9 sulphur.

100.0

This substance is found native in great abundance, and indeed is almost the only ore of antimony. It was to this sulphuret that the term *antimony* was applied by the earlier chymists; the pure metal was called *regulus of antimony*.

When equal parts of antimony and phosphoric glass are mixed together with a little charcoal powder, and melted in a crucible, phosphuret of antimony is produced. It is of a white colour, brittle, appears laminated when broken, and at the fracture a number of small cubic facettes are observable. When melted it emits a green flame, and the white oxide of antimony sublimes. Phosphuret of antimony may likewise be prepared by fusing equal parts of antimony and phosphoric glass, or by dropping phosphorus into melted antimony.

IV. Antimony does not combine with azote, nor with muriatic acid.

V. Antimony combines readily with most of the metals; but the greater number of its alloys have not been applied to any use. Antimony and gold may be combined by fusion, and form a brittle compound of a yellow colour. Great attention was paid to this alloy by the alchymists, who affirmed that the quantity of gold might be increased by alloying it with antimony, and then purifying it. Platina easily combines with antimony. The alloy is brittle, and much lighter than platina. The antimony cannot afterward be completely separated by heat. Silver may be alloyed with antimony by fusion. The alloy is brittle, and its specific gravity, as Gellert has observed, is greater than intermediate between the specific gravities of the two metals which enter into it. Antimony does not amalgamate with mercury while cold. When three parts of mercury are mixed with one part of melted antimony, a soft amalgam is obtained, which very soon decomposes of itself. Gellert also succeeded in forming this amalgam. Copper combines readily with antimony by fusion. The alloy, when it consists of equal parts of the two metals, is of a beautiful violet colour, and its specific gravity is greater than intermediate. This alloy was called *regulus of Venus* by the alchymists. Iron combines with antimony by fusion, and forms a brittle hard alloy, the specific gravity of which is less than intermediate. The magnetic quality of iron is much more diminished by being alloyed with antimony than with most other metals. This alloy may be obtained also by fusing in a crucible two parts of sulphuret and one of iron. It was formerly called *martial regulus*. The alloy of tin and antimony is white and brittle; its specific gravity is less than intermediate. This alloy is employed for different purposes; particularly for making the plates on which music is engraved. When equal quantities of lead and antimony are fused, the alloy is porous and brittle: three parts of lead and one of antimony form a compact alloy, malleable, and much harder than lead: twelve parts of lead and one of antimony form an alloy very malleable, and a good deal harder than lead: 16 parts of lead and one of antimony form an alloy which does not differ from lead except in hardness. This alloy forms printers' types. Its tenacity is very considerable, and its specific gravity is greater than the mean. Zinc may be readily combined with antimony by fusion. The alloy is hard and brittle, and has the colour of steel. Its specific gravity is less than intermediate. Antimony forms a brittle alloy with bismuth; to manganese it unites but imperfectly: the compounds which it forms with nickel and cobalt have not been examined.

VI. The affinities of antimony, and of its oxides, are, according to Bergmann, as follows:

Antimony.	*Oxide of Antimony.*
Iron,	Muriatic,
Copper,	Oxalic,
Tin,	Sulphuric,
Lead,	Nitric,
Nickel,	Tartaric,
Silver,	Saclactic,
Bismuth,	Phosphoric,
Zinc,	Citric,
Gold,	Succinic,
Platina,	Fluoric,
Mercury,	Arsenic,
Arsenic,	Lactic,
Cobalt,	Acetic,
Sulphur.	Boracic,
	Prussic,
	Carbonic.

ANTINOMIANS, in church history, certain heretics who first appeared about the year 1535; and so called, because they rejected the law, as of no use under the Gospel dispensation.

The name is now applied to a sect of high Calvinists, who sprung up in England about the time of Oliver Cromwell, and who are accused of maintaining that the elect are incapable of incurring guilt for whatever actual sins they may commit.

ANTIPATHES, the name of a genus in the zoophyta order of vermes: the character is, animal growing in the form of a plant; stem within horny, with small spines: base expanded, the outside covered with gelatinous flesh, and numerous polypiferous warts. There are several species, as spiralis, myriophylla, &c. See Plate, Nat. Hist. fig. 24.

ANTIPHONY, in music, the name which the Greeks gave to that kind of symphony which was executed in octave or double octave. It is likewise the answer made by one choir to another, when an anthem is sung between them.

ANTIPHRASIS, in rhetoric, a figure by which in saying one thing we mean the contrary.

This figure regards sentences, and not single words.

ANTIPODES, in geography, a name given to those inhabitants of the globe that live diametrically opposite to one another. They lie under opposite parallels, and opposite meridians. They have the same elevation of their

different poles. It is midnight with one when it is noon with the other; the longest day with the one is the shortest with the other; and the length of the day with the one is equal to that of the night of the other.

ANTIPTOSIS, in rhetoric, which puts one case for another.

ANTIQUARE, among Roman lawyers, denotes the rejecting a new law, or refusing to pass it.

ANTIQUARY, a person who studies and searches after monuments and remains of antiquity.

The Society of Antiquaries in London was instituted in the year 1751. Every member pays five guineas as an admission fee, and two guineas a year, or an additional sum of twenty-one guineas. They have weekly meetings every Thursday evening at their rooms in Somerset house. A similar society was founded in Edinburgh in 1780.

ANTIQUARY, is also used by ancient writers for the keeper of a cabinet of antiquities. John Leland was antiquary to Henry VIII.

ANTIQUE, in a general sense, something that is ancient; but the term is chiefly used by sculptors, painters, and architects, to denote such pieces of their different arts as were made by the ancient Greeks and Romans. Thus we say, an antique bust, an antique statue, &c. See SCULPTURE.

ANTIQUITIES. There is scarcely a term, perhaps, in any language so thoroughly comprehensive as that now before us: since it implies all testimonies or authentic accounts that have come down to us, which illustrate either the particular or universal history of ancient nations: a science equally complicated as extensive.

To enter elaborately into the subject would be to rewrite a hundred treatises: we must here content ourselves with an elementary survey; and without extending our views to those who have written on more trifling objects of inquiry, divide antiquities into two grand classes, political and monumental: the first forming a general, the other a particular study: the first embracing all that can increase our knowledge of civil institutions, the latter entirely confining itself to works of *art*; and, together, affording the most effectual means of learning the genius and manners of the various nations of the world. For the latter of these classes we shall refer to the respective arts whose investigation is concerned. But for the illustration of the former, we shall present a general view of ancient history, confining ourselves to those which may be deemed either leading, or the parent, countries of science, in the different periods: beginning our researches with the Jews, at a time when the history of every other country is involved in darkness and uncertainty; proceeding with the Egyptians and the Indians, the remnants of whose greatness preserve the earliest relics of profane history; following them up with the Greek and Roman antiquities; and concluding with the antiquities of Britain. On the Egyptian and Indian antiquities we shall be more circumstantial than on those of other countries; since their history and remains present a field of inquiry still open to investigation.

The history of a people persecuted and scattered through the world, yet whom no change of fortune has been able to eradicate, is a subject of consideration too deep and too important to leave a slight impression on the mind. But the history of the Jews has even more to boast: in the records of *their* nation they pass the general flood, the boundary to the annals of every other people; and fairly trace their ancestry back to the common father of the human race.

In the Bible we find the only authentic history of the origin, ordinances, and vicissitudes, of the nation: from that we learn, that their religious rites were divinely communicated. Unlike to every other people, they have remained distinct; and are continued so for greater ends than the meanness of their present state may seem to promise.

Could we ascertain the antiquities of Egypt with precision, those of the Jews might be expected thence to receive collateral illustration; since Moses, their great lawgiver, was confessedly educated in the schools of Egyptian learning and legislation: and many even of the metaphors he uses in the Pentateuch are supposed to bear some connection with objects or symbols communicated to him by the Egyptian priests.

To the more enlightened nations of antiquity, however, their history and their religious customs were equally unintelligible. The Greeks, by a fabulous tradition, deduced them from Jupiter and Saturn; and the Romans, till Tacitus's time, knew little of them. Tacitus indeed charges the whole nation with a sullen hatred of all mankind. In one or two cases he gives something that appears to border on the truth. But, in the general account, he relates the various opinions that were floating in the world, and leaves the truth to rest on better authority: apparently thinking that with regard to such a race minute inquiry was unnecessary. Though, at this period, the page of Jewish history was fully disclosed, and accessible to the curiosity of every Roman; Josephus lived at Rome, under Vespasian, Titus, and Domitian; and under the last of those emperors his Jewish Antiquities were given to the world.

A sufficient knowledge of the general antiquities of the Hebrews may be obtained from the Bible, Philo and Josephus, and the Talmud; and, among the writers of more modern date, Arias Montanus, Carpsovius, Maimonides, Buxtorf, Reland, Leusden, Calmet, Witsius, Bucher, Benzelius, Basnage, Hottinger, and Michaelis, may be deemed the best. Among the English, Selden, Godwyn, and Lewis. Calmet's Dictionary of the Bible also contains many references for the curious reader; and those who would know how far their ancient and modern practices agree, may consult Levi's Jewish Ceremonies.

On the civil history of the Jews, Josephus may be consulted: with Struckford, and Prideaux's Connections. On the life and death of Moses, however; on the Exodus of the Israelites, and their leaders; on the Jewish kings; the Babylonish captivity; and on the history and condition of the Jews in different countries subsequent to their dispersion; the writers are extremely numerous: and a complete catalogue of them may be found in Mensel's Bibliotheca Historica. On the destruction of Jerusalem, Josephus and Tacitus are the principal writers in repute. And for the history of the Jews in England, Tovey's work may be referred to.

But the most copious work on Jewish antiquities is Ugolinus's Thesaurus, in thirty-four volumes, folio; the first bearing the date of 1744, the last 1769; containing all the best works which, previously to that time, had appeared, on the manners, laws, rites, and institutions of the

Hebrews: amounting in number to no less than four hundred and eighty-eight distinct treatises.

The most curious collection of Hebrew manuscripts in this country which illustrate the *literary antiquities* of the Jews, may be found in the Bodleian Library at Oxford. Few of them, in point of age, run beyond eight hundred years; and the most ancient, we believe, were brought by Dr. Pococke from Constantinople.

We cannot close this part of our article without recommending to attentive perusal the late bishop Lowth's Lectures on the Poetry of the Hebrews, which afford a better view than any other work of the taste and learning of that extraordinary people.

We now come to the *Antiquities* of *Egypt*: a country once as remarkable for the scheme of its laws, and the dark oracles of its priests, as for the commerce of its cities, the grandeur of its buildings, and the fertility of its territory. The earliest nations of the world are emphatically described by Dr. White to have been fed with the produce of her soil, and enriched with the treasures of her wisdom; and not only the more civilized countries at the present day, but the Arabs and the Indians, still view the relics of her greatness with a reverential regard. In 1801, when General Baird led his army from the Red Sea, a party of Seapoys, who saw the hooded serpent upon one of the ancient monuments of Egypt, fell down and worshipped it.

The quarries of marble and porphyry of Upper Egypt furnished the principal materials with which the first inhabitants raised their most stupendous works of art. But whence their oracular intelligence was drawn, it is impossible to say. To Hermes Trismegistus, a sage as highly reverenced among them as Zoroaster was among the Persians, the Egyptians ascribed the inventions of chief use to human life; and like every people who are unable to settle the antiquity of their origin, they represented his works to have outstood the shock even of the universal deluge. They otherwise called him Thoth; and their priests as constantly maintained that from the hieroglyphic characters upon the pillars he erected, and the sacred books, all the philosophy and learning of the world have been derived.

Both the earliest and the latest writing of the country, to the time of Cleopatra, appears to have been symbolic; and the use of hieroglyphic characters was not only applied to sacred, but to other uses; through them alone the avenues to knowledge could be opened; and their secret appears principally to have lain in certain analogies and correspondences between the forms, actions, and qualities of animals, and certain facts in nature, morals or history. The animals which in the grosser periods of Egyptian history received the worship of the people, in the first ages it is probable were only used to express the attributes of the Egyptian gods; and their regard for them perhaps was much increased by their adherence to the doctrine of transmigration. A black ox, the symbol of the sun, was sacred to Osiris; and Isis typified the moon. Isis and Osiris indeed were every where adored, though differently represented; and the Mnevis, Apis, and Mendesian goat, are looked upon by the best writers but as different symbols of the same deity, or as animals in which the same deity was manifest. Thebes was in early times the grand deposite of Egyptian mystery: it is mentioned by Homer; and exists in ruins to the present hour. Dendera and Heliopolis present other ruins. To enter deeply here either into the particular ceremonies, or the mythological doctrines of Egypt, to seek for the phenomena of nature which were allegorized in the history of Isis and Orisis, or to detail the history of the priestly orders, would be impossible. Of the latter, the first after the inferior degrees was the chief of the music band, who usually carried some musical instrument as the ensign of his office; the next was the diviner, who in public processions bore the symbols of astrology; the third was the master of the sacred wardrobe; and the fourth, or chief priest, was the prophet, who interpreted the laws of Hermes, and presided over the ceremonies of religion. To these exclusively the Hermaic doctrines were accessible: and upon them the constitution of their country seems entirely to have depended.

In regard to Egyptian history, its early chronology is so perplexed, its facts and fable so heterogeneously blended, and its vanity of a remote antiquity so great, that little certain can be collected. Egypt was anciently divided into three parts. Thebais was a distinct district; the dynasty of Memphis was the *upper* Egypt; and that of Heliopolis, comprehending the rest of the Delta, the *lower* region. From Menes the Egyptian priests were accustomed to reckon no less than three hundred and thirty kings. Like other states, however, it had its revolutions; and the three districts did not in every period of its history form separate states. Under the shepherd kings, two of them were united. At a period considerably lower, Egypt became a kingdom still more flourishing than ever; and increased gradually till Sesostris, one of the greatest of its sovereigns, erected an universal empire. At a period still more subsequent, it was subjected by Cambyses to the *Persian* empire; and to his ravages it appears that Egyptian grandeur was principally indebted for its fall.

In the wreck of greatness which it still presents, the following are the principal remains: the colossal sphinx, and the pyramids among the level plains by Memphis; the statues which bear the name of Memnon; the catacombs of Saccara; the temples of Thebes, Tentyris, and Apollinopolis; and the Needle of Cleopatra. Pompey's Pillar is undoubtedly a monument of subsequent erection. One or two of the ancient obelisks were transported to Italy at a very early period. But the finest remnants of Egyptian grandeur, which have been brought away of late years, are now in the metropolis of England. The sarcophagus of brecciated marble, reputed to be Alexander's tomb; and the triple inscription from Rosetta, in the hieroglyphic, the vernacular Egyptian, and the Greek characters; are undoubtedly the most curious. The latter, when in possession of the French, was termed the gem of antiquity.

To recite even the titles of the different works in which the antiquities of Egypt have been treated, would be endless. Among the ancient writers, Herodotus, Pausanias, Strabo, Diodorus Siculus, and Plutarch, are the principal. Herodotus, Thales, and Pythagoras, it will be remembered, were initiated among the Egyptian priests. The best work on the mythology of Egypt is Jablonski's Pantheon Egyptiacum. On its present remains, Pococke, Norden, Niebuhr, Sonnini, and Denon, may be consulted: Greaves and Norden have expressly written on the pyramids·

Kircher on the mummies: and all that is material on the subject of the obelisks, may be found in Zoega De Obeliscorum Usu. In the simple and authentic narrative of Dr. Whitman, modern readers will find some facts worthy of their attention, relative to the monumental remains still existing in Egypt.

For the illustration of the ANTIQUITIES OF INDIA our accessible materials are less numerous and less distinct. The light which so strongly radiates from the page of classical antiquity upon most other abstruse points of literary research, casts but a glimmering ray on this subject. Whatever genuine information may be obtained on other points, its early history and literature can only be acquired by the generality of readers through the medium of faithful versions from the Sanscreet, the ancient original language of the country, and the grand repository of all its history and sciences.

So long ago as 1776, Mr. Halhed, in the Code of Gentoo Laws, compiled under the direction of Mr. Hastings, gave the first specimen which appeared of the early wisdom of the Indians, and their extensive skill in jurisprudence. But the attention of the world was principally roused by the publication of the Bhagvat Geeta, edited in 1785 by Mr. Wilkins. It was the episode only of a larger poem; but its theological and metaphysical doctrines were of the profoundest kind: it was represented to contain all the grand mysteries of the Hindoo religion; and laid claim to the venerable antiquity of four thousand years. The Hectopades, the Sacontala, and Ayeen Akbery, were the principal succeeding publications; the lights from which, added to those of the Asiatic Researches, occasioned Mr. Maurice to give the antiquities of India a more deep and elaborate investigation than they ever had received before. Till this book appeared, the antiquities of the Hindoos were considered by the generality of readers as unfathomable; and by the skeptical philosopher as affording arguments in respect to the age of the world, which struck at once at the root of the Mosaic system. With these authorities in hand, Mr. Maurice proceeded to elucidate the obscure history of the Avatars, or the ten descents of Veeshnu. The persons who are stated by the Indian writers to have flourished so many thousand years in the earliest ages, he supposes to have been not of terrestrial but celestial origin; and that their empire was rather the empire of imagination in the skies than that of real power on the earth. He considers that the year of ordinary reckoning, and the year of Brahma, are of a nature very widely different; and that the whole jargon of yugs, or grand periods, has no foundation but in the great solar and lunar cycles, or planetary revolutions. In the Indian Antiquities the greater part of the preliminary ground, which the student must of necessity go over, is cleared. The ancient geographical divisions of India, according to the classical writers of Greece and Rome, and of Hindostan, according to the Hindoos themselves, are reconciled: the analogies of the Brahmanic with other systems of theology considered; and the grand code of civil laws, the original form of government, and the various and profound literature of Hindostan, are compared throughout with the laws, government, and literature, of Persia, Egypt, and Greece.

But after all, perhaps, the clearest notions of what the student may expect to discover in his Indian inquiries, may be gathered from the few papers published in the Asiatic Researches, by sir William Jones; written in consequence of the institution of a society for inquiring into the history, civil and natural, the antiquities, arts, sciences, and literature, of Asia.

His first dissertation was on the orthography of Asiatic words in Roman letters, a want of attention to which had occasioned great confusion in history and geography; and he proposed a system, which was not only at once useful to the learned, and essential to the student, but the convenience of which had been proved by careful observation and long experience. The gods of Greece, Italy, and India, were the next objects of attention; and in this dissertation the general union or affinity between the most distinguished inhabitants of the primitive world in regard to theological concerns, at the time when they first deviated from the rational adoration of the true God, is inferred. The general character and affinities of the ancient pantheon of India are considered with the best attention. Gané-a, the Hindoo divinity of Wisdom, is compared with the Janus of the Romans; Menu, or Satyvrata, whose general history bears a strong resemblance to Noah's, with Saturn; the Lachsmi of the Hindoos, or goddess of Abundance, with Ceres; and Zeus, or Jupiter, in his various capacities, compared with the triple divinity Veeshnu, Siva, Brahma. Others of minor consideration are also fully noticed, the explanation of whose various attributes must be sought for in the dissertation itself: in which it seems to be fairly proved, that a connection subsisted between the old idolatrous nations of Egypt, India, Greece, and Italy, long before they migrated to their several settlements, and consequently before the birth of Moses: a proposition, says sir William Jones, which will in no degree affect the truth and sanctity of the Mosaic history.

From Goverdhan Caul, the society already mentioned received a valuable communication on the *literature* of the Hindoos, from a work in the Sanscrit. It was translated, and a commentary added. In the text, the Vedas are considered by the Hindoos as the fountain of all knowledge human and divine; and the commentary concludes with this remarkable expression, that if Europeans wish to form a correct idea of Indian religion and literature, let them begin with forgetting all that has been written on the subject by ancients or moderns, before the publication of the Gità.

From sir William Jones's fourth anniversary Discourse, delivered to the Asiatic Society in 1786, we may form some notion of the various discoveries to which future exertions may give rise, not only in the literature, but the history, sciences, and arts of Asia.

India on its most enlarged scale, in which the ancients appear to have understood it, comprises an area of near forty degrees on each side; it is divided on the west from Persia by the Arachosian mountains; limited on the east by the Chinese part of the further peninsula; confined on the north by the wilds of Tartary; and extending to the south as far as the isles of Java. By India, in short, is meant that whole extent of country in which the primitive religion and language of the Hindoos prevail at this day with more or less of their ancient purity; and in which the Nágarì letters are still used with more or less deviation from their original form. Its inhabitants have

no resemblance either in their figure or manners to any of the nations contiguous to them; their sources of wealth are still abundant: in their manufactures of cotton they surpass all the world; and though now degenerate and abased, there remains enough to show that in some early age they were splendid in arts and arms, happy in government, wise in legislation, and eminent in various knowledge. The Sanscrit *language*, whatever may be its antiquity, is of a wonderful structure; more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could possibly have been produced by accident. The *characters*, as we have already mentioned, are Nagari. Of the Indian *religion* enough has been already said. Of their *philosophy*, sir William Jones observes, that in the more retired scenes, in groves and in seminaries of learning, we may perceive the Brahmans and the Sarmanas of Clemens disputing in the forms of logic, or discoursing on the vanity of human enjoyments, on the immortality of the soul, her emanation from the eternal Mind, her debasement, wanderings, and final union with her source. The *six* philosophical schools, whose principles are explained in the Dersana Sástra, comprise all the metaphysics of the old Academy, the Stoa, the Lyceum: nor is it possible to read the Védantá, or the many fine compositions in the illustration of it, without believing that Pythagoras and Plato derived their sublime theories from the same fountain with the sages of India. The remains of *architecture* and *sculpture* seem to prove an early connection between India and Africa. Of their ancient *arts* and *manufactures*, little but the labours of the Indian *loom* and *needle* are at this day known; but from a curious passage in one of their sacred law tracts relating to the extraordinary interest of money, in regard to *maritime* concerns, it should seem that they were in the early ages a *commercial* people. The Hindoos are said to have boasted of three inventions, all of which are indeed admirable; the method of instructing by *apologues*, *the decimal scale*, and the game of chess: and could their numerous works on grammar, rhetoric, and music, which are now extant, be explained in some language generally known, it would be found that they had still higher pretensions to the praise of a fertile and inventive genius. Their lighter *poems* are lively and elegant; their epic magnificent and sublime. Their most ancient *medical* book, entitled Chereca, is believed to be the work of Siva: for each of the divinities in their triad has at least one *sacred* composition ascribed to him. On *history* and *geography* their works are few; and their *astronomical* and *mathematical* writings are still secret.

Cursory as the observations are which have been here brought together, their expansion and illustration would require volumes.

Of the Avatars, or descents of the Deity in his capacity of preserver, we have little to say. The three first, says sir William Jones, apparently relate to some stupendous convulsion of our globe from the fountains of the deep; and the fourth exhibits the miraculous punishment of pride and impiety. The three first, he thought, related to the same event, shadowed by a moral, a metaphysical, and an astronomical allegory; and all three, connected with the hieroglyphical sculptures of the old Egyptians. The fourth avatar was *a lion* issuing from a bursting column of marble to devour a blaspheming monarch, who would otherwise have slain his religious son; and of the remaining six he says, not one has the least relation to the deluge. The tenth avatar, we are told, is yet to come; and is expected to appear mounted, like the crowned conqueror in the Apocalypse, on a white horse, with a cimeter blazing like a comet to mow down all incorrigible and impenitent offenders who shall be then on earth.

Among the most curious of the existing monuments of ancient India, we must reckon the sculptures and ruins of Mavalipuram, a few miles north of Sadras, and known to seamen by the name of the Seven Pagodas; the vast excavations of Canarah; the various temples and images of Buddha; and the idols which are continually dug up at Gayá, or in its vicinity.

The principal of the Hindoo excavations have been engraved and published by Mr. Daniel; and deserve the closest attention from all who are studious of the antiquities of India.

"The first accounts of Greece," says Mr. Mitford, "are derived from ages long before the common use of letters in the country." But so mysterious are the ages of antiquity, and so precarious are traditions, that we scarcely know by what method to distinguish where fable concludes, or truth begins. Certain however it is, that from the Phenician and Egyptian colonies the Greeks first received the culture of humanity. By the Phenicians they were undoubtedly instructed in trade, navigation, and the use of letters; and by the Egyptians in civil wisdom, the politer sciences and religious mysteries. The antiquities of such a country then, which was afterward so singularly illustrious in the annals of mankind, the introduction of its institutions, and the invention or introduction of its arts, must surely carry with them an interest still more striking than those either of Egypt or India. Its antiquities, of course, in every accessible period have been more carefully and more minutely inspected; and have received such deep and extensive investigation, that to attempt a summary here would be impossible. We shall only observe, that the Athenians were the first civilized people of Greece; and that in all the greatness of the Grecian states they still retained the highest polish.

Gronovius has given a collection of the chief writers on the antiquities of Greece, to which we shall refer the reader once for all; and Rouse, Pfeiffer, Bos, and bishop Potter, have given shorter systems; the last of which is certainly esteemed the best, and which no scholar's library should be without. In what relates to the religion, the gods, vows, and temples of Greece, it has been deemed too summary; but in the military affairs and miscellaneous customs it remained till lately without a rival. A work which supersedes it, and perhaps all others in the English language, for accuracy and completeness, has just made its appearance from the pen of Mr. Robinson of Ravenstondale.

On the gods, temples, oracles, and priests of Greece, the writers are extremely numerous: on the public weal and magistracy of Greece, Stephanus, Laurentius, and Van Dale, of modern writers, have perhaps the greatest share of credit; on the court of Areopagus, Meursius, and Freher; on the laws and punishments of Greece, Prateius, Meursius, and Petit; on military concerns, Arrian, Polyænus, and Ælian; on the gymnastic art, and

exercises of the Greeks, Hieronymus Mercurialis, Joubert, Faber, and Burette; on the theatres and scenic exhibitions, Donatus, Scaliger, Brindin, and the abbe Barthelemy; on their entertainments, luxury and baths, Cornarius, Meusonius, Gedoyn, Du Choul, Ferrarius, and Kuhn; on their marriages and institution of their children, besides the general writers, Hauptmann, Junius, Stisser, and Zeibich, are the more particular; and on their funerals, Nicolai, Langius, and Eckhard.

The best relics which still mark the former splendour of the Grecian states have been preserved by Stuart in his Athens; in the Ionian Antiquities, published under the direction of the Dilettanti society; in the Voyage Pittoresque de la Grece; and in the Museum Horsleyanum. The best relics of its sculpture in this country are to be found among the Townley marbles; and of its beautiful coinage, in the cabinet of Dr. Hunter.

Poetry, sculpture, architecture, and painting, perhaps attained the summit of perfection under the respective cultivation of Homer, Phidias, Praxiteles, and Zeuxis.

Nothing, says Dr. Adams, has more engaged the attention of literary men, since the revival of learning, than to trace from ancient monuments the rights and customs of the Romans, comprehended under the general name of Roman Antiquities. This branch of knowledge, he observes, is not only curious in itself, but absolutely necessary for understanding the classics, and for reading with advantage the history of that celebrated people. And it is particularly requisite for such as prosecute the study of the civil law.

Scarcely on any subject have more books been written, and many of them by persons of the most distinguished credit. Among the oldest of the good writers may be reckoned Dionysius Helicarnassus, who traced the origin of the Romans, with the utmost fidelity, back to the remotest ages. His accounts are generally preferred to Livy's. They are more ample, and his facts described with more particulars; and on their ceremonies, worship, sacrifices, manners, customs, discipline, policy, courts, laws, &c. he is perhaps the most authentic writer.

A body of the authors on the Roman antiquities was published by Grævius in the Thesaurus; and Danet and Pitiscus published lexicons of them. For the most part however they are too voluminous, not only to be generally useful, but even to refer the studious reader to, except on single points. On this account a number of abridgments have been published; of which, till of very late years, those of Kennet and Nieuport were esteemed the best. The latter was written in Latin, but it abounded in difficult phrases, and was deficient in one or two material parts, which were supplied by Kennet. Both, however, have been since superseded by the work of Dr. Adams, which of all the abridgments is the best adapted to illustrate the classics. It is sufficient to say that he has borrowed with freedom from all hands whatever he judged fit for his purpose; and the enumeration of his sources will prove the best aid to an inquiring reader. He was chiefly indebted to Manutius, Brissonius, and Middleton, on the senate: to Pignorius on slaves; to Sigonius and Grucchius, Manutius, Huber, Gravina, Merula, and Heineccius, on the assemblies of the people, the rights of citizens, the laws and judicial proceedings; to Lipsius on the magistrates, the art of war, shows of the circus, and gladiators; to Sheffer on naval affairs and carriages; to Ferrarius on the Roman dress; to Kirkmannus on funerals; to Arbuthnot on coins; to Dickson on agriculture; to Donatus on the city; to Turnebius, Abrahamus, Rossinus Salmesius, Hottomanus, Grævius and Gronovius, Montfaucon, Pitiscus Ernesti, and particularly Gesner, in different parts of the work.

On the antiquities of ancient Rome, the works of Publius Victor, Fulvius, Fabricius, Onuphrius Panvinius, Boissard, and Adler, are perhaps the best: on its ancient edifices, the work of Desgodetz, in which the views are given from actual measurement; Venuti's Descrizione Topografica delle Antichita di Roma; and D'Overbeke's Restes de l'Ancienne Rome: on its public ways its walls, aqueducts, and bridges, Bergier, Gautier, and D'Anville, may be referred to: while the statues and other works of art with which Rome and her provinces abonnded have frequently furnished subjects for separate disqnisitions.

The arts it should seem in the best periods of the Roman history flourished in the greatest perfection at Rome; where the specimens which remain are still viewed with singular veneration. Among the best of them are the columns of Antoninus and Trajan; the statue of Marcus Aurelius; the arches of Septimius Severus and Constantine; the amphitheatre; the theatre of Marcellus; and the different baths. The columns of the temple of Concord are the only eminent specimens in Rome of the Ionic order, where the volutes of the capital stand in a diagonal direction; and the first and purest specimen of the Corinthian order is exhibited in the three columns of the campo vaccino, supposed to have belonged to the temple of Jupiter Stator.

A correct view of the Antiquities of Britain from the earliest period to the end of Henry the Eighth's reign, may perhaps be best collected from Dr. Henry's History. The writers he refers to will present the reader with all the most authentic sources of inquiry.

Of what relates to the early Britons, however, much that has been written is two nearly connected with the fabulous; and instead of seeking for information on Druidical history, where it was most likely to be obtained correctly, the generality of our writers have been too apt to busy themselves with theory and etymology. "Druidism," says one, "was palpably *Phenician*. The Druidical system was taught the Gauls by *Pythagoras!*" The opinion, however, which in Cæsar's time was generally entertained in Gaul, has been overlooked. Cæsar evidently took considerable pains to learn every particular relating to the Druids; and he states it to have been the received opinion that Druidism originated in Britain. And in corroboration of this idea, it has been both strongly and correctly urged, that there is not a single authority for the existence of Druidism any where but in Celtic Gaul and part of England. Cæsar, however, did not himself witness its existence in Britain: Tacitus is the first, and, we believe, the only author who notices it; for the Romans did not meet with it till they had advanced far into Wales. Cæsar, Dio Cassius, and Tacitus, are the principal authorities in regard to British *history*. On the religious system, and the mysteries of *Druidism*, the writers are more numerous; but Cæsar, Diodorus Siculus, Ælian, Strabo, Tacitus and Pliny, are perhaps the most

valuable of the ancients. Cluverius's Germania Antiqua, and the works of Pezron and Pelloutier upon the Celts, are however more recent authorities.

Of the structures which the Britons erected, the remains are few: Abury and Stonehenge may be deemed the principal. On the vast tracts of solitary down with which our island abounds, relics of a smaller kind are continually discovered. Rowbright in Oxfordshire affords the best, perhaps; and they are very numerous in Anglesey. On these Stukeley and Rowland are perhaps the best authorities: for the history of the Britons under the *Roman* government, we refer to Horsley's Britannia Romana. Antonine's Itinerary preserves the names of the towns and stations on the Roman military ways, with the number of miles between each town.

On the *antiquities* of our *Saxon* ancestors there is more to say; and we can trace their history with tolerable certainty. The devastations of the Danes, however, proved a great destruction to their monuments; and though the Normans were the descendants of the same ancestors, they were not less injurious to the institutions of the people who had gone before them. The best of their remains of art were evidently fabricated upon Roman models. Their architecture exhibited, as its leading feature, a bad imitation of the Roman arch; and their coins had *Latin* inscriptions. The little science they possessed during the middle and latter periods of their existence, though originally perhaps obtained from abroad, was cultivated with uncommon zeal: and Alcuin, Bede, and Alfred, are names in the history of their literature that will never be forgotten. The illuminations of the Saxon manuscripts are the best records of their manners in the different centuries; and the most curious information relating to them will be found in the elaborate works of Mr. Strutt and Mr. Turner. In this branch of our antiquities the field of investigation is still open. They have never yet been viewed upon that enlarged scale on which they deserve to be considered. The best collection of Saxon coins is that which is now deposited in the British Museum. Their remains of art are numerous, but for the most part undecided: the Normans having imitated their exertions with little other difference than an occasional enlargement of the scale. Of Saxon *manuscripts*, the best collection will be found in the library of the British Museum, and in the Bodleian Library at Oxford. Mr. King has treated their military antiquities in his History of Castles, and Dr. Hickes's Thesaurus may be viewed as the grand repository of their general literature.

Of the English nation at nearer periods, our documents, as may be naturally expected, occur in still greater variety. There is scarcely a county history but sets our ancient manners in new points of view. They have been often and systematically treated; and the names of Camden, Henry, Strutt, and Gough, are sufficient to be noticed.

Thus much may suffice as an outline of the national antiquities of the more considerable people of the world, though there is scarcely a nation under heaven but lays claim to a greater degree of antiquity than the rest of its neighbours. The Scythians, the Phrygians, the Chaldeans, Egyptians, Greeks, and Chinese, pretend each to have the honour of being the first inhabitants of the earth; and even so far have folly and etymology in these researches borne each other company, that Goropius Becanus asserted *high Dutch* to have been the primitive language of the world.

To go further in this extensive science here, or to treat every class of antiquities which writers have separately considered, would be endless. Reland has expressly treated on *sacred* antiquities; Fabricius on *Hebrew* and *ecclesiastical* antiquities; Bingham on *Christian* antiquities; bishop Stillingfleet on the antiquities of the British churches; Cave on *apostolical* antiquities; Consingicus on *academical;* Heineccius on such of the *Roman* as illustrated the civil law; Mallet on *northern*, and bishop Kennet on *parochial* antiquities. Under the title of antiquities however, it may be proper we should notice that industry has sometimes been exerted upon the pettiest trifles; and not unfrequently on objects the most frivolous and absurd.

ANTIRRHINUM, SNAPDRAGON, or CALVES SNOUT: a genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The essential characters are these: the calyx consists of five leaves: the basis of the corolla is bent backward, and furnished with pectoria; the capsule is bilocular. There are 52 species of the antirrhinum; the most remarkable are:

1. Antirrhinum arvense, the corn blue toad flax.
2. Antirrhinum cymbalaria, the ivy leaved toad grass.
3. Antirrhinum elatine, the sharp pointed fluellin.
4. Antirrhinum linaria, the common yellow toad flax. It is said to be cathartic and diuretic, but is not used in the shops.
5. Antirrhinum majus, the greater snapdragon.
6. Antirrhinum minus, the least toad flax.
7. Antirrhinum monospermum, the sweet smelling toad flax.
8. Antirrhinum orontium, the least snapdragon.
9. Antirrhinum repens, the creeping toad flax.
10. Antirrhinum spurium, the round leaved fluellin.

The snapdragon is an old inhabitant of our gardens, and we have hardly yet a more beautiful flower. The scarlet and crimson kinds are particularly ornamental, especially upon walls, where they will thrive best.

ANTI-SABBATARIANS, a modern religious sect, who oppose the observance of the Christian sabbath.

ANTISCII, in geography, people who live on different sides of the equator, whose shadows at noon are projected opposite ways: the people of the north are antiscii to those of the south.

ANTISEPTICS, among physicians, a denomination given to all substances that resist putrefaction.

Concerning these, which are extremely numerous, we have several curious observations in sir John Pringle's Diseases of the Army. The following table exhibits a comparative view of the antiseptic virtue of salts, the common sea salt being reckoned equal to unity.

Sea salt	1	Saline mixture	3
Sal gemmæ	1	Nitre	4
Tartar vitriolat.	2	Salt of hartshorn	4
Spirit. minder.	2	Salt of wormwood	4
Tartar solub.	2	Borax	12
Sal diuret.	2	Salt of amber	20
Sal ammoniac.	3	Alum	30

Some resinous, and other substances, were found to be twelve times more antiseptic than sea salt: such are myrrh, asafœtida, snakeroot, pepper, ginger, saffron, contrayerva root, &c.

ANTISPASMODICS, medicines proper for the cure of spasms and convulsions. See MATERIA MEDICA.

ANTISTASIS, in oratory, a defence of an action, from the consideration that if it had been omitted, worse would have ensued.

ANTISTROPHE, among lyric poets, that part of a song and dance in use among the ancients, which was performed before the altar, in returning from west to east, in opposition to strophe.

ANTITACTÆ, in church history, a branch of gnostics, who held that God was good and just, but that a creature had created evil; and, consequently, that it is our duty to oppose this author of evil, in order to avenge God of his adversary.

ANTITHESIS, in rhetoric, a contrast drawn between two things, which serve as shades to set off the opposite qualities of each other.

ANTITRAGUS, or ANTITRAGICUS musculus, in anatomy, a muscle of the ear.

ANTLER, among sportsmen, a start or branch of a deer's attire.

ANTOECI, in geography, an appellation given to those inhabitants of the earth who live under the same meridian, but on different sides of the equator, and at equal distances from it. The antoeci having the same longitude, and equal degrees of latitude, one north and the other south: their hours of day and night are the same, but they have opposite seasons, of course the longest day to the one is the shortest to the other.

ANTONOMASIA, in rhetoric, a figure by which the proper name of one thing is applied to several others; or, on the contrary, the name of several things to one. Thus we call a cruel person a Nero; and we say the philosopher, to denote Aristotle.

ANTRUM, among anatomists, a term used to denote several cavities of the body: as the antrum genæ, or that in the cheek bone. See ANATOMY.

AORIST, among grammarians, a tense peculiar to the Greek language, comprehending all the tenses; or rather expressing an action in an indeterminate manner, without any regard to past, present, or future.

AORTA, in anatomy, called also arteria magna, a large artery arising with a single trunk from the left ventricle of the heart above its valves, called semilunares, which serves to convey the mass of blood to all parts of the body. See ANATOMY.

AOUTA, the name of the paper mulberry tree at Otaheite, from which cloth is manufactured and worn by the principal inhabitants. The bark of the trees is stripped off, macerated and reduced to a fine pulp: it is then drained, and the fibres will adhere together in a piece. It is afterward to be beaten till it becomes as thin as muslin, when it is dyed red or yellow.

APACTIS, in botany, a genus of the dodecandria monogynia class and order. The essential character is, corolla four petalled: calyx none. There is only one species, a tall tree, a native of Japan.

APANAGE, or APENNAGE, in the French customs, lands assigned by a sovereign for the subsistence of his younger sons.

APARGIA, a genus of the class and order syngenesia polygamia æqualis. The essential character is, calyx subimbricate, with linear, parallel, unequal scales; down plumose, subsessile; recept. naked, subvillose. There are seven species, much resembling the dandelion, with which they were formerly confounded.

APATIT, a mineral divided by the German mineralogists, into two varieties, the crystalized and earthy. It is the phospholite of Kirwan.

APATURIA, in Grecian antiquity, an Athenian festival kept in honour of Bacchus.

It was during this solemnity, that the young people were registered in the respective wards of their fathers.

APAUME, in heraldry, expresses a hand open and extended, so that the full palm appears, as is seen by the hand of Ulster, borne by the baronets of England.

APELLITES, Christian heretics in the second century, who affirmed that Christ received a body from the four elements, which at his death he rendered back to the world, and so ascended into heaven without a body.

APEPSY, in medicine, denotes crudity or a bad digestion, arising from a rawness of the stomach, and a want of concoction of the aliments. See MEDICINE.

APERIENTS, in the materia medica, an appellation given to such medicines as facilitate the circulation by removing all obstructions. See MATERIA MEDICA.

APERTURE, in geometry, the space between two right lines which meet in a point and form an angle.

APERTURE, in optics, a round hole in a turned bit of wood or plate of tin, placed withinside of a telescope or microscope, near to the object glass, by means of which more rays are admitted, and a more distinct appearance of the object is obtained. According to Huygens, the best aperture for an object glass of thirty feet, is as thirty to three; that is, as ten to one, so is the square root of the focal distance of any lens, multiplied by thirty, to its proper aperture. Mr. Auzout says, he found by experience, that the proper apertures of telescopes ought to be nearly in the subduplicate ratio of their length. It is certain that object glasses will admit of greater apertures, if the tubes are blackened withinside, and their passage furnished with wooden rings.

APERTURES, or APERTIONS, in architecture, are used to signify doors, windows, chimnies, outlets and inlets for light, smoke, &c. They ought to be as few in number, and as moderate in dimensions, as possible, and never made too near the angles of the walls.

APERTURA TABULARUM, in law books, the breaking open a last will and testament. See the article WILL, &c.

APERTURA FEUDI, in the civil law, signifies the loss of a feudal tenure, by default of issue to him to whom the feud was first granted.

APETALOUS, among botanists, an appellation given to such plants as have no flower leaves, or corolla.

APEX, in antiquity, the crest of a helmet, but more especially a kind of cap worn by the flamens.

APHÆRESIS, in grammar, a figure by which a letter or syllable is cut off from the beginning of a word.

APHANES, a genus of the monogynia order, and tetandria class of plants; and in the natural method ranking

under the 35th order, senticosæ. The essential characters are: the calyx is divided into eight parts; there is no corolla; the seeds are two and naked. There is only one species, *viz.*

Aphanes arvensis, or pensley piert, a native of England. It is common in corn fields. The stalks rise 5 or 6 together; the flowers are of a greenish white.

APHELIUM, or APHELION, in astronomy, is that point in any planet's orbit, in which it is furthest distant from the sun; being that end of the greater axis of the elliptical orbit of the planet, most remote from the focus wherein the sun is.

The times of the aphena of the primary planets, may be known by their apparent diameters appearing least; as also, by their moving slowest in a given time. They may likewise be found by calculation, the method of doing which is delivered in most astronomical writers.

APELLAN, the name of a bright star in Gemini.

APHIS, in entomology, the puceron, vine fretter, or plant louse, an extensive genus of the hemiptera order. The character is: beak inflected; sheath of five articulations, with a single bristle: antennæ setaceous and longer than the thorax; either four erect wings or none; feet formed for walking; posterior part of the abdomen usually furnished with two little horns. There are many species which infest an endless variety of plants, and it is probable that each species is particularly attached to one or a few kinds of vegetables only: on this account each kind has been usually named after the plants on which it feeds. The aphides are known by the indiscriminate name of plant lice; they abound with a grateful moisture, and are eagerly sought for by ants, and many other creatures, or they would become very probably more destructive to the whole vegetable creation than any other race of insects whatever. Linnæus enumerates 33 species.

The extraordinary nature of these insects has for some time past justly excited the wonder and attention of naturalists. They were ranked among the animals which had been classed with the true androgynes spoken of by Mr. Breynius, till Mr. Bonnet seemed to have cleared it up in the affirmative, by taking and shutting up a young aphis at the instant of its birth, in perfect solitude, which yet brought forth in his sight 95 young ones. The same experiment being made on one of the individuals of this family, soon after it was produced, the new hermit soon multiplied like its parent; and one of this third generation, in like manner brought up in solitude, proved no less fruitful than the former. Repeated experiments, in this respect, as far as the fifth or sixth generation, all uniformly presenting the observer with fecund virgins, were communicated to the Royal Academy of Sciences; when an unforeseen and very strange suspicion, imparted by Mr. Trembley to Mr. Bonnet, engaged him anew in a series of experiments. Mr. Bonnet therefore reared to the amount of the tenth generation of solitary aphides, and had the patience to keep an account of the days and hours of the births of each generation. In short it was discovered, that they are really distinguished by sexes; that there are males and females amongst them, whose amours are the least equivocal of any in the world: that the males are produced only in the tenth generation, and are but few in number: that these, soon arriving at their full growth, copulate with the females: that the virtue of this copulation serves for ten generations: that all these generations except the first, from the fecundated eggs, are produced viviparous; and all the individuals are females, except those of the last generation, as already observed. These circumstances have been confirmed by other naturalists. In particular, we have a curious and accurate detail of them by Dr. Richardson of Rippon, in the Philosophical Transactions, vol. xi. art. 22. the perusal of which we earnestly recommend to our readers.

APHORISM, a maxim or principle of a science, or a sentence which comprehends a great deal in a few words. The term is seldom used but in medicine and law.

APHRACTI, in the maritime affairs of the ancients, were open vessels without any decks.

APHRODISIA, in antiquity, festivals kept in honour of Venus, the most remarkable of which was that celebrated by the Cyprians.

APHRODITA, in zoology, one of the naked sea insects, of an oval shape, and aculeated, with a perforation in the middle of the back.

APHTHÆ, in medicine, small, round, and superficial ulcers, arising in the mouth. The principal seat of this disease, is the extremity of the excretory vessels, salival glands, and in short all glands that furnish a humour like the saliva, as the lips, gums, &c.

APHYA COBITES, in ichthyology, a species of gobius, called in English the sea loch.

APHYLLANTHES, LEAFLESS FLOWER, or BLUE MONTPELIER PINK: a genus of the monogynia order, belonging to the hexandria class of plants: and in the natural method ranking under the 5th order, tetrapetaloidæ. In character it differs not from the juncus or rush, but in having a calyx of six petals, whereas the juncus has no calyx. There is only one species; *viz.*

Aphyllanthes Monspeliensis, a native of France. The root consists of a number of slender fibres: the radical leaves are very numerous, two inches long. The stalk is round, smooth, without a joint or knot, naked, and tolerably firm; at its top stands a single and very beautiful blue flower, but for which it would be a rush.

APIARY, a place where bees are kept, which should be properly defended from high winds, as well as from poultry, hogs, &c. whose dung is extremely offensive to the bees.

APIS, the *bee*, in zoology, a genus of insects belonging to the order of insecta hymenoptera. The mouth is furnished with two jaws, and a proboscis infolded in a double sheath. The wings are four in number, the two foremost covering those behind when at rest; in the anus or tail of the female or working bees, there is a hidden sting. These insects are distinguished into several species, each of which has its peculiar genius, talent, manners, and disposition. Variety prevails in the order of their architecture, and in the nature of their materials. Some live in society, and share their toils; such are the common bee. Others dwell and work in solitude, building the cradles of their families, as the leaf cutter bee does with the rose tree leaf, the upholsterer with the gaudy tapestry of the corn rose, the mason bee with a plaster, the woodpiercer with sawdust. All are employed in their little hermitage, with the care of providing for their offspring. The species enumerated by Linnæus, are no fewer than fifty-five; of which the following are the most remarkable:

1. Apis *Brasilianorum*, or pale red hairy bee, with the basis of the thighs black. This is a very large bee, every where covered with a testaceous skin. It is a native of America.

2. Apis *cariosa* is a yellowish hairy bee; and the feet and front are of a bright yellow colour. It builds in the rotten trees of Europe.

3. Apis *centuncularis*, leaf cutter, or black bee, having its belly covered with yellow down. The nests of this species are made with leaves, curiously plaited in the form of a matt or quilt. There are several varieties of the leaf cutting bees, all equally industrious. They dig into the ground and build their nests, of which some have the form and size of thimbles inserted one within another, others the size and shape of goose quills. These nests are composed of pieces of leaves. Each sort of bees cuts into its own materials; some the rose tree leaf, others the horse chesnut. A careful observer may discover rose tree leaves, cut as with a pinking iron; and there he may procure himself the pleasure of seeing with what dexterity a bee, destitute of any mathematical instrument, cuts out a circular piece, fit to be either the bottom or the lid of one of those nests; others it cuts out into ovals and semi-ovals, which form the sides of the nests, into each of which it deposites one egg with ready prepared victuals.

4. Apis *dentata*, or shining green bee, with black wings, and a kind of teeth on the hind thighs. The tongue of this bee is as long as its body.

5. Apis *ferruginea*, or smooth black bee, with the feelers, mouth, belly, and feet, of an iron colour. This is a small bee, and supposed to be of an intermediate kind between the bee and wasp. It is a native of Europe.

6. Apis *florisomnis*, or black bee with a cylindrical incurvated belly, having two tooth like protuberances at the anus, and a kind of prickles on the hind legs. This bee sleeps in flowers; whence the name.

7. Apis *lapidaria*, or red hairy bee, with a yellow anus, builds in holes of rocks.

8. Apis *muscorum*, or yellow hairy bee with a white belly, builds in mossy grounds. The skill displayed by these builders is admirable. In order to enjoy the pleasure of seeing their operations, let a nest be taken to pieces, and the moss conveyed to a distance. The bees will be seen to form themselves into a chain, from their nest to the place where the moss has been laid. The foremost lays hold of some with her teeth, clears it bit by bit with her feet, which circumstance has also procured them the name of *carding bees*, then, by the help of her feet, she drives the unravelled moss under her belly; the second, in like manner, pushes it on to the third. Thus there is formed an uninterrupted chain of moss, which is wrought and interwoven with the greatest dexterity by those that abide by the nest; and that their nest may not be the sport of the winds, and may shelter them from rain, they throw an arch over it, which they compose with a kind of wax, which dissolved in oil of turpentine, may be used in taking off impressions.

9. Apis *rostrata* is distinguished by the upper lip being inflected and of a conical shape, and by the belly being invested with bluish belts. They build their nests in high, sandy grounds, and there is but one young in each nest.

10. Apis *terrestris* is black and hairy, with a white belt round the breast, and a white anus; it builds its nest very deep in the earth.

11. Apis *variegata:* the breast and belly are variegated with white and black spots; the legs are of an iron colour. In Plate VII. Nat. Hist. fig. 25. is represented the *hirsuta;* fig. 26 and 27 the *nidulans* with a section of their hive: and fig. 28, Plate X. represents the *apis socialis*.

12. Apis *violacea* is a red bee, and very hairy, with bluish wings. The violacea is said to perforate trees, and hollow them out in a longitudinal direction; they begin to build their cells at the bottom of these holes, and deposite an egg in each cell, which is composed of the farina of plants, and honey or a kind of gluten. Plate X. Nat. Hist. fig. 29.

13. Apis *mellifica*, the domestic honey bee. This wonderful insect requires a threefold description; under its various characters of queen bee, drone bee, and working bee; for though this last kind is, strictly speaking, the only honey bee, yet all the three kinds are found and seem to be necessary in every community or hive of bees. The drones may easily be distinguished from the common or working bees: they are both larger and longer in the body: their heads are round, their eyes are full, and their tongues short. The form of the belly differs from those of both queen and common bees; and their colour is darker than either. They have no sting, and they make a much greater noise when flying, than either the queen or the common bees; a peculiarity of itself sufficient to distinguish them. If a hive is opened in the beginning of spring, not a single drone will be found in it; from the middle of May till the end of June, there will be found commonly from 200 or 300 to 1000; but from August to the following spring it would be in vain to seek for them. They go not out till 11 in the morning, and return before six in the evening. But their expeditions are not those of industry. Their rostrum and feet are not adapted for collecting wax and honey, nor indeed are they obliged to labour. They only hover upon flowers to extract the sweets, and all their business is pleasure. Their office is thought to be to impregnate the eggs of the queen after they are deposited in the cells; and while their presence is thus necessary, they are suffered to enjoy life; but as soon as they become useless in the hive, the working bees declare a war of extermination against them. This war affects not only the drones already in life, but even the eggs and maggots in the drone cells; for after the season proper for increasing the number of bees is past, every vestige of the drones is destroyed, to make room for honey. Mr. Bonnet, however, one of the latest and best writers on the subject, doubts the long established doctrine of the fecundating powers of the drones. He urges the following, among many, arguments: "That the queen stands in no need of their assistance to fecundate or impregnate her, appears from this consideration; that she lays eggs, which produce young bees, without having had any previous communication with the drones. I will not, however, suppose that the drones are of no use in the hive; but that the queen lays eggs which produce young bees, without so much as seeing a drone, I can with the utmost confidence affirm. The advocates for the old doctrine, that the drones are males, allege, that they impregnate the queen, before their brethren kill them. According to this

theory, she should continue for no less a period than 7 or 8 months, with about 12,000 impregnated eggs in her ovarium, which would certainly make her appear very large during the whole of that period. But it is unnecessary to waste arguments in refutation of this doctrine, as I have repeatedly had queens breed and lay eggs, and those eggs become bees, although these queens were bred 7 months after all the drones were dead, and some weeks before any new ones were hatched. These experiments, I think, are sufficient to silence all the arguments advanced by the advocates for the drone system. Mr. Debraw, indeed, creates little drones, and gives them power to live all the year, and to impregnate the queen at pleasure. But as room does not permit me to narrate the experiments whereby he attempts to prove this, I shall content myself with stating his sentiments in as few words as possible. He asserts, that, besides the common large drones, which every person acquainted with bees, knows, at first sight, there is a small kind of drones, which are, to all appearance, like the common bees, there being no visible difference, except that they have no sting, which he discovers by immersion in water, and pressure. After relating an experiment on this head, he says, 'I once more immersed all the bees, of a small swarm, in water, and when they appeared to be in a senseless state, I gently pressed every one of them between my fingers, in order to distinguish those armed with stings from those that had none, which last I might suspect to be males. Of these I found fifty-seven exactly of the size of common bees, yielding a little whitish liquor on being pressed between the fingers.' In answer to this, I shall here narrate an experiment I made several years ago. On the 1st of Sept. 1788, I took all the bees out of a hive that was breeding very fast, and in which I found only four drones: these I killed. I put the bees into a hive that had nothing in it but empty combs. After waiting ten days, upon looking between the combs, I found maggots, newly sealed up, in the cells. I then took out all the bees, and shook them into a tub full of water, from which immersion I recovered them gradually, and while doing this, I pressed each bee individually, to try if I could discover any of those stingless little drones; but not one appeared, all of them having stings, to the number of three thousand. After this I searched the old hive I had taken them out of, and cut out all the combs that had eggs or young in them; among which I found some cells that had new eggs in them; others whose eggs were converted into a small worm, and other some with maggots in them. I then restored the queen and all the bees, putting them into the same hive again, but without leaving a single egg in it. During the succeeding 20 days, I inspected the hive, and found the bees, in fine weather, working with great alacrity, a sure sign that the queen was breeding again. After this, on turning up the hive, and cutting out one of the brood combs, I found new laid eggs in some of them; others containing maggots; besides some young bees, almost ready to emerge from their cells. I made another experiment, about the same time, upon a hive that had some brood combs, but had not had a large drone for several weeks preceding. This hive did not contain above five hundred bees, a circumstance that was in my favour; as being less numerous, the trouble was proportionally less. I carried the hive into a close room in my house, that not a single bee might escape me; but after repeating the former experiment of immersing them in water, recovering, and pressing them one by one, I found that every one of them had a sting.

"The queen," adds Mr. Bonnet, "is easily distinguished from all the other bees in the hive, by the form, size, and colour of her body. She is considerably longer, and her wings are much shorter in proportion to her body, than those of the other bees. The wings of both common bees and drones cover their whole bodies, whereas those of the queen scarcely reach beyond the middle, ending about the third ring of her belly. Her hinder part is far more tapering than those of the other bees: her belly or legs are yellower, and her upper parts of a much darker colour than theirs. She is also furnished with a sting, though some authors assert that she has none, having been induced to form this opinion, because she is extremely pacific; so much so, indeed, that one may handle her, and even tease her as he pleases, without provoking her resentment. For my part, I never can excite a queen bee to draw her sting, nor could I even get a sight of it, but when I pressed her body. A young queen is a great deal smaller in size than a full grown one, being not much longer than a common bee, and is therefore not so easily observed when sought for. When only three or four days old, she is very quick in her motions, and runs very fast; but when pregnant with eggs, she becomes very large, and her body is heavy. Almost all writers are of opinion that the queen lays three different kinds of eggs, *viz.* one kind for the production of a queen bee, another species for that of the working bee, and a third for producing the drones. It was also long a received opinion, that no queen could lay eggs that were capable of producing bees, without the assistance of drones. Schirach refutes this doctrine, and entirely denies such an use of the drones. He advances this opinion, that 'the queen lays eggs which produce young bees, without any communication with the drones; and affirms that all the working bees are females in disguise; every one of whom, in an early stage of her existence, was capable of becoming a queen; from a knowledge of which fact, swarms may artificially be obtained from the early months of spring, and in any succeeding month, even to November.' He asserts, which is indeed the grand and decisive proof, that 'the practice of this art, of raising artificial queens, has already extended itself through upper Lusatia, the Palatinate, Bohemia, Bavaria, Silesia, and several parts of Germany, and even of Poland."

These experiments were repeated by Mr. Bonnet, and the result of them is summed up in the following words:

"Having repeated the experiment again and again, I can now affirm, with the utmost confidence and certainty, that the common or working bees, are endowed with the powerful faculty of raising a queen bee from an egg in a common cell, when their community stands in need of one. Their method is this: they make choice of a common cell with an egg in it, and inject some white liquid matter from their proboscis, of a thickish substance. They then begin to build upon the edges of the cell, and enlarge it. On the third day it appears fairly on the outside of the comb, in the form of a royal cell, and may now be properly so denominated. On the fifth day, the cell being now great-

ly enlarged, and a great deal of the whitish matter thrown into it, the royal maggot appears in the form of a semicircle, not unlike a new moon, being biggest in the middle part, and small at each end. In this form it is to be seen for two days swimming on the top, and in the midst of the matter in the cell; and on the seventh day it is sealed up. During this period she undergoes various metamorphoses. I have opened the royal cell on the 10th day, and have found the maggot still on the top of the white liquor; and having taken it into my hand to show it to any friend, it would move for a short time, although at this period it had not the smallest resemblance to a bee, being still only a maggot. But on the 14th or 15th day, the metamorphosis is so complete, that instead of a gross white worm, it comes forth a charming young queen bee."

When a queen dies by any accident, the bees of her hive immediately cease working, consume their own honey, fly about their own and other hives at unusual hours, when other bees are at rest, and pine away if not soon supplied with another sovereign. Her loss is proclaimed by a clear and uninterrupted humming. This sign should be a warning to the owner of the bees to take what honey remains in the hive, or to procure them another queen. In this last case the flock instantly revives, and pleasure and activity are apparent through the whole hive. The dissection of the queen bee shows evidently that she lays many thousand eggs. It is computed that the ovaria of a queen bee contain more than 5,000 eggs at one time; and therefore it is not difficult to conceive that a queen bee may produce 10,000 or 12,000 bees, or even more, in the space of two months.

"The working, or common bee," says Mr. Bonnet, "is smaller than either the queen or the drone bee. They have four wings fastened to their middle part, by which they are not only enabled to fly with heavy loads, but to make those well known sounds and hummings to each other, which are supposed to be their only form of speech. They have also six legs fastened to their middle. The two foremost of these are the shortest, and with these they unload themselves of their treasures. The two in the middle are somewhat longer, and the two last are longest. On the outside of the middle joint of these last, there is a small cavity in the form of a marrow spoon, in which the bees collect by degrees those loads of wax they carry home to their hives: this hollow groove is peculiar to the working bee. Neither the queen nor the drones have any resemblance of it. Each foot terminates in two hooks, with their points opposite to each other; in the middle of these hooks there is a little thin appendix, which when unfolded enables the insects to fasten themselves to glass or the most polished bodies. This part they likewise employ for transmitting the small particles of crude wax which they find upon flowers, to the cavity in their thighs. The honey bladder is a reservoir, in which is deposited the honey that the bee sips from the cups of the flowers, after it has passed through the proboscis, and through the narrow pipes that connect the head, breast, and belly of the bee. This bladder, when full, is of the size of a small pea, and is so transparent that the colour of the honey can be distinguished through it. The sting is situated at the extremity of the belly, and the head or root of it is placed contiguous to the small bladder that contains the venom. It is connected to the belly by certain small muscles, by means of which the bee can dart it out and draw it in with great force and quickness. In length it is about the sixth part of an inch. It is of a horny substance; is largest at the root, and tapers gradually toward the point, which is extremely small and sharp; and when examined by the microscope, appears to be polished exceedingly smooth. It is hollow within like a tube, that the venomous liquor may pass through it when it strikes any animal, which it does the very instant that the sting pierces the skin, and insinuates itself into the wound, which proves mortal to many small insects, as well as to the bee herself when she leaves her sting in the wound; as it draws after it the bladder, and sometimes part of the entrails of the bee. These working bees may be said to compose the whole community, except in the season of the drones, which hardly lasts three months. During all the other nine months, there are no other bees in the hive, except them and the queen."

In the Philosophical Transactions, No. clxxii. vol. i. we have an account of a species of honey bee found in some parts of America, very different in form and manners from the common bee of Europe. Their combs are composed of a series of small bottles or bladders of wax, of a dusky brown or blackish colour; and each nearly of the size and shape of a Spanish olive. They hang together in clusters, almost like a bunch of grapes, and are so contrived that each of them has its aperture, while the bees are at work upon it; but as soon as it is filled with honey, this aperture is closed, and the bees leave it and go to work upon another vessel. Their lodgings are usually taken up in the hollow of an old tree, or in some cavity of a rock by the sea side. They are sagacious in choosing the most secure retreats, because their honey is so delicious a bait that they are hunted after by many animals; and they have no power of defending themselves, having no stings as our bees have. The combs are brittle, and the honey is clear and liquid like rock water. It is used by the natives rather as a drink with their food than as honey. They use it also in medicine as a purge, drinking half a pint of it in the morning fasting.

With regard to the age of bees, the drones live but a little while, being destroyed without mercy by the working bees, probably to save honey. As to the age of the working bees, writers are not agreed. Some maintain that they are annual, and others suppose that they live many years. Many of them, it is well known, die annually of hard labour; and though they may be preserved by succession in hives or colonies for several years, the most accurate observers are of opinion that their age is but a year, or no more than two summers at the utmost.

These industrious insects, Mr. Bonnet remarks, "have their vices as well as their virtues." The most savage Indian tribes do not wage more deadly wars, than the bees of different hives, and sometimes of the same hive, occasionally do. Their fighting and plundering one another ought chiefly to be imputed, as Mr. Thorley observes, to their perfect abhorrence of sloth and idleness, or to their insatiable thirst for honey; for when, in spring or autumn, the weather is fair, but no honey can be collected from plants, and is to be found only in the hives of other bees, they will venture their lives to get it there. Sometimes one of the queens is killed in battle. In this case the bees of both hives unite as soon as her death is generally known among them.

The command which some persons have obtained over bees is very extraordinary. Mr. Wildman, some years ago, surprised the whole kingdom. He caused swarms to light where he pleased almost instantaneously: he ordered them to settle on his head, then removed them to his hand, and commanded them to depart and settle on a window, table, &c. at pleasure. We subjoin this method of performing these feats, in his own words: "Long experience has taught me, that as soon as I turn up a hive, and give it some taps on the sides and bottom, the queen immediately appears to know the cause of this alarm; but soon retires again among her people. Being accustomed to see her so often, I readily perceive her at first glance; and long practice has enabled me to seize her instantly, with a tenderness that does not in the least endanger her person. When possessed of her, I can without injury to her, or exciting that degree of resentment that may tempt her to sting me, slip her into my other hand, and, returning the hive to its place, hold her there, till the bees missing her, are all on wing, and in the utmost confusion. When the bees are thus distressed, I place the queen wherever I would have the bees to settle. The moment a few of them discover her, they give notice to those near them, and those to the rest; the knowledge of which soon becomes so general, that in a few minutes they all collect themselves round her; and are so happy in having recovered this sole support of their state, that they will long remain quiet in their situation. Nay, the scent of her body is so attractive of them, that the slightest touch of her, along any place or substance, will attach the bees to it, and induce them to pursue any path she takes."

When the bees begin to work in their hives, they are said to divide themselves into four companies; one of which roves in the fields in search of materials; another employs itself in laying out the bottom and partitions of their cells; a third is employed in making the inside smooth from the corners and angles; and the fourth company brings food for the rest, or relieves those who return with their respective burdens. But they are not kept constant to one employment; they often change the tasks assigned them; those that have been at work being permitted to go abroad, and those that have been in the fields already, take their places. They seem even to have signs by which they understand each other; for when any one of them wants food, it bends down its trunk to the bee from whom it is expected, which then opens its honey bag, and lets some drops fall into the other's mouth, which is at that time opened to receive it. Their diligence and labour are so great, that, in a day's time, they are able to make cells, which lie upon each other, numerous enough to contain 3,000 bees.

As the combs would be apt, when full, to overcome by their weight all the security which the bees can give them against falling, those who prepare hives set in them crosswise, sticks, which serve as props to the combs, and save the bees great labour.

The habitations of bees ought to be very close; and what their hives want from the negligence or unskilfulness of man, these animals supply by their own industry. For this purpose they make use of a resinous gum, which is more tenacious than wax, and differs greatly from it. This the ancients called *propolis*. It will grow considerably hard in the hive, though it will in some measure soften by heat, and is often found different in consistence, colour, and smell. It has generally an agreeable aromatic odour when it is warmed; and by some it is considered as a most grateful perfume. When the bees begin to work with it, it is soft; but it acquires a firmer consistence every day, till at length it assumes a brown colour, and becomes much harder than wax. The bees carry it on their hinder legs; and some think it is met with on the birch, the willow, and poplar.

Bees anxiously provide against the entrance of insects into the hive, by gluing up with wax or propolis the smallest holes in it. Some stand as sentinels at the mouth of the hive, to prevent insects of any kind from getting in. But if a snail or other large insect should get in, notwithstanding all resistance, they sting it to death; and then cover it over with a coat of propolis, to prevent the bad smell or maggots which might proceed from the putrefaction of such a large animal.

Bees seem to be warned of the appearance of bad weather by some particular feeling. It sometimes happens, even when they are very assiduous and busy, that they on a sudden cease from their work; not a single bee stirs out; and those that are abroad hurry home in such prodigious crowds, that the doors of their habitations are too small to admit them. On such occasions, if we look up to the sky, we shall soon discover some of those black clouds which denote impending rain. So correct is their instinct, that it exceeds the sagacity of the philosopher.

When a hive of bees is become too much crowded by the addition of the young brood, a part of the bees think of finding themselves a more commodious habitation, and with that view single out the most forward of the young queens. A new swarm is therefore constantly composed of one queen at least, and of several thousand working bees, as well as of some hundreds of drones. The working bees are some old, some young. Scarcely has the colony arrived at its new habitation, when the working bees labour with the utmost diligence to procure materials for food and building. They make more wax during the first fortnight, if the season is favourable, that they do all the rest of the year. Other bees are at the same time busy in stopping all the holes and crevices they find in the new hive, in order to guard against the entrance of insects which covet their honey, their wax, or themselves; and also to exclude the cold air, for it is indispensably necessary that they be lodged warm. When the bees first settle in swarming, indeed when they at any time rest themselves, there is something very particular in the method of taking their repose. It is done by collecting themselves in a heap, and hanging to each other by their feet.

When a swarm divides into two or more bands, which settle separately, this division is a sure sign that there are two or more queens among them. One of these clusters is generally larger than the other. The bees of the smaller cluster or clusters detach themselves by little and little, till at last the whole, together with the queen, unite with the larger cluster. As soon as the bees are settled, the supernumerary queen or queens must be sacrificed to the peace and tranquillity of the hive. This execution generally raises a considerable commotion in the hive; and several other bees, as well as the queen, lose their lives. Their bodies may be observed on the ground near the

hive. The queen that is chosen is of a more reddish colour than those which are destroyed: so that fruitfulness seems to be a great motive of preference in bees; for the nearer they are to the time of laying their eggs, the bigger, redder, and more shining are their bodies.

The balls which we see attached to the legs of bees returning to the hives, are not wax, but a powder collected from the stamina of flowers, not yet brought to the state of wax. The substance of these balls, heated in any vessel, does not melt as wax would, but becomes dry, and hardens: it may even be reduced to a coal. If thrown into water it will sink; whereas wax swims. To reduce this crude substance into wax, it must first be digested in the body of the bee. Every bee, when it leaves the hive to collect this precious store, enters into the cup of the flower, particularly such as seem charged with the greatest quantities of this yellow farina. As the animal's body is covered over with hair, it rolls itself within the flower, and quickly becomes quite covered with the dust, which it soon after brushes off with its two hind legs, and kneads into two little balls. In the thighs of the hinder legs there are two cavities, edged with hair; and into these, as into a basket, the animal sticks its pellets. Thus employed, the bee flits from flower to flower, increasing its store, and adding to its stock of wax, until the ball upon each thigh becomes as big as a grain of pepper: by this time having got a sufficient load, it returns, making the best of its way to the hive. After the bees have brought home this crude substance, they eat it by degrees; or, at other times, three or four bees come and ease the loaded bee, by eating each of them a share, the loaded bee giving them a hint so to do. Hunger, however, is not the motive of their thus eating the balls of waxy matter, especially when a swarm is first hived; but it is their desire to provide a speedy supply of real wax for making the combs. At other times, when there is no immediate want of wax, the bees lay this matter up in repositories, to keep it in store; and it is then known by the name of bee bread.

It is agreed by the most judicious observers that the apiary, or place where bees are kept, should face the south, and be situated in a place neither too hot nor too much exposed to the cold; that it be near the mansion house, on account of the convenience of watching them; but so situated as not to be exposed to noisome smells, or to the din of men or cattle; that it be surrounded with a wall, which, however, should not rise above three feet high; that, if possible, a running stream be near them; or, if that cannot be, that water be brought near them in troughs; as they cannot produce either combs, honey, or food for their maggots, without water: and that the garden in which the apiary stands, be well furnished with such plants as afford the bees plenty of good pasture. Furze, broom, mustard, clover, heath, &c. have been found excellent for this purpose.

Hives have been made of different materials, and in different forms, according to the fancy of people of different ages and countries. Not only straw, which experience now proves to be rather preferable to every thing else, but wood, horn, glass, &c. have been used for the construction of them. Single box hives, however, when properly made, answer very well, and when painted last long. They have several advantages above straw hives: they are quite cleanly, and always stand upright; they are proof against mice; and are cheaper in the end than straw hives, for one box will last as long as three of them. They are, however, rather colder in winter; but a proper covering will prevent all danger from that quarter. Straw hives are easiest obtained at first, and have been used and recommended by the best of bee masters. If the swarm be early and large, it will require a large hive; but if otherwise, the hive should be proportionably less. If the bees appear to want more room, it can easily be enlarged, by putting a roll or two below it; but if it be heavy enough for a stock hive, it will do, although it should not be quite full of combs.

Any person, says Mr. Bonnet, who intends to erect an apiary, must take particular care to have it filled with proper inhabitants. He must be peculiarly attentive to this, as all his future profit and pleasure, or loss and vexation, will, in general, depend upon it. He must therefore pay the utmost attention to the choice of his stock hives; for the man who takes care to keep good stock hives will soon gain considerably by them; but he who keeps bad ones, will, besides a great deal of trouble, and little or no success, soon become a broken bee master. In September every stock hive ought to contain as much honey as will supply the bees with food till June following; and as many bees as will preserve heat in the hive, and thereby resist the severity of a cold winter, and act as so many valiant soldiers to defend the community from the invasions of foreign enemies in spring. They should be full of combs, and well stored with bees and honey, and should weigh at least 30lb. each; if heavier, so much the better; for light hives run a great risk of perishing by famine, unless the bees are supplied with food; whereas a well chosen hive of 30lb. weight, allowing 12lb. for the empty hive, bees, combs, &c. will contain 18lb. of honey, which will supply the bees with food till June: a time when, it may be presumed, they will find abundance of provisions for themselves among the flowers. When a choice can be obtained, the youngest hive should always be preferred, because old hives are liable to vermin, and other accidents. But although a hive should be four or five years old, it should not be rejected, if it possess these two essential qualities, plenty of bees, and abundance of honey.

Bees first swarm in May, or in the end of April, but earlier or later according to the warmth of the season. They seldom swarm before ten in the morning, and seldom later than three in the afternoon. We may know when they are about to swarm, by clusters of them hanging on the outside of the hive. But the most certain sign is, when the bees refrain from going into the fields, though the season be inviting. Just before they take flight there is an uncommon silence in the hive; after this, as soon as one takes flight, they all follow. Before the subsequent swarmings there is a great noise in the hive, which is supposed to be occasioned by a contest, whether the young or the old queen should go out. When the bees of a swarm fly too high, they will descend lower, upon throwing handfuls of sand or dust among them, which they probably mistake for rain. For the same purpose it is usual to beat on a kettle or frying pan: this practice may have taken its rise from observing that thunder, or any great noise, prompts bees in the fields to return home. As soon as the swarm is settled, the bees which compose it should be

got into a hive with all convenient speed, to prevent their taking wing again. If they settle on a small branch of a tree, easy to come at, it may be cut off and laid upon a cloth, the hive being ready immediately to put over them. If the branch cannot be conveniently cut, the bees may be swept from off it into the hive. Lodge but the queen into the hive, and the rest will soon follow. If the bees must be considerably disturbed in order to get them into a hive, the most advisable way is to let them remain in the place where they have pitched till the evening, when there is less danger of their taking wing. If it be observed that they still hover about the tree they first alighted upon, the branches may be rubbed with rue, elder leaves, or any other thing distasteful to them, to prevent their returning to it. The hive employed on this occasion should be cleaned with the utmost care, and its inside rubbed with fragrant herbs or flowers, the smell of which is agreeable to the bees, or with honey. The hive should not be immediately set on the stool where it is to remain, but kept near the place at which the bees settled, till the evening, lest some stragglers should be lost. It should be shaded either with boughs or with cloth, that the too great heat of the sun may not annoy the bees. We sometimes see a swarm of bees, after having left their hive, and even alighted upon a tree, return to their first abode. This never happens but when the young queen did not come forth with them, for want of strength, or perhaps courage to trust to her wings for the first time; or possibly from a consciousness of her not being impregnated.

When a swarm is too few in number for a hive, another may be added. The usual method of thus uniting swarms is very easy. Spread a cloth at night upon the ground close to the hive in which the two casts or swarms are to be united; lay a stick across this cloth; then fetch the hive with the new swarm, set it over the stick, give a smart stroke on the top of the hive, and all the bees will drop down upon the cloth in a cluster. This done, throw aside the empty hive, take the other from off the stool, and set this last over the bees, who will soon ascend into it, mix with those already there, and become one and the same family. Others, instead of striking the bees down upon the cloth, place with its bottom upmost the hive in which the united swarms are to live, and strike the bees of the other hive down into it. The former of these hives is then restored to its natural situation, and the bees of both hives soon unite. If some bees still adhere to the other hive, they may be brushed off on the cloth, and they will soon join their brethren. Or we may take the following method, which gives less disturbance to the bees. Set with its mouth upmost the hive into which the young swarm has been put, and set upon it the other hive. The bees in the lower hive, finding themselves in an inverted situation, will soon ascend into the upper. A large swarm may weigh 8lb. and so gradually less to 1lb: consequently a very good one may weigh 5 or 6lb. All such as weigh less than 4lb. should be strengthened, by uniting to each of them a less numerous swarm.

Providence has ordained that insects which feed on leaves, flowers, and green succulent plants, are in an insensible or torpid state, from the time that the winter's cold has deprived them of the means of subsistence: thus the bees during the winter are in so lethargic a state, that little food supports them; but as the weather is very changeable, and every warm or sunny day revives them, and prompts them to return to exercise, food becomes necessary on these occasions. Many hives of bees which are thought to die of cold in winter, in truth die of famine, when a rainy summer has hindered the bees from laying in a sufficient store of provisions. The hives should therefore be carefully examined in autumn, and should then weigh at least 18 pounds. The common practice is, to feed them in autumn, giving them as much honey as will bring the whole weight of the hive to near 20 pounds. The easiest and most rational method is, to set under the hive a plate of liquid honey, with a paper pierced full of holes, through which the bees will suck the honey without daubing themselves. In case honey cannot be procured, a mixture of brown sugar, wetted with strong beer, will answer every purpose. Another circumstance which may render it very necessary to feed the bees is, when several days of bad weather ensue immediately after they have swarmed; for then, being destitute of every supply beyond what they carried with them, they may be in great danger of starving. In this case, honey should be given them in proportion to the duration of the bad weather.

In this country it is usual, in seizing the stores of these little animals, to rob them also of their lives. The common method is, that when those which are doomed for slaughter have been marked out, which is generally done in September, a hole is dug near the hive; and a stick, at the end of which is a rag that has been dipped in melted brimstone, being stuck in that hole, the rag is set on fire, the hive is immediately set over it, and the earth is instantly thrown up all around, so that none of the smoke can escape. In a quarter of an hour, all the bees are seemingly dead; and they are rendered soon after irrecoverably so, by being buried in the earth that is returned back into the hole. By this last means it is that they are absolutely killed; for it has been found by experiment, that all the bees, which have been affected only by the fume of the brimstone, recover again, excepting such as have been singed or hurt by the flame. Hence it is evident, that the fume of brimstone might be used for intoxicating the bees, with some few precautions. The heaviest and the lightest hives are alike treated in this manner; the former, because they yield the most profit, with an immediate return; and the latter, because they would not be able to survive the winter. Those hives which weigh from 15 to 20 pounds are thought to be the fittest for keeping.

Mr. Wheler, in his Journey into Greece, p. 411. tells us, that at Mount Hymethus they have a method of saving the bees, which is as follows: The hives they keep the bees in are made of willows or osiers, fashioned like our common dust baskets, wide at top and narrow at the bottom, and plastered over with clay. They are set with the wide end uppermost. The tops are covered with broad flat sticks, which are also plastered over with clay; and, to secure them from the weather, they cover them with a tuft of straw, as we do. Along each side of these sticks, the bees fasten their combs: so that a comb may be taken out whole, without the least bruising, and with the greatest ease imaginable. To increase them in spring time, that is, in March or April, until the beginning of May, they divide them; first separating the sticks on which the

combs and bees are fastened, from one another, with a knife; so, taking out the first comb and bees together on each side, they put them into another basket, in the same order as they were taken out, until they have equally divided them. After this, when they are both again accommodated with sticks and plaster, they set the new basket in the place of the old one, and the old one in some new place. All this they do in the middle of the day, at such time as the greatest part of the bees are abroad; who, at their coming home, without much difficulty, by this means divide themselves equally. This device hinders them from swarming and flying away. In August, they take out their honey; which they do in the day time also, while they are abroad; the bees being thereby, say they, disturbed least: at which time they take out the combs laden with honey, as before; that is, beginning at each outside, and so taking away, until they have left only such a quantity of combs, in the middle, as they judge will be sufficient to maintain the bees in winter; sweeping those bees that are on the combs into the basket again, and then covering it with new sticks and plaster. Various methods have also been adopted in England, to attain the desirable end of getting the honey and wax without destroying the bees; the most approved of which is Mr. Thorley's, who in his Inquiry into the Nature, Order and Government of Bees, thinks colonies preferable to hives. He tells us, that he has in some summers taken two boxes filled with honey from one colony; and yet sufficient store has been left for their maintenance during the winter, each box weighing forty pounds. His boxes are made of deal, and an octagon, being nearer to a sphere, is better than a square form; for as the bees, in winter, lie in a round body near the centre of the hive, a due heat is then conveyed to all the out parts. The dimensions which Mr. Thorley, after many years experience, recommends for the boxes, are ten inches in depth, and twelve or fourteen inches in breadth in the inside. The best and purest honey is that which is gathered in the first five or six weeks: and in boxes of less dimensions we may take within a month, provided the season be favourable, a box full of the finest honey. The top of the box should be made of an entire board, a full inch thick after it has been planed; and it should project on all sides, at least an inch beyond the dimensions of the box. In the middle of this top there must be a hole five inches square, for a communication between the boxes; this hole should be covered with a sliding shutter, of deal or elm, running easily in a groove over the back window. The eight pannels, nine inches deep, and three quarters of an inch thick when planed, are to be let into the top so far as to keep them in their proper places; to be secured at the corners with plates of brass, and to be cramped with wires at the bottom to keep them firm; for the heat in summer will try their strength. There should be a glass window behind fixed in a frame, with a thin deal cover, two small brass hinges, and a button to fasten it. This window will be sufficient for inspecting the progress of the bees. Two brass handles, one on each side, are necessary to lift up the box; these should be fixed in with two thin plates of iron, near three inches long, so as to turn up and down, and put three inches below the top board, which is nailed close down with sprigs to the other parts of the box. Those who choose a frame within, to which the bees may fasten their combs, need only use a couple of deal sticks of an inch square, placed across the box. One thing more, which perfects the work, is, a passage four or five inches long, and less than half an inch deep, for the bees to go in and out at the bottom of the box. In keeping bees in colonies, a house is necessary, or at least a shade; without which the weather, especially the heat of the sun, would soon rend the boxes to pieces. The house may be made of any boards, but deal is the best; and it must be painted, to secure it from the weather. The length of it for six colonies, should be full twelve and a half feet, and each colony should stand a foot distant from the other. It should be three and a half feet high, to admit four boxes one upon another; but if only three boxes are employed, two feet eight inches will be sufficient. Its breadth in the inside should be two feet.

The best time to plant the colonies is, either in spring with new stocks full of bees, or in summer with swarms. If swarms are used, procure if possible two of the same day: hive them either in two boxes, or in a hive and a box: at night, place them in the bee house, one over the other; and with a knife and a little lime and hair, stop close the mouth of the hive or upper box, so that not a bee may be able to go in and out but at the front door. Within a week or ten days the combs will appear in the boxes; but if it be an hive, nothing can be seen till the bees have wrought down into the box. Never plant a colony with a single swarm. When the second box, or the box under the hive, appears full of bees and combs, it is time to raise the colony. This should be done in the dusk of the evening, and in the following manner. Place the empty box, with the sliding shutter drawn back, behind the house near the colony that is to be raised, and at nearly the height of the floor: then lifting up the colony as quickly as possible, let the empty box be put in the place where it is to stand, and the colony upon it; and shut up the mouth of the then upper box with lime and hair, as directed before. When upon looking through the windows in the back of the boxes, the middle box appears full of combs, and a quantity of honey sealed up in it, the lowest box half full of combs, and few bees in the uppermost box, proceed thus. About five o'clock P.M. drive close with a mallet the sliding shutter under the hive or box that is to be taken from the colony. If the combs are new, the shutter may be forced home without a mallet; but be sure it is close, that no bees may ascend into the hive or box to be removed. After this shut close the doors of the house, and leave the bees thus cut off from the rest of their companions, for half an hour or more. In this space, having lost their queen, they will fill themselves with honey, and be impatient to be set at liberty. If, in this interval, upon examining the box or boxes beneath, all appears to be quiet in them, it is a sign that the queen is there and in safety. Hereupon raise the back part of the hive or box so far, by a piece of wood slipped under it, as to give the prisoners room to come out, and they will return to their fellows: then lifting the box from off the colony, and turning its bottom upmost, cover it with a cloth all night; and the next morning when this cloth is removed, the bees that have remained in it will return to the colony. Thus a box of honey is procured, and all the bees are preserved. If the bees do not all come out in this manner, Dr. Warder's method may be followed, es-

pecially if it be with a hive: *viz.* to place the hive with the small end downward in a pail, peck, or flower pot, so as to make it stand firm; then to take an empty hive, and set it upon the former, and to draw a cloth tight round the joining of the two hives, so that none of the bees may get out: after this, to strike the full hive so smartly as to disturb the bees that are in it, but with such pauses between the strokes as to allow them time to ascend into the empty hive; which must be held fast while this is doing, lest it fall off by the shaking of the other. When by the noise of the bees in the upper hive, it is perceived that they are got into this last, carry it to a cloth spread for this purpose before the colony, with one end fastened to the landing place, and knock them out upon it: they will soon crawl up the cloth, and join their fellows, who will gladly receive them.

Mr. Thorley's method of preserving bees in common hives, is incorporation, or uniting two stocks into one, by the help of a peculiar fume or opiate, which will put them entirely in the bee master's power for a time to divide and dispose of at pleasure. But as that dominion over them will be of short duration, he must be expeditious in this business. The queen is immediately to be searched for, and killed. Hives which have swarmed twice, and are consequently reduced in their numbers, are the fittest to be joined together, as this will greatly strengthen and improve them. If a hive is both rich in honey and full of bees, it is but dividing the bees into two parts, and putting them into two boxes instead of one. Examine whether the stock, to which the bees of another are to be joined, has honey enough to maintain the bees of both: it should weigh full 20 pounds. The narcotic, or stupifying fume, is made with the fungus maximus or pulverulentus, the large mushroom, commonly known by the name of bunt, puck fist, or frog cheese. It is as big as a man's head, or bigger when ripe; it is of a brown colour, turns to powder, and is exceedingly light. Put one of these pucks into a large paper, press it to two thirds or near half the bulk of its former size, and tie it up very close; then put it into an oven sometime after the household bread has been drawn, and let it remain there all night: when it is dry enough to hold fire, it is fit for use. The manner of using it is this: cut off a piece of the puck, as large as a hen's egg, and fix it in the end of a small stick slit for that purpose, and sharpened at the other end; which place so that the puck may stand near the middle of an empty hive. This hive must be set with the mouth upward, in a pail or bucket which should hold it steady, near the stock intended to be taken. This done, set fire to the puck, and immediately place the stock of bees over it, tying a cloth round the hives, that no smoke may come forth. In a minute or little more, the bees will be heard falling like drops of hail into the empty hive. Then beat the top of the full hive gently, to get out as many of them as possible: after this, loosing the cloth, lift the hive off to a table, knock it several times against the table, several more bees will tumble out, and perhaps the queen among them. She often is one of the last that falls. If she is not there, search for her among the main body in the empty hive, spreading them for this purpose on a table. Proceed in the same manner with the other hive, with the bees of which these are to be united. One of the queens being secured, put the bees of both hives together, mingle them thoroughly, and drop them among the combs of the hive which they are intended to inhabit. Then cover it with a coarse cloth which will admit air, and let them remain shut up all that night and the next day. It will easily be known when they are awaked from this sleep. The second night after their union, in the dusk of the evening, gently remove the cloth from off the mouth of the hive, and the bees will immediately sally forth with a great noise; but being too late, they will soon return: then inserting two pieces of tobacco pipes to let in air, keep them confined for three or four days, after which the door may be left open. The best time for uniting bees is, after their young brood are all out, and before they begin to lodge in the empty cells. As to the hour of the day, Mr. Thorley advises young practitioners to do it early in the afternoon, in order that having the longer light, they may the more easily find out the queen. He never knew such combined stocks conquered by robbers. They will either swarm in the next summer, or yield an hive full of honey.

Boxes placed laterally will answer every purpose of these of Mr. Thorley, and they may be made square and in the simplest manner.

Bees have various enemies; mice should be guarded against, by diminishing the entrance into the hives when the cold comes on, and the bees are less able to defend themselves; and the hives may be placed in such a manner, that it will be impossible for the mice to reach them. Spiders and caterpillars are very destructive to bees; a species of the latter, called the wax worm, or wax moth, because it feeds on wax, lays its eggs in the hive, which turn to maggots that are very noisome and prejudicial. Hives of bees that have swarmed more than once, and such as contain little honey, are most exposed to these insects; for the empty combs serve them for shelter, and the wax supplies them with food. These hives should be cleaned at least once a week; and the stools on which they rest, where the moths are laid by the bees, should be cleaned every morning. But they cannot be entirely destroyed, without taking away the infected hive, removing the bees, and cleansing it of the moths, before it is restored to its former occupiers. Bees are often troubled with lice, which may be destroyed by strewing tobacco over them. The depredations of birds, and particularly of the house lark and swallow, should be carefully prevented. Ants, woodlice, and earwigs, are also enumerated among the enemies of the bees. Mr. Keys says, "the earwigs steal into the hives at night, and drag out bee after bee, sucking out their vitals, and leaving nothing but their skins or scalps like so many trophies of their butchery." Wasps and hornets are, however, the most formidable enemies that bees have to encounter.

Wasps are very destructive to bees, on account of their superior strength and prodigious numbers, especially in a year favourable to their breeding. They are most numerous in July and August. Soon after that the workers die; but the mothers survive the winter, and commence breeding about April. If cold and wet weather ensues, the greater part of the brood are starved: because the workers cannot fly out for forage, and wasps never lay up any store. Wet is very injurious to their nests, and therefore, in a long season of heavy rain, few wasps will appear till September; but a mild winter, succeeded by a hot spring,

will so favour the increase of wasps, that without the greatest vigilance many stocks will fall victims to their power.

One wasp is a match for three bees. They are very bold, and frequently encounter the most evident danger, undauntedly opposing a host of bees, to obtain a belly full of honey. Therefore, when cold weather commences, knowing that the bees keep no guard then, great numbers get quietly in, and carry off abundance of honey; and having once tasted of the sweets, they will not desist till they possess the whole. Perhaps the same method of destroying them, in this case, as directed for bee robbers, would prove as effectual against wasps.

In the spring the mother wasps may be seen about old timber, with the splints of which they compose their nests. On the blossoms of gooseberries and raspberries they will be found often, and may easily be knocked down and destroyed. Their death, at that time, will prevent a like number of nests from existing the next summer. A nest of wasps is said to consist of 30,000. Effectually to destroy a nest; in the evening, when the wasps have done labour, repair to the place, and stop all the holes of their egress or regress. Introduce a squib into the chief passage, and instantly stopping it with a sod, &c. they will presently be suffocated. Dig the nest up, and burn it. Perhaps a wildfire of damp gunpowder placed on a piece of wood, and introduced, would answer the same purpose.

Hornets, in the spring, will watch the bees as they issue from the hives. When they are seen about the hives, they should be knocked down and trodden upon. They may be trepanned, by placing an empty hive, with its inside smeared with honey, among the stocks. Allured by this, the mother hornets will begin to build in it. In the evening lift up the hive, which may be done with safety, if the mother is there; then set it down again, and in about half an hour after have a vessel with water ready; take the hive and plunge it a little way into the water; then strike smartly on the top of the hive, and the hornets will fall into the water, and by a pair of tongs may be crushed to death. Or, the hive may be closely stopped up till morning; and then taking it into a room, raise the edge next the window; the hornet will fly directly to it, and may readily be destroyed. Their nests are usually hung on the rafters, beams, or roofs of barns, or out houses, or fixed in hollow trees. They resemble a globe of brownish paper.

The nest may be taken by preparing a large mouthed bag, with a running string to draw the mouth close. On a rainy day, or in an evening, put on the bee dress, and with great stillness approach the nest, and draw the bag gently over it, instantly pulling the mouth so close that not a hornet may escape.

APIS, or MUSCA, in astronomy, a southern constellation, containing four stars.

APIUM, PARSLEY, in botany, a genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The fruit is of an oval shape, and streaked; the involucrum consists of one leaf; and the petals are inflected. There are only two species, the culture of which is well known, *viz.*

1. Apium graveolens, or smallage, or celery, a native of England; and,

2. Apium petroselinum, or common parsley, a native of Sardinia.

Smallage, when improved by culture, is termed celery, and there is scarcely a more desirable root, especially as it is a winter sallad. It is aperient and tonic.

With respect to the 2d sort, the roots and seeds of the petroselinum are used in medicine. The root of parsley is one of the five aperient roots; if liberally used, it is apt to occasion flatulencies; and thus, by distending the viscera, produces a contrary effect to that intended by it: the taste of this root is somewhat sweetish, with a light degree of warmth and aromatic flavour. The seeds are an ingredient in the electuary of bayberries, are moderately aromatic, and were formerly used as carminatives. The common parsley is also reckoned an effectual cure for the rot in sheep, provided they are fed with it twice a week for two or three hours each time; but hares and rabbits are so fond of this herb, that they will come from a great distance to feed upon it; so that whoever has a mind to have plenty of hares in their fields, may draw them from all parts of the country by the cultivation of parsley.

APLANATIC, a term applied to that kind of refraction which entirely corrects the aberration of the rays of light, and the colour depending on it, in contradistinction to the word achromatic, in which there is only a partial correction of colour.

APLUDA, a genus of the monoecia order, belonging to the polygamia class of plants: and in the natural method ranking under the fourth order, gramina. The calix is a bivalved gluma: the floscules of the female are sessile, and the male floscules are furnished with pedunculi; the female has no calix; the corolla has a double valve; there is but one stylus, and one covered seed. The male has three stamina. There are 4 species.

APOCYNUM, Κυνος, a dog, because the ancients believed this plant would kill dogs, DOGSBANE: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order contortæ. The essential characters are: the corolla is bell shaped: and the filaments are five, alternate with the stamina. Of this genus botanical writers enumerate 17 species; of which the following are the most remarkable:

1. Apocynum cordatum and villosum, natives of New Spain, and both climbers.

2. Apocynum speciosissimum, a native of Jamaica and of Savannah, whence it has the name of Savannah flower. It rises three or four feet high: the flowers are produced from the sides of the branches, and are very large, and of a bright yellow colour.

3. Apocynum ventum; there are two varieties of this; one with a purple, and the other with a white flower. This species is hardy enough to live in England.

All the species of this plant abound with a milky juice, which flows out from any part of their stalks and leaves when they are broken; this is generally supposed to be hurtful if taken inwardly, but does not blister the skin when applied to it as the juice of spurge and other acrid plants do. The pods of all the sorts are filled with seeds, which have each a long plume of a cottony down fastened to their crowns. This down is in great esteem in France, for stuffing of easy chairs, making quilts, &c. for it is exceedingly light and elastic.

APOCOPE, among grammarians, a figure which cuts off a letter or syllable from the end of a word, as ingeni for ingenii.

APOCRISIARIUS, in antiquity, an officer who delivered the messages of the emperor. He became afterward chancellor, and kept the seals. It was also a title given to a bishop's resident at court, to the pope's deputy at Constantinople, and to the treasurer of a monastery.

APOGEE, that point of the orbit of a planet, or the sun, which is furthest from the earth.

APOLLINARIAN GAMES, in Roman antiquity, an appellation given to certain theatrical entertainments, celebrated annually in honour of Apollo.

APOLLINARIANS, or APOLLINARISTS, in church history, a sect of heretics who maintained, that Jesus Christ had neither a rational human soul, nor a true body.

APOLLONIA, in antiquity, an annual festival celebrated by the Ægialians in honour of Apollo.

APOLLO BELVIDERE, a very celebrated antique statue, esteemed by artists the most excellent and sublime of all the ancient productions. It was found in the 15th century, about 12 leagues from Rome, in the ruins of ancient Antium, and purchased by pope Julius II. who removed it to the Belvidere of the Vatican, whence it takes its name, and where it remained three hundred years, but it is now in the museum at Paris. See SCULPTURE.

APOLOGUE, in matters of literature, an ingenious method of conveying instruction by means of a feigned relation, called a moral fable.

The only difference between a parable and an apologue is, that the former being drawn from what passes among mankind, requires probability in the narration: whereas the apologue being taken from the supposed actions of brutes, or even of things inanimate, is not tied down to the strict rules of probability. Æsop's fables are a model of this kind of writing.

APONEUROSIS, among physicians, a term sometimes used to denote the expansion of a nerve or tendon in the manner of a membrane; sometimes for the cutting off a nerve; and, finally, for the tendon itself.

APOPHYSIS, in anatomy, an excrescence from the body of a bone, of which it is a true continuous part, as a branch is of a tree. See ANATOMY.

APOPLEXY, a distemper in which the patient is suddenly deprived of the exercise of all the senses, and of voluntary motion; while a strong pulse remains with a deep respiration, attended with a stertor, and the appearance of a profound sleep. See MEDICINE.

APOSIOPESIS, in rhetoric, the suppressing or omitting to relate a part of the subject: thus the poet omits the circumstance of Dido's killing herself.

> Dixerat, atque illam media inter talia ferro
> Collapsam adspiciunt.

APOSTATE, among the Romanists, signifies a man who, without a legal dispensation, forsakes a religious order of which he had made profession. Hence,

APOSTATA CAPIENDO, in the English law, a writ which formerly lay against a person who, having entered into some order of religion, broke out again, and wandered up and down the country.

APOSTILICI, an early sect of Christians, who pretended to lead their lives in imitation of the apostles. They condemned marriage.

APOSTROPHE, in rhetoric, a figure by which the orator addresses a person either absent or dead as if he was present; or appeals to angels and to men, to rocks, groves, &c. Thus Adam, in Milton's Paradise Lost:

> O woods, O fountains, hillocks, dales, and bowers,
> With other echo, &c.

APOSTROPHE, in grammar, a mark placed over a letter to show that a vowel is cut off, as call'd for called, th' audience, for the audience.

APOTACTITES, in church history, a name given to the apostolici, from the show they made of renouncing the world more than other men.

APOTHECARY, one who practises the art of pharmacy. In London, the apothecaries are one of the city companies, and by an act which was made perpetual in the ninth year of George I. are exempted from serving upon juries, or in ward and parish offices. They are obliged to make up their medicines according to the formulas prescribed in the college dispensatory, and are liable to have their shops visited by the censors of the college, who are empowered to destroy such medicines as they think not good.

APOTHEOSIS, in antiquity, a ceremony by which the ancient Romans complimented their emperors and great men after their death, with a place among the gods. It is described as follows. After the body of the deceased had been burnt with the usual solemnities, an image of wax, exactly resembling him, was placed on an ivory couch, where it lay for seven days, attended by the senate and ladies of the highest quality in mourning; and then the young senators and knights bore the bed of state through the via sacra to the old forum, and thence to the campus Martius, where it was deposited upon an edifice built in form of a pyramid. The bed being thus placed, amidst a quantity of spices and other combustibles, and the knights having made a procession in solemn measure round the pile, the new emperor, with a torch in his hand, set fire to it, whilst an eagle, let fly from the top of the building, and mounting in the air with a firebrand, was supposed to convey the soul of the deceased to heaven, and thenceforward he was ranked among the gods.

APOTOME, in geometry, the difference between two incommensurable lines: such is the difference between 2 and 1, and such is the excess of the diagonal of a square above its side.

APOTOME, in music, the difference between a greater and lesser semitone, expressed by the ratio 128 : 125.

APPARENT, among mathematicians and astronomers, denotes things as they appear to us, in contradistinction from real or true; thus we say, the apparent diameter, distance, magnitude, place, figure, &c. of bodies.

APPARITION, in astronomy, signifies a star or other luminary's becoming visible, which before was hid. It stands opposed to occultation.

APPARITOR, among the Romans, a general term to comprehend all attendants of judges and magistrates appointed to receive and execute their orders. Apparitor, with us, is a messenger, that serves the process of a spiritual court, or a beadle in an university who carries the mace.

APPEAL, in law, the removal of a cause from an inferior to a superior court or judge, when a person thinks himself aggrieved by the sentence of the inferior judge. Appeals lie from all the ordinary courts of justice to the house of lords. In ecclesiastical causes, if an appeal is brought before a bishop, it may be removed to the archbishop; if before an archdeacon to the court of arches, and thence to the archbishops; and from the archbishop's court to the king in chancery.

Appeal, in our old common law, is taken for the accusation of a murderer by a person who had interest in the party killed; of a felon by an accomplice; or for rape or mayhem by the party injured. It was prosecuted either by writ or by bill: by writ, when a writ was purchased out of the chancery by one person against another, commanding him to appeal some third person of felony, and to find pledges for doing it effectually: by bill, when the person himself gave in his accusation in writing, offering to undergo the burden of appealing the person therein named. The extreme nicety of conducting appeals has caused them to be wholly disused, and the proceeding is now always by indictment. 4 Blacks. 313.

APPEARANCE, in law, signifies a defendant's filing common or special bail, on any process issued out of a court of judicature. In actions by original, appearances are entered with the philazer of the county; and by bill, with the prothonotary.

In perspective, appearance is the projection of a figure or body on the perspective plane.

In astronomy it signifies the same as phenomena or phasis; and in physiology, the same as phasmata.

APPELLANTS, in church history, an appellation given to such of the Roman catholic clergy, as appealed from the constitution unigenitus, to a general council.

APPELLATIVE, in grammar, a noun which is applicable to a whole species or kind, as man, horse; in contradistinction to a proper noun.

APPENDANT, in law, any thing that is inheritable, belonging to some more worthy inheritance; as an advowson, common, or court, may be appendant to a manor, land to an office, &c. but land cannot be appendant to land, for both are corporeal inheritances, and one thing corporeal cannot be appendant to another.

APPLICATION, in geometry, is used for applying one quantity to another, whose areas, but not figures, shall be the same; or for transferring a given line into a circle, or other figure, so that its end shall be in the perimeter of the figure.

By application it is proved in Euclid's elements that two triangles having two sides of one equal to two sides in the other, and the included angles equal, are equal in all respects.

Application is used in Arithmetic for division; thus 16 applied to, or divided by 4, gives 4.

Application, of one science to another, signifies the use that is made of the principles of the one for augmenting and perfecting the other. Thus algebra has been applied to geometry, and vice versa, and both are made use of in illustrating and demonstrating the principles of mechanics, astronomy, navigation, &c. See Geometry.

APPOINTEE, in heraldry, the same as aguisee: thus we say, a cross appointee, to signify that which has two angles at the end cut off, so as to terminate in points.

APPORTIONMENT, in law, the division of a rent into parts, in the same manner as the land out of which it issues is divided: for example, if a person leases three acres of land for a certain rent, and afterward grants away one acre thereof to another, the rent shall be apportioned between them.

APPOSAL of sheriffs, the charging them with money received on their accounts in the exchequer.

APPOSITION, in grammar, the placing two or more substantives together, in the same case, without any copulative conjunction between them; as Ardebat Alexim delicias domini.

APPRAISING, the valuing or setting a price on goods. This is usually done by a sworn appraiser, who, if he values the goods too high, is obliged to take them at the price appraised.

APPREHENSION, in logic, denotes the simple attention of the mind to an object presented either to our senses or our imagination, without passing a judgment, or making any inference. The word is also used to express an inadequate and imperfect idea.

APPRENTICE, a young person bound by indenture to some tradesman, in order to be instructed in the mystery or trade. By the laws of England, a master may be indicted for not providing for, or for turning away his apprentice: and upon complaint from a master, that he neglects his duty, an apprentice may be committed to Bridewell, or be bound over to the sessions. By 5 Eliz. no person can exercise any trade in any part of England, without having served a regular apprenticeship of at least seven years. No trades, however, are held to be within the statute but such as were in being at the making of it in the reign of Elizabeth. Apprenticeships are not necessary to carry on a trade in a country village. And following a trade seven years, either as master or servant, without effectual prosecution, is sufficient without an apprenticeship.

A duty of 6d in the pound is granted for every sum of 50*l.* or under, and 12d in the pound for sums not exceeding 50*l.* given with all apprentices, except such as are placed out by church wardens, &c.

APPRISING, in Scots law, the name of an action by which a creditor formerly became invested with the estate of his debtor for payment.

APPROACH, curve of equable, is of such a nature, that a body descending in it by the sole power of gravity, approaches the horizon equally in equal times. See Curve.

APPROACHES, method of, in mathematics, a name given to a mode of resolving certain problems relating to square numbers, by first assigning certain limits to the quantities required, and then approaching nearer and nearer till a coincidence is obtained. The double rule of false position may be considered as a method of approaches.

Approaches, in fortification, the works thrown up by the besiegers, in order to get nearer a fortress, without being exposed to the enemy's cannon: such, in a more particular manner, are the trenches, which should be connected by parallels, or lines of communication.

Approaching, in fowling, a method of getting near the birds by means of a machine, made of hoops and boughs of trees, within which the sportsman conceals himself.

APPROPRIARE COMMUNIAM, in law, is to discommon, or enclose any parcel of land that before was open and common.

APPROPRIATION, the annexing a benefice to the proper and perpetual use of a religious house, bishopric, college, &c. Where the king is patron, he may make appropriations himself; but in other cases, after obtaining his license in chancery, the consent of the ordinary, patron, and incumbent, is requisite. Appropriations cannot be assigned over, but those to whom they are granted may make leases of the profits. There are in England 2345 impropriations.

APPROVEMENT, in law, is the enclosing part of a common by the lord of the manor.

APPROVER, in law, one who before imprisonment, confessing that he has committed a felony, accuses one or more of his accomplices. Approvers, also, signify bailiffs of lords in their franchises, sheriffs, and likewise such persons as have the letting the king's demesnes in small manors.

APPROXIMATION, in arithmetic and algebra, the coming nearer and nearer to a root or other quantity sought, without expecting to be ever able to find it exactly. There are several methods for doing this, to be found in mathematical books, being nothing but infinitely converging series, some approaching quicker, others slower toward the truth.

By such an approximation the value of a quantity may be found, though not to the utmost degree of exactness, yet sufficiently so for practice. Thus $\sqrt{2} = 1.41421356$, &c. = the approximating series $1 + \frac{4}{10} + \frac{1}{100} + \frac{4}{1000} + \frac{2}{10000} +$, &c. or supposing $x = \frac{1}{10}$, equal to the series $1 \times \frac{4}{x} + \frac{1}{x^2} + \frac{4}{x^3} + \frac{2}{x^4} +$, &c. $= x + 4x^{-1} + x^{-2} + 4x^{-3} + 2x^{-4} +$, &c.

The most easy and general method of approximation, is perhaps by the rule of Double Position, or, what is sometimes called, the Method of Trial and error; which method see under its own name. And among all the methods for the roots of pure powers, of which there are many, the best is that which was discovered by Dr. Hutton, and given in the first volume of his Mathematical Tracts, in point of ease, both of execution and for remembering it. The method is this: if N denote any number, out of which is to be extracted the root whose index is denoted by r, and if n be the nearest root first taken; then shall $\frac{r+1.N+r-1.n^r}{r-1.N+r+1.n^r} \times n$ be the required root of N very nearly; or as $r-1$ times the given number added to $r+1$ times the given number added to $r-1$ times the nearest power, so is the assumed root n, to the required root, very nearly. Then this last value of the root, so found, if one still nearer is wanted, is to be used for n in the same theorem, to repeat the operation with it. And so on, repeating the operation as often as necessary. Which theorem includes all the rational formulæ of Halley and De Lagny.

For example, suppose it were required to double the cube, or to find the cube root of the number 2. Here $r = 3$; consequently $r+1 = 4$, and $r-1 = 2$; and therefore the general theorem becomes $\frac{4N+2n^3}{2N+4n^3} \times n$ or $\frac{2N+n^3}{N+2n^3} \times n$ for the cube root of N; or as $N + 2n^3 : 2N + n^3 :: n$: the root sought nearly. Now, in this case, $N = 2$, and therefore the nearest root n is 1, and its cube $n^3 = 1$ also: hence $N + 2n^3 = 2 + 2 = 4$, and $2N + n^3 = 4 + 1 = 5$; therefore, as $4 : 5 :: 1 : \frac{5}{4}$ or $1\frac{1}{4} = 1.25$ the first approximation. Again, taking $r = \frac{5}{4}$, and $r^3 = \frac{125}{64}$; hence $N + 2n^3 = 2 + \frac{250}{64} = \frac{378}{64} = \frac{189}{32}$, and $2N + n^3 = 4 + \frac{125}{64} = \frac{381}{64}$; therefore, as 378 : 381, or as $126 : 127 :: \frac{5}{4} : \frac{635}{504} = 1.259921$, which is the cube root of 2, true in all the figures. And by taking $\frac{635}{504}$ for a new value of n, and repeating the process, more figures may be found.

APPROXIMATION, *of the roots of equation, by.* Sir Isaac Newton's method for approximating roots is this first take a value of the root as near as may be, by trials, either greater or less; then assuming another letter to denote the unknown difference between this and the true value, substitute into the equation the sum or difference of the approximate root and this assumed letter, instead of the unknown letter or root of the equation, which will produce a new equation having only the assumed small difference for its root or unknown letter; and, by any means, find, from this equation, a near value of this small assumed quantity. Assume then another letter for the small difference between this last value and the true one, and substitute the sum or difference of them into the last equation, by which will arise a third equation, involving the second assumed quantity; whose near value is found as before. Proceeding thus as far as we please, all the near values, connected together by their proper signs, will form a series approaching still nearer and nearer to the true value of the root of the first or proposed equation. The approximate values of the several small assumed differences, may be found in different ways: sir I. Newton's method is this; as the quantity sought is small, its higher powers decrease more and more, and therefore neglecting them will not lead to any material error. He therefore neglects all the terms having in them the second and higher powers, leaving only the first power and the absolute known term; from which simple equation he always finds the value of the assumed unknown letter nearly, in a very neat and easy manner.

For example, let it be required to find the root of the equation $x^2 - 5x = 31$, or $x^2 - 5x - 31 = 0$: Here the root x, it is evident, is nearly $= 8$; for x therefore take $8 + z$, and substitute $8 + z$ for x in the given equation, and the terms will be thus:

$$\begin{array}{rl} x^2 = & 64 + 16z + z^2 \\ -5x = & -40 - 5z \\ -31 = & -31 \end{array}$$

the sum is $-7 + 11z + z^2 = 0$.

Then, rejecting z^2, it is $11z - 7 = 0$, and $z = \frac{7}{11} = .6363$, &c. or $= 6$ nearly.

Assume now $z = .6 + y$: then

$$\begin{array}{rl} z^2 = & .36 + 1.2y + y^2 \\ 11z = & 6.6 + 11y \\ -7 = & -7 \end{array}$$

the sum $-.04 + 12.2y + y^2 = 0$,

where $y = \frac{.04}{12.2} = .003278$ nearly.

Assume it $y = .003278 - v$: then

$$\begin{array}{rl} y^2 = & .000010745284 - .006556v + v^2 \\ 12.2y = & .0399916 - 12.2v \\ -.04 = & -.04 \end{array}$$

the sum $.000002345284 - 12.206556v + v^2 = 0$,

where $v = \frac{.000002345284}{12.206556} = .000000192133$.

Hence, then, collecting all the assumed differences, with their signs, it is found that $x = 8 + z + y - v = 8 + .6 + .003278 - .000000192133 = 8.6003277807867$ the root of the equation required, by Newton's method.

Example 2. Again, taking the cubic equation $y^3 - 2y - 5 = 0$; Newton proceeds thus:

y is nearly $= 2$; take it therefore $y = 2 + p$;

$$\begin{array}{rl} \text{then } y^3 = & 8 + 12p + 6p^2 + p^3 \\ -2y = & -4 - 2p \\ -5 = & -5 \end{array}$$

the sum $-1 + 10p + 6p^2 + p^3 = 0$;

hence $p = \frac{1}{10} = .1$ nearly.

Assume it $p = .1 + q$;

$$\begin{array}{rl} \text{then } p^3 = & 0.001 + 0.03q + 0.3q^2 + q^3 \\ +6p^2 = & 0.06 + 1.2 + 6 \\ +10p = & 1 + 10 \\ -1 = & -1 \end{array}$$

the sum $0.061 + 11.23q + 6.3q^2 + q^3 = 0$;

hence $q = -0.0054$ nearly.

Assume it $q = -0.0054 + r$;

$$\begin{array}{rl} \text{then } q^3 = & -0.000000157464 + 0.00008748r, \text{ &c.} \\ +6.3q^2 = & +0.000183708 - 0.06804r, \text{ &c.} \\ +11.23q = & -0.060642 + 11.23r \\ +0.061 = & +0.061 \end{array}$$

the sum $+0.000541550536 + 11.16204748r$;

hence $r = -0.000048517$. &c.

Hence, $y = 2 + p + q + r$

$= 2 + 0.1 - 0.0054 - 0.000048517$

$= 2.094551483$,

the root of the equation $y^3 - 2y = 5$. And in the same manner sir I. Newton performs the approximation for the roots of literal equations.

APPUI, in the manege, the sense of the action of the bridle in the horseman's hand.

APPULSE, in astronomy, the approach of a planet toward a conjunction with the sun, or any of the fixed stars.

APPURTENANCES, in common law, signify things corporeal and incorporeal that appertain to another thing as principal; as hamlets to a manor, and common of pasture and fishery. Things must agree in nature and quality to be appurtenant, as a turbary, or a seat in a church, to a house.

A PRIORI, a kind of demonstration.

APRON, in gunnery, the piece of lead which covers the touch hole of a cannon.

APSIS, in astronomy, a term used indifferently for either of the two points of a planet's orbit, where it is at the greatest or least distance from the sun or earth. Hence the line connecting these points is called the line of the apsides.

APTENODYTES, in ornithology, a genus of birds that seems to hold the same place in the southern parts of the world as the awks do in the northern. According to Latham, this is the genus penguin. It is seen only in the temperate and frigid zones on that side of the equator which it frequents. The same is observed of the awk in opposite latitudes. See ALCA.

APTERA, in the Linnæan system of zoology, the seventh and last order of insects, the distinguishing characteristic of which is, that the insects comprehended in it have no wings: such are the louse, the flea, the podura, the monoculus, the acarus, the spider, the scorpion, and the crab.

APTOTE, among grammarians, an indeclinable noun, or one which has no variation of cases.

APUS, *avis indica*, a constellation of the southern hemisphere, near the pole, which, according to Bayer's catalogue, contains 12 stars: the largest is of the fifth magnitude.

AQUA, *water*, a term frequently met with in the writings of physicians, chymists, &c. for certain medicines or menstruums, in a liquid form, distinguished from each other by peculiar epithets, as aqua alexiteria, aqua aluminosa, aquafortis, &c. Though formerly thought an element, pure or distilled water is now found to be a compound body of three parts hydrogen and one of oxygen. See AIR, &c.

AQUAFORTIS, nitric acid. See CHYMISTRY.

AQUA MARINA, or AQUA MARINE, a name by which the jewellers call the beryl, on account of its sea green colour.

AQUA REGIA, a combination of nitric and muriatic acids. In the new nomenclature it is called nitro muriatic acid; it is called aqua regia, as the only acid formerly known to dissolve gold.

AQUA *secunda*, aquafortis diluted with water, and employed in the arts.

AQUA *vitæ*, answers to the *eau de vie* of the French, *usquebaugh* of the Irish, whisky of the Scotch, and is a name familiarly applied to native distilled spirits.

AQUEDUCT, in hydraulics and architecture, a conveyance made for carrying water from one place to another. Those of the ancient Romans were surprisingly magnificent. That which Louis XIV. built near Maintenon, for carrying the Bucq to Versailles, is perhaps the greatest now in the world: it is seven thousand fathoms long, with two thousand five hundred and sixty fathoms of

elevation, and contains two hundred and forty-two arcades.

AQUARIANS, in church history, an ancient sect of Christians, who, under pretence of abstinence, made use of water instead of wine in the eucharist.

AQUARIUS, in astronomy, a constellation, which makes the eleventh sign in the zodiac, marked thus, ♒. It consists of forty-five stars in Ptolemy's catalogue, of forty in Tycho's, and in the Britannic catalogue of 108.

AQUARTIA, in botany, a genus of the class and order, tetandria monogynia. The essential character is, calyx bell shaped, corolla wheel shaped, with linear divisions, berry many seeded. There is one species, a native of South America.

AQUATINTA, a method of engraving which very much resembles drawing in Indian ink. This process consists in corroding the copper with aquafortis, in such a manner, that an impression from it has the appearance of a tint laid on the paper. This is effected by covering the copper with a substance, which takes a granulated form, so as to prevent the aquafortis from acting where the particles adhere, and by this means cause it to corrode the copper partially, and in interstices only. When these particles are extremely minute, and near to each other, the impression from the plate appears to the naked eye like a wash of Indian ink. But when they are larger, the granulation is more distinct; and as this may be varied at pleasure, it is capable of being adapted to a variety of purposes and subjects.

The matter generally used for this purpose, is composed of equal parts of asphaltum and transparent resin, reduced to powder and sifted on the plate, which has been previously greased, through a fine sieve. The plate is then heated so as to make the powder adhere, and the artist scrapes it away when a very strong shade is wanted, and covers those parts with varnish where he wishes a very strong light to appear. The aquafortis properly diluted with water, is then put on within a fence of wax, as in common etching for engraving, and by repeated applications, covering the light parts still with varnish, the effect is produced.

AQUEOUS humour, in anatomy, called also the albugineous matter, is the front of the three humours of the eye, and fills up the space between the cornea and crystaline.

AQUILA, in astronomy, a constellation of the northern hemisphere, consisting of fifteen stars in Ptolemy's catalogue, of seventeen in Tycho's, and of seventy-one in the Britannic catalogue.

AQUILARIA, a genus of the class and order decandria monogynia. The essential character is, calyx five cleft; corolla, none; nectarium pitcher shaped, half five cleft with bifid clefts; capsula superior, woody, two celled, two valved; seeds solitary.

There is only one species, a large tree, a native of the mountains of Malacca and Cochin China. The lignum aloes, or aloes wood, is a resinous matter produced by a disease in this tree, which finally kills it. The lignum aloes is highly esteemed in the east as a perfume, and from the bark of this tree is made the common paper, which the Cochin Chinese use for writing.

AQUILEGIA, Columbine, in botany, a genus of the pentagynia order, belonging to the polyandria class of plants; and, in the natural method, ranking under the sixteenth order, multisiliquæ. It has no calyx; the petals are five, with a horn like nectarium inserted between each; and there are five separate capsules. There are five species:

1. Aquilegia Alpina, grows naturally in Yorkshire. The flowers are much larger than those of the garden columbine.

2. Aquilegia Canadensis, or Canada columbine, flowers almost a month before the other sorts.

3. Aquilegia Inversa, or garden columbine. Of this there are great varieties; the colours are chesnut, blue, red, and white, and some are finely variegated.

4. Aquilegia Vulgaris, or wild columbine, with blue flowers, is found growing wild in some woods of England.

5. Aquilegia, viridiflora.

AQUILICIUM, or Aquiliciana, in Roman antiquity, sacrifices performed in times of excessive drought, to obtain rain of the gods.

ARA, in astronomy, a southern constellation, containing eight stars.

ARABESQUE, or Moresque, denotes a style of painting, or of sculpture, so called from the Arabians and Moors, who employed certain ornaments for want of human and animal representations, which their religion prohibited them from using.

ARABIC characters or figures, are the numerical characters made use of in all our arithmetical computations.

Arabic, gum, the name of a gum which distills from a species of mimosa. It is very common among us, but little is to be met with genuine; that is accounted the best which is in smaller pieces, and almost of a white colour. It is useful in all kinds of fluxes, particularly catarrhs.

ARABICI, a sect of Christians, who held that the soul both dies and rises again with the body.

ARABIS, bastard tower mustard: a genus of the siliquose order, belonging to the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquose. The generic mark consists in 4 nectiferous glands which lie on the inside of each leaf of the calyx. There are 14 species; but none of them remarkable for their beauty or their properties. Only one of these, *viz.*

Arabis thaliana, or the mouse ear, is a native of Britain. It grows naturally on sandy ground, or old walls.

ARACHIS, in botany, a genus of the diadelphia decandria class of plants, the flower of which is papilionaceous, and consists of three petals; and its fruit is an oblong unilocular pod, contracted in the middle. There are 2 species chiefly cultivated in Peru, Brazil, and Carolina, for the seed, which constitutes a considerable article of food for the negroes. This seed is a kind of nut, which is perfected in a most extraordinary manner; for as soon as the flower falls off, the germ thrusts itself into the ground, and there the pod is formed and ripened, whence the popular name ground nuts.

ARACHNOIDES, in zoology, a name given to those *echini marini*, or sea hedgehogs, which are of a circular form, but variously indented at the edges.

Arachnoides, is also a species of Madrepora, found fossile. The stars are very small, crowded, and flattened; rays undulated, short and equal.

ARACHNOIDES, in anatomy, an appellation given to several different membranes, in the tunic of the crystalline humour of the eye, the external lamina of the pia mater, and one of the coverings of the spinal marrow.

ARÆOMETER, an instrument to measure the gravity of liquors, which is usually made of a thin glass ball, with a taper neck, sealed at the top, there being first as much mercury put into it as will keep it swimming in an erect posture. The neck is divided into parts, which are numbered, that so by the depths of its descent into any liquor, its lightness may be known by these divisions, for that fluid in which it sinks the least, must be heaviest, and that in which it sinks lowest is the lightest. See HYDROMETER.

ARÆOSTYLE, in architecture, a term used by Vitruvius, to signify the greatest interval which can be made between columns, which consists of eight modules or four diameters.

ARAIGNEE, in fortification, signifies the branch, return, or gallery of a mine.

ARALIA, in botany, a genus of plants with rosaceous flowers, and succulent berries, containing each a single oblong, and hard seed. It belongs to the pentandria pentagynia class of Linnæus. The essential character is flowers, in an umbellule, with an involucrum; cal. 5 toothed superior; cor. 5 petalled; berry 5 seeded. There are 9 species, most of them shrubs and natives of China and America; some are hardy enough to stand our climate in sheltered situations.

ARAMPO, or *Man eater*, a name given by the negroes on the coast of Africa, to a long slender animal, in shape resembling a weasel, with a long tail, and large brush at its extremity. It takes its name from digging up graves and devouring human flesh.

ARANEA concha, the spider shell, a name given to several kinds of murex.

ARANEA, a genus of apterous insects, well known by the common name of spider. The mouth is furnished with short horny jaws; lip rounded at the apex; feelers two, incurved, jointed, very acute at the tip, clubbed with the genitalia in the male; no antennæ; the eyes are eight, or rarely six; feet eight, the anus furnished with papillæ, or teats for spinning. They fix the ends of their threads by applying these nipples to any substance, and the thread lengthens in proportion as the animal recedes from it. They can stop the issuing of the threads by contracting the nipples, and reascend by means of the claws on their feet, much in the same manner as sailors warp up a rope.

The darting out of long threads, which has been observed by naturalists, and by means of which some species of spiders can convey themselves to great distances, deserves particular notice. Dr. Lister tells us, that attending closely to a spider weaving a net, he observed it suddenly to desist in the mid work; and turning its tail to the wind, it darted out a thread with the violence and stream we see water spout out of a jet: this thread, taken up by the wind, was immediately carried to some fathoms long; still issuing out of the belly of the animal. By and by the spider leaped into the air, and the thread mounted her up swiftly. After this discovery, he made the like observation on near thirty different species of spiders; and found the air filled with young and old, sailing on their threads, and doubtless seizing gnats and other insects in their passage, there being often manifest signs of slaughter, legs, and wings of flies, &c. on these threads, as well as in their webs below. The matter of which the spider's threads are formed, is a viscid juice, elaborated in the body of the animal. The young no sooner quit their egg than they begin to spin. Indeed their threads can scarcely be perceived, but the webs may; and no wonder, there being often 400 or 500 little spiders concurring to the same work. There are some kinds of spiders so small at their birth, that they are not visible without a microscope. There are usually found an infinity of these in a cluster, and they only appear like a number of red points: and yet there are webs found under them, though almost imperceptible. What must be the tenuity of one of these threads? Mr. Lewenhock has computed that 100 of the single threads of a full grown spider are not equal to the diameter of the hair of his beard; and consequently, if the threads and hair are both round, ten thousand such threads are not bigger than such a hair.

Garden spiders, Plate X. Nat. Hist. fig. 30. particularly the short legged species, yield silk which has been judged scarcely inferior to that of the silkworm. Mr. Bon of Languedoc, about 70 years ago, contrived to manufacture from it a pair of silk stockings and mittens, of a beautiful natural gray colour, which were almost as handsome and strong as those made with common silk; and he published a dissertation concerning the discovery. But M. Reaumur, being appointed by the Royal Academy to make a further inquiry into this new silk work, raised several objections and difficulties against it. The sum of which amounts to this. The natural fierceness of the spider renders them unfit to be bred and kept together. Four or five thousand being distributed into cells, 50 in some, 100 or 200 in others, the big ones soon kill and eat the less, so that in a short time there were scarcely left one or two in each cell; and to this inclination of mutually eating one another M. Reaumur ascribes the scarcity of spiders considering the vast numbers of eggs they lay. But he affirms, that the silk of the spider is not one fifth of the strength of that of the silkworm. Add to this, that the spider's thread cannot be wound off as that of the silk worm may, but must of necessity be carded; by which means being torn in pieces, its evenness which contributes much to the lustre, is destroyed. Again, spiders furnish much less silk than the worms: the work of 12 spiders only equals that of one silkworm; and a pound of silk will require at least 27,648 spiders.

The species of aranea enumerated by naturalists amount to upward of 50; of which it may here suffice to mention a few of the most remarkable.

1. Aranea aquatica, or the water spider, frequents the fresh waters of Europe. But it is in some sort amphibious: for it can live on land as well as in the water, and comes often on shore for its food; yet it swims well in water, both on its belly and back: it is distinguishable by its brightness. In the water its belly appears covered with a silver varnish, which is only a bubble of air attached to the abdomen by means of oily humours which transpire from its body, and prevent the immediate contact of the water. This bubble of air is made the substance of its dwelling, which it constructs under water: for it fixes several threads of silk, or such fine matter, to the stalks

of plants in the water; and then ascending to the surface, thrusts the hinder part of its body above water, drawing it back again with such rapidity, that it attaches underneath a bubble of air, which it has the art of detaining under water, by placing it underneath the threads, and which it binds like a covering almost all around the air bubble. Then it ascends again for another air bubble; and thus proceeds until it has constructed a large aerial apartment under water, which it enters into or quits at pleasure. It lodges during winter in empty shells, which it dexterously shuts up with a web.

2. Aranea Avicularia, is a native of America, and feeds upon small birds, insects, &c. The bite of this spider is accounted as venomous as that of the serpent.

3. Aranea calycina, lives in the cups of flowers, after the flower leaves have fallen off; and catches bees, and other flies, when they are in search of honey.

4. Aranea Cucurbitina has a globular yellow belly, with a few black spots. It lives in the leaves of trees, and encloses its eggs in a soft net.

5. Aranea Diadema is the largest spider which this country produces. The abdomen is of an oval form, downy, and of a ruddy yellow colour. The upper part is beautifully adorned with black and white circles and dots, having a longitudinal band in the middle, composed of oblong and oval shaped pearl coloured spots, so arranged as to resemble a fillet, similar to those worn by the eastern kings. The legs are of a fine pale green colour; annulated with dark purple or black. It inhabits the birch tree.

6. Aranea Fasciata, with yellow bands round the belly, and dusky rings on the legs, is a native of Barbary, and is as large as the thumb. It inhabits hedges and thickets: its webs have large meshes, and it resides in the centre. Twelve of these spiders, by way of experiment, were shut up together; and, after a battle of eight days, the strongest only remained alive.

7. Aranea Fimbriata, has a black oblong belly, with a white line on each side, and dusky coloured legs. It lives in water, upon the surface of which it runs with great swiftness.

8. Aranea Holosericea, has an oval belly covered with a down, like velvet; at the base, or under part, it has two yellow spots. It is found in the folded leaves of plants.

9. Aranea Labyrinthica, with a dusky oval belly, a whitish indented line, and a forked anus. The web of this species is horizontal, with a cylindrical well or tube in the middle.

10. Aranea Ocellata, has three pair of eyes on its thighs. It is about the same size with the tarantula, of a pale colour, with a black ring round the belly, and two large black spots on the sides of the breast. It is a native of China.

11. Aranea Saccata, lives in the ground, and carries a sack with its eggs, wherever it goes. This sack it glues to its belly, and will rather die than leave it behind.

12. (1) Aranea Tarantula has the breast and belly of an ash colour; the legs are likewise ash coloured, with blackish rings on the under part; two of its eyes are larger than the other, red, and placed in the front; four other eyes are placed in a transverse direction toward the mouth. It is a native of Italy, Cyprus, Barbary, and the East Indies. It lives in bare fields, where the lands are fallow, but not very hard. Its dwelling is about four inches deep, and half an inch wide; at the bottom it is curved, and there the insect sits in wet weather, and cuts its way out if water gains upon it. It weaves a nest at the mouth of the hole. These spiders do not live quite a year. In July they shed their skin. They lay about 730 eggs, which are hatched in the spring; but the parent does not live to see her progeny, as she expires early in the winter. The ichneumon fly is their greatest enemy.

The bite of the tarantula is said to occasion an inflammation in the part, which in a few hours brings on sickness, difficulty of breathing, and universal faintness; the same symptoms return annually, in some cases, for several years; and at last terminate in death. Music, it has been pretended, is the only cure. Such are the circumstances that have been generally related, and long credited, concerning the bite of this animal. But it is now generally agreed, that no such effects attend this bite; and that the exhibitions of dancing to music by persons pretending to be so affected, are only villanous deceptions to excite the compassion and extract the money of the spectators. Plate X. Nat. Hist. fig. 31.

13. Aranea Viatica, or wanderer, is generally of a yellow colour, more or less deep. It is found upon plants; and is a lively, active, indefatigable hunter. Without any motion of the head, which is furnished with immoveable eyes, it perceives all the flies that hover round about, does not scare them, but stretches over them its arms, furnished with feathers, which prove nets in which their wings entangle. It is said to sit on its eggs; which, however, it often carries about with it, wrapped up in a ball of white silk.

ARANEA, in mineralogy, a silver ore found only in the mines of Potosi. It owes its name to the faint resemblance it bears to a cobweb, being composed of threads of pure silver, which to the sight appear like silver lace, when burnt to separate the silk from it.

ARBITER, in civil law, a judge nominated by the magistrate, or chosen voluntarily by two parties, in order to decide their differences according to law.

The civilians make this difference between arbiter and arbitrator: though both ground their power on the compromise of the parties, yet their liberty is different; for an arbiter is to judge according to the usages of the law, but the arbitrator is permitted to use his own discretion, and accommodate the difference in the manner that appears to him most just and equitable.

ARBITRATION, a power given by two or more contending parties, to some person or persons to determine the dispute between them. Matters relating to a freehold, debts due on bond, and criminal offences, are not to be arbitrated. If the party injured by a criminal act, however, proceeds by way of civil action, as in assault or libel, &c. the damages may be submitted to arbitration: also in case of a breach of promise of marriage. The *submission* to arbitration given by the parties must be an agreement or bond upon a stamp, and must not be construed strictly but largely according to the intent of the parties submitted. It commonly contains a clause to protect the arbitrators from any suit in equity that might be brought against them, in consequence of their award; also one to enable them in case they cannot agree, to call in a third arbitrator, by mutual agreement, who is called an umpire. An action of debt may be brought for money adjudged to be paid by arbitrators.

ARBOR, in mechanics, the principal part of a machine which serves to sustain the rest; also the axis or spindle on which a machine turns, as the arbor of a crane, windmill, &c.

ARBORIBONZES, wandering priests of Japan, who subsist on alms. They dwell in caverns, and cover their heads with bonnets made of the bark of trees.

ARBUTUS, the strawberry tree, in botany, a genus of plants with a one leafed bell fashioned flower, and a berry or fruit resembling a large strawberry. See plate.

The strawberry tree belongs to the decandria monogynia class of Linnæus. The essential character is, calyx five parted; corolla, ovate, diaphonous at the base; capsule five celled. There are ten species of this beautiful shrub, all of them tolerably hardy, but they will not bear fruit, except when they are sheltered from the cold winds. The fruit is eatable.

ARC, in geometry, any part of the circumference of a circle, or curved line, lying from one point to another, by which the quantity of the whole circle or line, or some other thing sought after, may be gathered.

ARCH *of a Circle*, the length of an arch may be found by this rule: as 180° is to the number of degrees in the arc, so is 3.1416 times the radius to the length: for when radius is 1 half, the circumference is 3.14159, &c. therefore, $\frac{3.14159}{180}$, &c. = .01745329, &c. = the length of an arch of 1 degree. Hence $r \times .01745$, &c. = the length of 1° to the radius r; and therefore $r \times 0.1745$, &c. × the number of degrees in any arc = the length of that arch.

The length of circular arches may be found in the following manner:

The radius of a circle being 1; and of any arc a, if the tangent be t, the sine s, the co-sine c, and the versed sine v: then the arc a will be truly expressed by several series, as follow, *viz.* the arc

$$a = t - \tfrac{1}{3}t^3 + \tfrac{1}{5}t^5 - \tfrac{1}{7}t^7 \times \tfrac{1}{9}t^9 \text{ &c.}$$

$$a = \frac{s}{6} - \frac{1}{3}\cdot\frac{s}{c^3} + \frac{1}{5}\cdot\frac{s}{e^5} - \frac{1}{7}\cdot\frac{s}{c^7} \text{ &c.}$$

$$a = s + \frac{1}{2.3}s^3 + \frac{1.3}{2.4.5}s^5 + \frac{1.3.5}{2.4.6.7}s^7 \text{ &c.}$$

$$a = \sqrt{2v} \times \left(1 + \frac{1}{2.3}\cdot\frac{v}{2} + \frac{1.3}{2.4.5}\cdot\frac{v^2}{2^2} + \frac{1.3.5}{2.4.6.7}\cdot\frac{v^3}{2^3} \text{ &c.}\right)$$

$a = \frac{3.14159, \text{ &c.}}{180} d = .01745329, \text{ &c.} \times d$; where d denotes the number of degrees in the given arc. Also, $a = \frac{8c - c}{3}$ nearly; where c is the chord of the arc, and c the chord of half the arc; whatever the radius is.

To investigate the length of the arc of any curve. Put x = the absciss, y = the ordinate, of the arc x, of any curve whatever. Put $\dot{z} = \sqrt{\dot{x}^2 + \dot{y}^2}$; then, by means of the equation of the curve, find the value of $\dot{x}$ in terms of $\dot{y}$, or of $\dot{y}$ in terms of $\dot{x}$, and substitute that value instead of it in the above expression $\dot{z} = \sqrt{\dot{x}^2 + \dot{y}^2}$; hence, taking the fluents, they will give the length of the arc z, in terms of x or y. See FLUXIONS.

ARCH *of equilibration*, is that which is in equilibrium in all its parts, having no tendency to break in one part more than in another, and which is therefore safer and stronger than any other figure. Every particular figure of the extrados, or upper side of the wall above an arch, requires a peculiar curve for the under side of the arch itself, to form an arch of equilibration, so that the incumbent pressure on every part may be proportional to the strength or resistance there. When the arch is equally thick throughout, a case that can hardly ever happen, then the catenarian curve is the arch of equilibration; but in no other case; and therefore it is a great mistake in some authors to suppose that this curve is the best figure for arches in all cases; when in reality it is commonly the worst. This subject is fully treated in Dr. Hutton's Principles of Bridges, prob. 5, where the proper intrados is investigated for every extrados, so as to form an arch of equilibration in all cases whatever. It there appears that when the upper side of the wall is a straight horizontal line, as in the figure, Plate XIV. fig. 3. the equation of the curve is thus expressed,

$$y = h \times \frac{\text{log. of } \frac{a + x + \sqrt{2ax + xx}}{a}}{\text{log. of } \frac{a + r + \sqrt{2ar + rr}}{a}}$$

where x = DP, y = PC, r = DQ, h = AQ, and a = DK. And hence, when a, h, r, are any given numbers, a table is formed for the corresponding values of x and y, by which the curve is constructed for any particular occasion. Thus, supposing a or DK = 6, h or AQ = 50, and r or DQ = 40; then the corresponding values of KI and IC, or horizontal and vertical lines, will be as in this table.

Table for constructing the curve of Equilibration.

Value of KI	Value of IC.	Value of KI.	Value of IC.	Value of KI.	Value of IC.
0	6.000	21	10.381	36	21.774
2	6.035	22	10.858	37	22.948
4	6.144	23	11.368	38	24.190
6	6.324	24	11.911	39	25.505
8	6.580	25	12.489	40	26.894
10	6.914	26	13.106	41	28.364
12	7.330	27	13.761	42	29.919
13	7.571	28	14.457	43	31.563
14	7.834	29	15.196	44	33.299
15	8.120	30	15.980	45	35.135
16	8.430	31	16.811	46	37.075
17	8.766	32	17.693	47	39.126
18	9.168	33	18.627	48	41.293
19	9.517	34	19.617	49	43.581
20	9.934	35	20.665	50	46.000

Arcs, similar. If the arc of one curve contains the same number of degrees as the arc of another; or if the radius of one curve is to the radius of another, as the arc of one curve is to its corresponding one, then these two arcs are similar.

Arcs, equal, those which contain the same number of degrees, and whose radii are equal.

Arc, diurnal, that part of a circle described by a heavenly body, between its rising and setting; as the nocturnal arch is that described between its setting and rising; both these together are always equal.

Arc of progression or direction, an arch of the zodiac, which a planet seems to pass over, when its motion is according to the signs.

Arc of retrogradation, an arch of the zodiac, described by a planet, while it is retrograde, or moves contrary to the order of the signs.

ARCA, in conchology, a genus of *bivalves*, the animal of which is supposed to be a tethys: the valves are equal; and the hinge beset with numerous sharp teeth, inserted between each other. The species are divided into two sections; the first has an entire margin, and in the other the margin is crenulated.

ARCADE, in architecture, is used to denote any opening in the wall of a building forming an arch.

ARCH, in architecture, a concave building, with a mould bent in form of a curve, erected to support some structure. See Architecture.

ARCHBUTLER, one of the great officers of the German empire, who presents the cup to the emperor, on solemn occasions. This office belongs to the king of Bohemia.

ARCHCHAMBERLAIN, an officer of the empire, much the same with the great chamberlain in England. The elector of Brandenburgh was appointed, by the golden bull, archchamberlain of the empire.

ARCHCHANCELLOR, an high officer, who, in ancient times, presided over the secretaries of the court. Under the two first races of the kings of France, when their territories were divided into Germany, Italy, and Arles, there were three archchancellors; and hence the three archchancellors still subsisting in Germany, the archbishop of Mentz being archchancellor of Germany, the archbishop of Cologn of Italy, and the archbishop of Treves of Arles.

ARCHDEACON, an ecclesiastical dignitary or officer, next to a bishop, whose jurisdiction extends either over the whole diocese, or only a part of it. There are sixty archdeacons in England.

ARCHDUKE, a title given to dukes of greater authority and power than other dukes.

ARCHED legs, a fault in a horse, when his knees are bent archwise.

ARCHER, in the ancient military art, one who fought with bows and arrows.

The English archers were esteemed the best in Europe, to whose prowess and dexterity the many victories over the French were in a great measure owing.

ARCHERY, the art of shooting with a bow and arrow. This art either as an instrument in war or an object of amusement, may be traced in the history of almost every country. Our own was in its earliest periods highly celebrated for its skill in archery; and it appears that the English monarchs took great pains to encourage the exercise of the long bow. Edward III. ordered a complaint to be lodged against the sheriff of London, for permitting other useless games to be pursued, when the leisure time of his people upon holidays ought to be spent in the recreations of archery. In the reign of Ed. IV. an act was made that every Englishman should have a bow of his own height to be made of yew, hazel, ash, &c. and mounds of earth were ordered to be made in every township, and the inhabitants to practise archery, under certain penalties. During the reigns of Henry VII. and VIII. archery was also encouraged; in the third of Henry VIII. a statute was made commanding every father to provide a bow and two arrows for his son, when he was seven years old. By the founder of Harrow school, shooting with bow and arrow was insisted upon as a fundamental part of the regulations.

ARCHES, or Court of Arches, the supreme court belonging to the archbishop of Canterbury, to which appeals lie from all the inferior courts within his province.

ARCHIL, a moss of a gray colour, which grows on the rocks in many parts of the Archipelago, and on the western coast of England. It yields a purple tincture, fugitive indeed, but very beautiful, which is the best chymical test for acids and alkalies, and is known by the name of tincture of litmus. By the addition of tin it is rendered durable as a dye, and it then approaches to scarlet. Archil is however most commonly used to give a bloom to pinks and other colours. It readily gives out its colouring matter to water or any spirit.

ARCHILOCHIAN, a term in poetry applied to a sort of verses, of which Archilochus was the inventor, consisting of seven feet, the four first whereof are ordinarily dactyls, though sometimes spondees, the three last trochees: as in Horace,

Solvitur acris hyems, gratâ vice veris et Favoni.

ARCHITECT, Αρχιτεκτων, of ἀρχὸς chief, and τεκτων, an artificer or builder, a professor of the art of building. The architect's business and his glory, is the designing of a work, and his genius is displayed, as well in the general symmetry, ornaments, and magnificence of his plan, as in the useful arrangement of its internal distribution.

The necessary qualifications of a great and perfect architect, are numerous and hard of attainment. He should be profoundly skilled in the knowledge of the properties of the materials he employs, the strength and durability of them, the method of connecting them together in the nearest direction to that in which they can be employed with their full strength; and this implies geometrical skill as well as physical knowledge.

He should be skilled in perspective; and it is necessary that he should be a quick and correct, though he may not attain to be a fine, draftsman. Some of the time employed by young architects in practising this art, would be much more usefully spent in acquiring a general knowledge of natural philosophy.

He should have a full knowledge of the various practised modes of combining together the materials of his building; to guide his mathematical reasoning, on the variety of new combinations his own practice may acquire: he should not merely design his roof, and trust to the carpenter for the judicious execution; nor plan the figure of

his stair, and let the mason find out the safe means of sustaining its weight, with regular and proportionate solidity.

In our climate, he should perfectly understand the best means of generating, distributing, and retaining warmth in his building, and plan his apartments with this material object in view. He should be able to direct the unscientific mere manufacturer, of grates and contrivances to contain the necessary fuel for this purpose. He should never build an imperfect chimney to infest his house with smoke in the apartments, and counteract the tendency of the fire, to carry it off into the atmosphere. In warmer regions his skill must be displayed in arranging the facilities for cooling his apartments.

He should have a perfect knowledge of the proportions of the beautiful models of antiquity, and genius to animate and direct him in the application of his acquirements.

Vitruvius, Palladio, Vignola, Inigo Jones, de Lorme, sir Christopher Wren, the earl of Burlington, and sir William Chambers, were very celebrated architects.

ARCHITECTURE, the art of building, or a science which teaches how to erect buildings, either for habitation or defence. The origin of this noble science may be traced in the Indian's hut and the Greenlander's cave; they show the rude beginning from which it has grown to its present perfection and magnificence. It is an art of the first necessity, and almost coeval with the human species. Man, from seeking shade and shelter under the trees of the forest, soon felt the necessity and saw the utility of bending them to more commodious forms than those in which he found them disposed by nature. To huts made of trees and branches leaning together at top, and forming a conical figure plastered with mud, succeeded more convenient, square, roofed habitations. The sides of these habitations, and the inner supports for the crossbeams of the roofs, being trunks of trees; from them were derived those beautiful, symmetrical columns, *the Orders of Architecture.*

Though the art of building was cultivated by the ancient Egyptians, Assyrians, and Persians, with great success in the production of such gigantic structures as the pyramids of Egypt which exist to this day, and the Labyrinth seen by Herodotus, with other works of extraordinary and vast magnificence; yet we owe to the Greeks the first structures, in which elegance and symmetry were combined with comfort and convenience in the plan.

The established five orders of architecture, the Tuscan, the Doric, the Ionic, the Corinthian, and the Composite, were brought to perfection under the Greeks and Romans. Modern efforts have added little or nothing to the beauty and symmetry of these columns, and the parts dependent on them; but much has been done in the internal improvement of mansions and houses.

Roman and Grecian architecture, which teaches the proportions and arrangement of the orders invented by them, being called ancient; modern, or practical architecture, will chiefly relate to the art of distributing the apartments with more attention to domestic economy, convenience, and comfort. And if we have not surpassed the taste of the ancients, in external design and ornament, nor equalled them in the durability and vast extent of their buildings, the ruins of which astonish us at this day; yet doubtless the natural and first purposes of the art are more completely answered, and the people in general are more comfortably lodged.

A practice of raising up houses of a too expensive and heavy solidity, is unfavourable to the general improvement of the art in respect of domestic economy and convenience. Accordingly the facility of procuring stone, and the want of brick earth, has produced in the capital of France, houses of enormous strength, and the buildings last too long; while the slighter ones of London are more easily susceptible of the changes necessarily introduced by improvements in the arts, and inventions for promoting domestic economy and comfort. The speculations of needy or avaricious builders, however, lead us into the opposite extreme but too often, and buildings are erected which very soon after they are finished require essential repairs to keep them up during the terms of the leases.

Besides ancient and modern architecture, a third style of building may be traced from the same source with the former. Amongst the northern nations of Europe originated the style called Gothic; which after the destruction of the Roman empire by these people, they introduced in Europe to the exclusion of the Greek and Roman manner of architecture. Like the ancient Egyptians, they sometimes seem to have been more studious to astonish the eye with great and vast masses of stone, than to please by symmetry of design, or beauty of ornament.

But there are two species of Gothic; the Saxon, heavy, plain, and robust, like the Tuscan; the other, like Corinthian or Composite architecture, light, airy, and ornamental, received its finish from the hand of the Normans, and was by them introduced into this country.

A grove of tall trees, meeting at top with interweaved branches, is the natural and beautiful model from which the aisle of the Norman Gothic cathedral is derived.

A mistaken prejudice has prevented the due study of this style of building, though the most exquisite remains of it adorn our island; in the structures of which, much mathematical and geometrical skill may be observed: and we cannot help observing with bishop Warburton, that "our Gothic ancestors had juster and manlier notions of magnificence on Grecian and Roman ideas, than those enemies of taste, who profess to study only classic elegance."

Sir William Chambers remarks, "that to those usually called Gothic architects we are indebted for the first considerable improvements in construction;" "that there is a lightness in their works, an art and boldness of execution, to which the ancients never arrived, and which the moderns comprehend and imitate with difficulty." But to this manner of building, modern improved distribution is not easily adapted; though it seems peculiarly proper for religious edifices.

OF THE FIVE ORDERS.

The Tuscan Order.

Although there are no ancient remains of it, this order is generally placed first on account of its plainness; and Vitruvius only mentions in an indistinct manner the general proportions of it. The Trajan and Antonine columns at Rome are commonly called of the Tuscan order, though they have eight diameters for their height, and the

torus and capitals do not exhibit Tuscan plainness. It is highly probable the Tuscan is only a simplification of the Doric, of which there are so many very ancient remains; but to Tuscany it evidently owes its name, from being employed there, in several large edifices.

Its proportions are, fourteen modules or seven diameters for the height of the column; three modules and a half for the whole entablature, which being divided into ten equal parts, three are for the height of the architrave, three for the frize, and four for the cornice: the capital is in height one module. The base, including, as is peculiar to the measurement of this order, the lower cincture of the shaft, is one module; and the shaft with its upper cincture and astragal is twelve modules. For interior use the height of the column may be fourteen modules and a half, or fifteen modules, and the increase may be in the column only. It is customary to diminish this order one quarter, but the diminution of one eighth or sixth would better accord with its character of strength.

The Doric Order.

Of the Doric Order, the very ancient remains exhibit proportions so dissimilar to the practice of latter times, that they must have been produced before experience had matured the rules of art. In several parts of the ruins of Athens, these columns are seen of a height not exceeding four diameters, and four and a half. Strength was more regarded than elegance of design in these low proportions. Columns of near six diameters may be found in the temples of Minerva and Theseus, at the same place; and the columns of the more ancient temple of Apollo, at Delos, have five diameters, and are fluted in the neck, and on the foot. There are columns of upward of six diameters in height found in other buildings at Athens; and the temple of Hercules at Cora, has columns of eight diameters and three quarters, and they are on bases, which the others are not.

Vitruvius, allowing it to be the most ancient order, ascribes its origin to Dorus, who built a temple to Juno, in the ancient city of Argos. But afterward, Ion, who built a temple to Apollo in Asia, fixed the proportions of this order; and being guided by the example of nature in the structure of man, gave six times the length of the foot, or diameter of its base, for the height.

The practice of the moderns allows eight diameters, with a base; an addition to the ancient plan of this column, no less useful than elegant. Some of the most ancient columns of this order are fluted, and some squared off, or wrought with pans instead of hollows. The cracks, or divisions, in the bark of the trees originally employed for pillars, very naturally suggested fluting when any ornament was desired.

The place and form of the triglyph, an ornament peculiar to this order, are both evidently derived from the ends of projecting joints, laid from the inner to the outer walls of buildings. When as much of the timber as appeared unhandsome was cut off, tablets like the triglyphs now in use were fastened on the sawed ends, and produced a pleasing effect. The triglyphs, interjoists, and metope, in Doric work, had their origin from the disposition of the timbers in the roof; afterward, in other works, some made the rafters that were perpendicular over the triglyphs to project outward, and carved their projecture; hence as the triglyphs arose from the disposition of the joists, so the mutules under the corona were derived from the projecture of the rafters; wherefore in stone or marble structures, the mutules are represented declining in imitation of the rafters; and also on account of the droppings from the eaves, it is proper they should have such declination. This also explains the situation and form of the guttæ or drops. The ornaments on the metope, or space between the triglyphs, may have been originally trophies of the deity, or implements of sacrifice placed there: the bull's skull is peculiar to the Doric order.

According to the modern proportions of this order, let the height of the column, including its capital and base, be sixteen modules, the height of the entablature four modules, which being divided into eight parts, two are for the architrave, three for the frize, and three for the cornice: the base will be one module in height, the capital thirty-two minutes, or a little more.

The Ionic Order.

To the before mentioned Ion, is ascribed by Vitruvius, the origin of this more delicate or feminine order; of which the volutes of the capital, ornamented with festoons, are like locks of hair decorated with flowers. Succeeding architects much approving the taste and ingenuity of this design, allowed eight diameters and a half to the order. The celebrated Hermogenes, when building the temple of Bacchus at Teos, rejected the Doric after all the marbles were cut, and adopted the Ionic instead. And indeed the difficulties of adjusting the mutules, metope, and triglyphs, with propriety in Doric structures, and the massive appearance of the order, caused a frequent preference of the Ionic. Denteles belong to the Ionic cornice: they represent the assers, or smaller rafters, supporting the tiles.

On the antique Ionics, the volutes are generally placed parallel, and to Michael Angelo is attributed, as a new invention, the executing them on an angular plan, though some ancient examples of this manner may be seen. It has been attempted to prove, that the accidental pleasing forms of convolution in shells, gave the first idea of the Ionic volute.

Eighteen modules are given, as a modern proportion for the height of the column of this order; and for the entablature, four modules, or four and a half, which is less than the antique Ionics. The capital is twenty-one minutes, and the base thirty minutes in height; the shaft may be plain, or fluted with twenty or twenty-four flutings, whose plan should be a trifle more than a semicircle, and the breadth of the fillet between them should not be more than one third of the flute. The ornaments of the capital are to correspond with the flutings of the shaft, and there must be an ove above the middle of each fluting. The entablature being divided into ten equal parts, three are for the architrave, three for the frize, and four for the cornice. In interior work, where delicacy is required, the height of the entablature may be reduced to one fifth of the height of the column.

The Corinthian Order.

The Corinthian order has arisen out of the two former, and has nothing but the capital peculiar to itself; of which the origin, from the leaves of a root of acanthus springing round a basket, and curling in the manner of a volute

against a tile which covered it, which answers to the abacus, is recorded by Vitruvius. This pleasing accidental combination, was copied by Callimachus; who saw it, and was struck with the elegance and novelty of the effect. The other members placed on the Corinthian pillar, are common to the Doric and Ionic orders.

The many examples existing amongst the fragments of antiquity, evince the great prevalence of the Corinthian order, amongst the ancients: but the Romans annihilated every vestige of it in Corinth, where it had its origin, in their barbarous destruction of that rival city.

The moderns have adopted these proportions: the columns are twenty modules in height; the entablature, five modules; the base one module, and may be either attic or Corinthian. The capital has seventy minutes in height; the proportion of the members in the entablature, is the same as in the Tuscan and Ionic orders. If the entablature is enriched, the shaft of the column may be fluted, and the flutings may be filled to one third part of their height with cabling; and in very rich decorations, the cabling may be composed of reeds, husks, ribands, flowers, &c.

The capital is enriched with olive leaves, as are almost all the antiques of this order at Rome; the acanthus being seldom employed, but in the composite. The entablature may be reduced to two ninths or one fifth of the height of the column: in which case it is best to use the Ionic entablature, or reduce the denteles of the cornice.

The Composite Order.

In a successful attempt at pleasing variety and novelty, the Romans produced the composite order, by combining the proportions and enrichments of the Corinthian, with the angular volute of the Ionic.

The omission of the upper row of leaves in the capital, and the addition of the Ionic volute, give it a bolder aspect than the Corinthian: uniting elegance and a very pleasing projection. In the triumphal arches of Rome, erected at the very height of its splendour, it was used with a happy effect, as well as in many other examples in that city.

The height of the column is twenty modules, according to modern proportions; that of the entablature five modules; the capital has seventy minutes in height. The base measures the same as in the Doric and Ionic orders; and as the module is less all its parts will be more delicate. The shaft may be enriched with twenty or twenty-four flutings, and the principal members of the entablature may have the same proportions as in the two former orders.

If we class the orders of architecture according to their destination, we shall limit them to three: the first class, including the Tuscan and Doric, for supporting plain and massy buildings; one for buildings of a more elegant and light form, and one between these two. The Ionic and the Corinthian, with their varieties, will compose the last classes.

The cyma and cavetto are constantly used as finishings by the ancients, and never applied where strength is required. The ovolo and talon are always employed as supporters to the essential members of the composition, such as the modillions, denteles, and corona. The chief use of the torus and of the astragal, is to strengthen the tops and bottoms of columns, and sometimes of pedestals, where they are frequently cut in the form of ropes. The scotia is employed only to separate the members of bases. The fillet is also used for this purpose in all kinds of profiles, as well as in bases.

An assemblage of essential parts and mouldings is called a profile: the best are composed of few mouldings, varied in form and size, fitly applied; the straight and curved ones placed alternately. Every profile should have a predominant member, which the others should seem made to support, fortify, or shelter from the injuries of the weather: as in a cornice, where the corona is principal, the cyma or cavetto cover it, and the modillions, denteles, ovolo, and talon, support it.

When ornaments are employed to adorn the mouldings, all of them must not be carved, that the eye may find a proper repose on the plain ones, or the figure of the profile will be lost. The square members being generally either principal in the composition, or used as boundaries to other parts, should rarely be carved.

When mouldings of the same size and form occur in one profile, they should be enriched with the same kind of ornament. The addition of rusticated cinctures to columns, is an ungraceful modern invention; but rustic work is introduced with great propriety and effect into gates, large entrances, grottos, baths or fountains, and for low basement stories.

To each order belongs a particular base; the Tuscan has only a torus and a plinth: the Doric base has an astragal more than the Tuscan; the torus is larger, on a double scotia, with two astragals between them on the Ionic base. The Corinthian base has two toruses, two scotias, and two astragals; the Composite base has one astragal less than the Corinthian.

Columns are generally diminished one sixth part of their lower diameter, which diminution begins at one third part of their height. Some architects allow a small swell in the lower part of the middle division of the pillar.

But in columns from fifteen to twenty feet high, the lower diameter being divided into six parts and a half, take five parts and a half for the diameter at the top. Columns from twenty to thirty feet high are diminished one seventh. From thirty to forty feet, the lower diameter being divided into seven parts and a half, six and a half may be taken for the upper diameter: and from forty to fifty feet high, they may be diminished one eighth part, and so on in proportion.

Pedestals consist of three principal parts, the base, the dye, and the cornice, and are used only to elevate the columns to a necessary height. No particular proportions can be assigned for them; but it is common to give them from one third to one quarter of the height of the column and entablature, which being divided into nine parts, two are for the base, one for the cornice, and six for the dye of the pedestal, which is of equal dimensions with the plinth of the column. The enrichments are of course regulated by those of the entablature of the particular order which the pedestal may carry. One pedestal only is necessary for two columns placed together, and a continued pedestal with projections in the cornice, under each column, must be used for a colonnade or peristyle; but if other circumstances permit, columns the whole necessary height, without pedestals, should be used, and will always have a more majestic appearance.

Pilasters follow in their parts the orders of columns, and admit of a like diminution, but are square instead of round

in their plan. They are however to be seen, not diminished, in ancient and modern works, and chiefly so, when they occur on outer corners.

Pilasters are employed in internal decorations to save room, and seldom project beyond the solid wall, above one quarter of their diameter; and sometimes they are seen on the external part of buildings, alone and with columns. When placed behind, and very near columns, they need not project above one eighth part of their diameter. Pilasters are adorned like columns, and the profile of their capitals is nearly the same.

Attics. In Athens, where it was for many ages a rule to conceal the roofs of buildings, attics had their origin. A line of low columns and pedestals, or of columns and balusters may be employed for this purpose. They should be less in height than one third of the order on which they are placed, but not lower than one quarter. If the attic is composed of a low order, the base and cornice may have the same mouldings as the pedestals of the columns, and with the dye, bear the same proportion to each other; and when they form pilasters over the columns of the building, the breadth of the bases must not exceed the upper diameter of the columns which they surmount.

Caryatides. Representations of the human figure, the male called Persians, and the female Carians, or Caryatides, have been employed to support the entablatures of buildings. These were invented and used in memory of the captivity of the Persians and Carians by the Athenians. The Persians may be of any size, with a Doric entablature, bearing the same proportion to the figure as to columns of the same height; but the Caryatides or female figures, ought to have Ionic or Corinthian entablatures, and not to be larger than life.

Termini, figures which owe their origin to the stones used by the ancients to distinguish the limits of their possessions, are employed to support the entablatures of monuments, chimney pieces, and such small compositions, and as ornaments in gardens or fields.

Of the temples of the ancients.

Of the many remaining sacred buildings of the ancients, seven orders may be distinguished.

Antis. The first order has antæ or pilasters in front, at the corners of the walls which form the cell, or enclosed space within the walls, and between the pilasters in the middle, two columns which support the pediment or porch.

The prostyle is the same as the antis, only columns are added opposite the pilasters of each corner, which support a chapiter or architrave, as in the antis.

The amphiprostyle has only a postern, or back front added, with columns and pediment, like the prostyle.

The peripteral has in the front and hinder porch six columns, and eleven, including the corner ones on each side; and these columns are placed with the space of an intercolumniation between them and the wall of the building, leaving an ambulatory round the cell of the edifice.

In the pseudo dipteral the columns are so placed, that in front and behind there are eight, and on each side fifteen with the corner columns; and the walls of the cell must correspond with the four centre columns before and behind, leaving the space of two intercolumniations, and the thickness of one column between the walls and the outer column.

The dipteral is octostyle, or eight columned before and behind, but it has a double row of columns round the cell.

The hypethral is decastyle, or ten columned before and behind, having the other parts the same as the dipteral; but it has a double row of columns within, all round, one above another, resembling a porch, which is called a peristyle: the middle has no roof, and it has folding doors before and behind.

Of round temples. Some are monopteral, without cells, and built on columns; others are called peripteral, and have an ascent of two steps, on which the pedestals of the columns are placed. The wall of the cell is distant one fifth part of the diameter of the temple from the pedestals of the columns. The monopteral have a tribunal or throne, and are ascended by steps; and the columns placed on pedestals are as high as the diameter of the temple, taken at the outside of the pedestals.

On the proper disposition of columns depend the elegance and grandeur of a building, for which Vitruvius lays down the rules observed by the ancients, and admitted by the moderns.

The five species of buildings, according to the disposition of the columns, are the pycnostyle, thick of columns; the systyle, with columns wider apart; the diastyle, still wider; the aræostyle, more distant than is proper; and the eustyle, with columns at a proper distance.

In the pycnostyle, the distance of the intercolumniation is one diameter and a half of the column. The systyle has two diameters. The diastyle has three diameters of the column for the intercolumniation, but the architrave, on account of the distance, is liable to break. In the aræostyle the beams are made of durable timber. The eustyle is formed by allowing the distance of two diameters and a quarter for the intercolumniations, except the middle one which must have three diameters.

For the eustyle, the rule is, that the front of a building, if it is tetrastyle, of four columns, is divided into eleven parts and a half, without reckoning the projection of the base of the column. If hexastyle, of six columns, into eighteen parts. If octostyle, of eight columns, into twenty-four parts and a half. Of these parts each shall be equal to the diameter of a column. Each intercolumniation must be two and a quarter of these parts; but three must be allowed for the middle one; and for the height, eight diameters and a half. The columns to the aræostyle should have for their thickness one eighth part of their height. For the diastyle, the height of the column is to be divided into eight parts and a half, and one part taken for the thickness of the column. For the systostyle, the height must be divided into nine parts and a half; one part being the thickness of the column. In the pycnostyle, the height shall be divided into ten parts, each equal to the diameter of the column. The eustyle is also divided into eight parts and a half, like the diastyle. As the space between the columns increases, so ought the thickness of the columns. If it is aræostyle, and they should have only a ninth or tenth part for their thickness, they will appear tall and slender, on account of the breadth of the intervals. If it is pycnostyle, and the columns

have an eighth part for their thickness, they will, on the contrary, have a heavy and ungraceful appearance. The thickness of corner columns must be increased one fiftieth part, for the great surrounding space will diminish their effect on the eye, and make them appear smaller than they really are.

It must not, however, be omitted that the ancients did not always rigidly adhere to these rules of Vitruvius for the disposition of columns, which therefore should not fetter the genius, nor hinder the researches, of moderns.

Of the private buildings of the ancients, Vitruvius says, describing the houses of persons of distinction, the Greeks used no atrium or hall, but from the gate of entrance made a passage of no great breadth, on one side of which was the stable, and on the other the porter's rooms; and these were terminated by the inner gate. Passing on, was the peristylium, having porticos on three sides. On the south side were two antæ, which support and form a passage, within which, to the right and left, were the great œci, in which the mistress of the family and the work women resided. To the right and left were cubiculi or chambers, of which one was called thalamus, the other amphithalamus; and under the porticos of the peristyle, were the common dining rooms, chambers, or family rooms. This part of the edifice was called gnyæconitis.

Through the passage, with the antæ, was a larger house, with a more spacious peristyle, in which were four porticos of equal height: or sometimes the one which looked toward the south had higher columns, and this peristyle which had one portico higher than the rest was called Rhodian. These houses had elegant vestibules, magnificent gates, and the porticos of the peristyle were ornamented with stucco plaster, and lacunariæ compartments. In the portico which looks to the north, were the Cyzican triclinium, and the pinacœtheca; to the east the libraries; to the west the exhedræ; and in those looking to the south, were the square œci for dining, and a spacious place for the use of the games. This peristylium and part of the house were called andronitides, because here the men only were invited, without being accompanied by the women.

On the right and left small houses were erected for the reception and entertainment of strangers on their arrival.

The usual mode of distribution of the houses of magistrates among the Romans was; from the vestibulum, which we call portico, you entered the atrium or hall, at the extremity of which was the tablinum, or repository for books or records. From the sides of the atrium, you passed by alæ or aisles, to the cavædium, which was an open court, surrounded by a portico or piazza, at the extremity of which was the basilica or place to administer justice in. The triclinia or dining rooms, with their procœton, or room for attendants, the cubicula or chambers, with the baths, were disposed on the sides of the cavædium; also on the side of the basilica were the pinacætheca, or rooms for pictures and library. Passing all these apartments, you entered the peristylium, which was as spacious as possible, surrounded with a portico or piazza; this was always of an oblong form. At the extremity of the peristylium were the œci or halls, of which Vitruvius mentions the Corinthian, the tetrastyle, the Egyptian, and the Greek or Cyzican.

The Corinthian œci had columns placed either on the podium, dado, or on the floor, and above have an architrave and cornice; the Egyptian had the columns detached from the wall, in the manner of a peristyle: the space between the columns and the wall formed a walk round. This range of columns supported an entablature, on which was placed another range of columns, one fourth part smaller than the former, between which were the windows.

The Greek or Cyzican œci were situated toward the north, and generally had a view of the garden, with folding doors to the middle, and to the right and left. The tetrastyle œci, from the name, appear to have had only four columns, and were consequently of a less enriched form.

Roman villas consisted of three parts: urbana, where the master and his family dwelt; rustica, for the uses of husbandry; and fructuaria, or receptacle for the fruits of the earth. Having only the lapis specularis, a species of talc, and an expensive substitute for glass, the Romans were obliged to be very particular in the choice of situation and aspect for their buildings, that rooms unfurnished with this kind of expensive windows might be inhabitable in bad weather.

Vitruvius says the winter dining room and bath should face the winter's declining sun, that they may have the benefit of his rays in the evening; but the bedchambers and libraries should look to the east, for there the morning light is required, and south and west rooms are more exposed to damps and worms, which humid winds generate and nourish. The spring and autumn dining room should look to the east, for the windows being turned from the sun, these places will be temperate at the time they are used. The summer dining room should look to the north, that it may remain cool and temperate for use. To the same aspect, the pinacotheca, picture rooms, should be disposed, to preserve the colours from the too strong effect of the sun's light.

Some adequate idea of the extent, grandeur, and accommodation, of the villas of the Romans, may be formed from Pliny's description of his at Laurentinum, which was considered as on a small scale, but would be called a mansion in modern language. He says, "The part which first presents itself is the atrium, court yard, plain but not mean; then the portico, in form of the letter O, which surrounds a small but pleasant area: this is an excellent retreat in bad weather, being sheltered by glazed windows, but more by the projection of the roof. Beyond the portico is a pleasant cavædium, open court, passing which is a handsome triclinium, which advances upon the shore, so that it is gently washed by the waves when the southwest wind blows. On every side there are folding doors, or windows as large, so that from the sides and front you enjoy a prospect as it were of three seas, and backward are seen the cavædium, the portico, and the area; again the portico and atrium terminated by woods and distant mountains. On the left of the triclinium, but not so forward, is a large cubiculum, or chamber, and then a smaller one, where one window admits the rising, and another the setting sun. From here you view the sea, more distant, but more securely. This cubiculum and triclinium, by their projecture, form an angle, which not only retains, but augments, the heat of the sun's rays.

"Here is my hybernaculum, winter apartment, and the gymnasium, place for exercise, for my family, which is never incommoded by any winds but such as bring cloudy weather, and destroy the otherwise serene situation of the place. Adjoining to this angle is a cubiculum, of a curved or round form, the windows of which admit the sun, in consequence, during its whole course. In the walls are inserted library presses, furnished with books, more for amusement than study; close to this is the dormitorium, sleeping room, separated by a space having a covering of wood work, which collects and distributes the vapours to the room in salubrious temperament. The remainder of this wing is allotted to servants and slaves.

"On the right side of the triclinium is a most elegant cubiculum, with another large cubiculum, or moderate cœnation, common eating or supper room, which receives light both from the sun and the sea; after this is a cubiculum, with a procœton, servants' room, for height a summer, but for shelter a winter apartment, being screened from all winds: a wall only separates another cubiculum, with a procœton; there you enter the spacious and extensive cella frigidaria of the bath, against the walls of which are two projecting baptisteria, sufficiently large to swim in; joining this is the unctuarium, the hypocaustum, and propnigeon of the baths, and two other cells more elegant than sumptuous. Skilfully contrived adjoins the callida piscina, warm bath, where those who swim enjoy a view of the sea; not far distant is the sphræisterium, tennis court, of a circular form, which enjoys the warmest rays of the declining sun.

"Here rises a turris, pavilion or summer house, under which are two diætæ, suite or set of apartments, and also two above, besides a cœnatio, from which is a beautiful prospect of the sea; there is also another turris, containing a cubiculum, exposed to the rising and setting sun; behind this is an apotheca, and horreum, cabinets or store rooms, and under a triclinium, where the noise of the sea is only faintly heard in storms. This looks on the gestatio, or place of exercise on horseback or in a carriage, and the surrounding garden. The prospect here, not less pleasant than that of the sea, is enjoyed from a cœnatio, rather distant from the sea; on the back it is encompassed with two diætæ, whose windows look to the vestibule of the villa, and to a kitchen garden.

"Hence a crypto porticus, a long enclosed room or portico, extends, for size comparable to a public building, with windows on both sides, those next the sea the most numerous; on the garden side they are single, with fewer in the upper row. Before the crypto porticus is a xystus, a spacious place for exercise, or a terrace.

"At the top of the xystus, projecting from the crypto porticus, is the diæta of the garden. In this is an heliocaminus, an apartment made warm by the sun; from the folding doors is seen the cubiculum, from the windows the crypto porticus; on the side next the sea, and opposite the wall, a very elegant zotheca, closet or small room, recedes, to which a cubiculum is either added or separated, by means of glazed windows and curtains. Adjoining is a cubiculum for night and sleep, protected from noise by an andron, an open court or space, which is between the wall of the cubiculum, and that of the garden.

"Close to the cubiculum is a small hypocaustum, stove, the heat from which, by a small window, may be regulated at pleasure. Thence a procœton and cubiculum extend into the sun." These latter apartments were the retiring places of the philosophic owner of the villa, where he pursued his studies without interrupting the diversions of his servants, or being disturbed by them. There are no remains of this villa nor of others, the descriptions of which have come down to us.

REFERENCES TO THE PLATES.

Plate I. Architecture, represents the Tuscan and Doric orders, the latter with the triglyphs and guttæ on the frize and architrave, and an outline expressing the names of the parts of the orders.

Plate II. represents the ancient Ionic order, with parallel volutes. The disposition of the volutes of the modern Ionic is seen in those of the Composite order.

The Corinthian order.

The Composite order.

The proportions of these columns are treated of, under the proper heads in the preceding pages.

Of the architecture commonly called Gothic.

It is not necessary to seek abroad for the origin of the pointed arch, the gradations of which we can distinctly trace at home in the twelfth century, that age of improvement and magnificence, and among people great in arts and arms. About that time many illustrious Norman prelates, chiefly in our own country, exhausted their talents and their wealth in carrying the magnificence of their churches, and other buildings, to the highest degree. But above all, our Henry of Winchester probably contributed most to the improvements which gradually changed the early Norman into the architecture commonly distinguished by the name of Gothic.

The Normans admired height no less than length in the construction of their churches, and were accustomed to pile arches and pillars on each other. By way of ornament and variety they often imitated these arches and pillars on their walls, and they sometimes caused these plain round arches to intersect each other, as on the upper part of the south transept of Winchester cathedral, which is probably the most ancient instance of this intersecting ornament to be met with in this kingdom. They were probably not then aware of the happy effect of this intersection in forming the pointed or lancet arch, until de Blois, having resolved to ornament the whole sanctuary of this cathedral with these intersecting semicircles, after richly embellishing them with mouldings and pellet ornaments, conceived the idea of opening them as windows, to the number of four above the altar, and of eight on each side of the choir, which at once produced a series of highly pointed arches. Pleased with this first essay at the east end, we may suppose he tried the effect of that form in various other windows and arches, which we find amongst many that are circular in various parts of the church or tower. However that may be, and wherever the pointed arch was first produced, its gradual ascent naturally led to a long and narrow form of window and arch, instead of the broad circular ones which had hitherto obtained. It was necessary that the pillars belonging to them should be proportionally tall and slender. Hence the adoption of Purbeck marble for this purpose, and the multiplication of these slender columns, which was found necessary for sup-

porting the incumbent weight, produced the cluster column. The windows being made very narrow at the first adoption of the pointed arch, it became necessary sometimes to place two of them close to each other. This disposition of the two lights occasioning a dead space between their heads, a trefoil, or quatrefoil, one of the simplest and most ancient kinds of ornaments, was introduced between them, as in the west door of the present church of St. Cross, near Winchester. The happy effect of this simple ornament caused the upper part of it to be introduced into the heads of the arches themselves, so that there is hardly a small arch, or resemblance of an arch of any kind, from the days of Edward the Second, down to those of Henry the Eighth, which is not ornamented in this manner. The trefoil by an easy addition became a cinquefoil, and being made use of in circles and squares, produced fans and Catharine wheels. In like manner, large east and west windows beginning to obtain, about the reign of Edward the First, it was necessary they should have numerous divisions, or mullions, which, as well as the ribs and transoms of the vaulting, began to ramify into a great variety of tracery, according to the architect's taste; all of them uniformly ornamented with the trefoil or cinquefoil head. That most magnificent object, a grove of tall trees, was very naturally and beautifully imitated in the aisles of the cathedrals of this light architecture: the ribs of the vaulting, springing from the tops of the tall pillars, and meeting in the pointed arch in the roof, produced a happy effect; and pursuing this idea, the lightness of all the parts, and the rich variety of tracery, contributed to make the resemblance more perfect. The painted windows, the gloom and perspective of these edifices, concur in affecting the imagination with pleasure and delight, in filling it with awe and devotion. The aspiring form of the pointed arches, the lofty pediments, and the tapering pinnacles, which adorn our cathedrals, contribute to produce an effect of height beyond their real elevation. In like manner the perspective of uniform columns, ribs, and arches, repeated at equal distances, as they are seen in the aisles of these fabrics, produces an artificial infinite in the mind of the spectator, when the same extent of plain surface would perhaps hardly affect it.

For a similar reason, the effect of ancient cathedrals is greatly helped by the variety of their constituent parts and ornaments, though all finished in one uniform style: for the eye is quickly satiated by any object, however great and magnificent, which it can take in at once, as the mind is with what it can completely comprehend; but when the former, having wandered through the intricate and interminable length of a pointed vault in an ancient cathedral, discovers two parallel lines of equal length and richness; thence proceeding discovers the transepts, the side chapels, the choir, the sanctuary, and the Lady chapel, all equally interesting for their design and execution: the eye is certainly much more entertained, the mind more dilated and gratified, than it could possibly be by any single view.

Durham cathedral, supported by massive columns and circular arches, is the grandest specimen of the Saxon or early Norman manner, before the invention of the pointed arch introduced that exquisite lightness to be seen in the west end of the cathedral church of Westminster. The sumptuous vaulting of the chapel of Henry the Seventh at the east end of the latter cathedral, enriched with clusters of pendent ornaments, like the natural roof of a beautiful grotto, exceeds any other specimen of the kind.

The pointed arch, which may be described from two centres, taken at two angles of an equilateral triangle, was well adapted for the raising up of spires to a great height, and generally for lofty buildings, as it required little centering, lighter keystones, and less buttament. Indeed, in many instances, no stones larger than a man could carry were used; and the same elevation was attained with much less labour and expense than it could have been in the Grecian and Roman manner.

Of domes or cupolas.

The towers which the early architects of Christian churches were in the habit of raising over the intersection of the cross aisles of cathedrals, no doubt, suggested the sublime idea of raising a vault or dome in the same place, on churches built after the Grecian or Roman manner, in order to preserve an uniform character or style in the building. This is an effort of architectural skill which we have no reason to believe the ancients ever attempted; for all the domes raised by them were directly sustained by numerous arches and pillars, or placed on circular walls. Of domes raised in the modern manner, those of St. Peter's at Rome, and St. Paul's at London, are the most celebrated.

Of modern or practical architecture.

In considering architecture or building in its most practical and useful point of view, the situation of the edifice presents itself first to our attention. A neighbourhood where cattle thrive, and where the inhabitants look ruddy and cheerful, should be chosen. For the precise spot, that which is moderately elevated, if it be contiguous to some river, will be best adapted for health, pleasure, and convenience. It is injudicious to build a country house too near a fen or standing water, or close to a great stream, because unwholesome fogs and mists rise from large rivers, early in a morning, before daylight. It is most important to choose a good air and soil; and always useful to look toward the south. The conveniencies of water, fuel, and ways to arrive at the mansion, of easy access, are indispensable. A prospect not too extensive, of land and water diversified, will most agreeably entertain the sight. A fair entrance, with an easy ascent, gives grace to a building; and the hall should not be too large, that the effect of the capacity of the principal apartments may not be injured by it.

Having fixed on a situation with the assistance of some one who is acquainted with the theory and practice of building, let a plan be made, with the necessary elevations. For small buildings this may be a sufficient guide; but it is advisable for large buildings to have a perfect model of the intended structure, with all its minute parts; and that this model be plain, without colours, or other beautifying, that the pleasure of the eye may not prejudice the judgment.

In the choice of the materials we must employ, we are necessarily influenced by the circumstances of the situation. Where stone is plenty, it will be preferred in the construction of a stately edifice; for though bricks retain

their beauty longest, they do not easily admit of proper architectural ornaments.

The circular form of building is strongest, but does not admit of a convenient distribution of light; and is besides more expensive and less commodious. Though there exists at Caparole a celebrated building by Vignola, in the form of a pentagon, the same objections apply to it, and the architect had great difficulties to contend with.

A rectangular, but not exactly square figure, is useful in many cases: when the length does not exceed the breadth more than one third, the proportion is good.

Mixed figures, including uniformity and variety, are most applicable for the plans of large edifices: a centre and principal part with wings, is a form that combines convenience with elegance.

When houses are planned too long, much room is consumed in passages; and it is difficult to light them. Sir William Chambers, in the plan of Somerset house, has succeeded very well in lighting and disposing of the passages that were necessary for the easy communication of so many offices; but his methods will seldom be applicable, except to public buildings of the same nature.

Palladio says, the ground for the foundation should be penetrated to a sixth part of the whole height of the building, in order to ascertain its firmness; which done, the first course of stone or brick should be laid, at least twice the breadth or thickness of the wall, and on a horizontal line and level surface. If the building has internal walls, their foundations must be level with the principal wall. The nature and solidity of the soil will be best ascertained by the use of a well digger's borer.

If the ground is sandy, or marshy, or has been lately dug up, it will be necessary to take many precautions. The loose earth either must be dug away, till you come to sound ground; or if that is not to be had, put pieces of good oak across the breadth of the trench in which the wall is to stand, at about two feet apart, which being firmly bedded and rammed down, lay long planks on them, about four inches wider than the basis or first course of the wall is to be, and spike them down to the pieces of oak.

If the earth is very bad, it will be necessary to drive piles of such a length as will reach the good ground; but if it is faulty only here and there, arches may be turned over the loose places.

Sound ground, fit to carry a building, is of divers kinds; in some places very hard, in others very stiff: sometimes it is to be found blackish, and the whiter kinds are accounted the weakest. Some foundations are like chalk, others sandy: but of all these, that is the best which requires most labour in cutting or digging, and which when wet, does not quite lose all consistency.

In masonry, the stones must be so cut, as to lie in the same direction as they did in the quarry, in order that their strength and solidity may be fully employed; for if their position be changed, and they are placed vertically, they are apt to split; and the smallest crevice in the foundation will produce a great cleft in the superstructure of a building.

It is very useful always to lay a platform of good boards in the trench dug for the foundation; and quite necessary that the first course of stone or brick should be laid closely without mortar, for mortar corrodes the timber.

The walls should be of bound masonry or brick work, standing perpendicularly, with the heaviest materials lowest; and they must be judiciously diminished in thickness as they rise. Certain courses of more strength than the rest must be laid to help to sustain the fabric, should a faulty part give way: this is done by bond timbers in brick walls. Particular attention is necessary to make the angles firm, which is sometimes done in brick edifices with great neatness and effect, by building the corners of squared stones.

Walls, if not connected with others at right angles, or nearly so, as the partition or separating walls of a house stand in respect to the front, should have an angle set out of about two feet, at every twenty feet distance, which will make them stand firmer than if twice the materials had been used.

In building walls, the bricks should be laid, in summer as wet, in winter as dry, as possible; that in warm weather the mortar may not harden too fast, and in winter, care must be taken to protect them from rain, snow, and frost. They should be laid point and joint in the wall, as little as may be, that the whole may be well bonded together.

It is not advisable to raise any wall above eight feet high before the one adjoining be wrought up to it; but the front and party walls should be carried up as nearly as possible together.

When all the materials are ready, a good workman with his labourer will in one day lay 1000 or 1200 bricks. Walls are less solid when the joints of mortar are too large.

Of the apertures in the walls, doors should be mentioned first. External doors should be as few in number as possible, and seldom less than four feet and a half in breadth, in middling sized buildings, for the principal entrance. Double doors, having a sufficient space between them to allow them to open, are essentially useful in preserving the temperature of a house, and preventing the admission of cold winds.

The modern mode of uniting when necessary two or more principal rooms of a good house into one, on the occasion of entertainments, by throwing back the folding doors which separate them, is a very great improvement. For by this means a small house may have some part of the convenience and magnificence of the largest ones, with less expense of space and materials.

The hall or entrance, the dimensions of which are determined by the scale of the building, should always be furnished with a fireplace; and if it is connected with the staircase, the warmth produced there will tend very strongly and effectually to regulate the temperature of the whole house.

Of the stairs in sumptuous buildings, the steps should not be less than four, nor more than six inches high; not more than eighteen nor less than twelve inches broad; not less than six feet, nor more than fifteen feet long. In ordinary houses they may be somewhat higher and narrower, and they must be much shorter in general. But eight, or even seven inches, is too high for an easy ascent; and they ought never to be less than nine or ten inches broad, nor shorter than three feet. The steps should be laid somewhat sloping, or a little higher behind, which is found to diminish in some degree the apparent labour of ascending.

The construction and placing of the stairs is one of the most difficult works in building. Sufficient ease of ascent being obtained, the admission of an ample portion of light is a next consideration. This is obtained most advantageously in houses of a moderate size by windows at each turning, which give an uniform light, and a more airy and spacious appearance to the whole. Well stairs, lighted by a sky light in the roof, are only magnificent and convenient in large mansions, and for the ascent to the first or principal floor, where the light is not broken by a repetition of the flight of steps to the next story.

The small uniform modern ramp or hand rail is a very great improvement and addition to stairs, as well as the light iron work by which the rail is supported; this in many cases may be advantageously constructed of cast iron.

Ingenious architects have displayed their invention and their skill in the construction of stairs more curious than useful. Double and quadruple winding stairs have been built, rising in parallel spirals; so that two or four persons or companies may go up and down within the same staircase, and see one another without meeting.

It is an old fault in the distribution of lodging rooms, to dispose them so that, when the doors are all open, one may see through the whole house. The modern mode of placing a bed chamber and dressing room together, with a door of communication between them, each room having besides only a door into the staircase or passage, is much more convenient and rational. The drawing rooms however should be disposed so uniformly, as to be converted into one room, on the opening of folding doors between them. This contrivance, so useful in small buildings, is admissible in the largest. If two or more rooms thus laid into one, have in the middle of the wall at each end door cases filled with looking-glasses, placed in a true position opposite each other: the appearance of the apartment will be artificially multiplied, and the effect when illuminated very splendid.

This arrangement is not necessary for the dining rooms, where we have chiefly to attend to the convenience of easy access for servants who wait at table: and the fireplace may be so disposed, as to warm the room as uniformly as possible.

In the building of chambers regard ought to be had as well to the place of the bed, which is generally six or seven feet square, and the passage, as to the situation of the chimney; which for this consideration, ought not to be placed just in the middle, but distant from it about two feet, or two and a half, to the end that it may leave room for the bed; and the inequality is hardly discernible in buildings of four and twenty feet within the work; in such houses it may be placed just in the middle.

All precautions should be taken to prevent as much as possible the communication of sound to the bed rooms. To this end, the best method is to fill the space between the joints of the floor above the bed room, if there should be any rooms there, with sawdust; which must be sustained by short pieces of board nailed between the joists, just above the ceiling of the lower apartment.

In arranging servants' rooms, we have only to consult the facilities our general plan admits of; and, if possible, to make no chambers without fireplaces.

In country mansions, we are generally not confined in placing the kitchen, and have only to contrive it as near the dining apartment as other circumstances will admit; and to arrange it so that the effluvia produced by the cooking may not be inclined to penetrate to the dining room, by the covered passage, which should always form the communication between these two apartments.

But in town houses, the kitchen must always be beneath the parlour floor; and being nearer the dining room than we would place it in a country mansion, and on a lower level; the lighter, warmed air, charged with the smell of the various operations of cookery, is more apt to annoy us.

A separate funnel, like the kitchen chimney, carried up in the stack with the rest, and next to that of the kitchen, will almost always afford an effectual remedy against this inconvenience. This funnel, to be used only for this purpose, must have its throat or opening level with the ceiling of the kitchen; and, of course, higher than the mantle of the fireplace used for the cooking. The lighter air charged with the vapours of the cooking will then pass off into the atmosphere by this opening, instead of collecting under the ceiling in the kitchen, and forming a stratum of air, as low as the top of the kitchen door, and then passing off, and ascending through the house by the stairs and passages. The opening of this funnel or pipe may be closed by a hinged door, when no operation is going on in the kitchen, which can create a disagreeable smell.

The modern improvement of traps, made of cast iron and other materials, or pipes bent down, so as to form an elbow, which always contains and is filled in its whole diameter by, the last portion of fluid thrown down, effectually prevents the ascent of air charged with the noisome effluvia of drains, and courses for waste water. This neater invention renders superfluous the advice of the Italian builders, who prescribe upright vents or channels rising through the house like chimnies for carrying off these smells. Upon this principle is the invention of water closets, which are now brought to such perfection, that they may be placed without inconvenience in any necessary part of a house, and are subject to no accidents except the bursting of the water pipes and basin belonging to them in frosty weather. But this danger may be, in some degree, removed, provided the whole building is planned with due attention to the economical distribution of heat, and the pipes are so disposed as to receive the benefit of the warmth; which may easily be done.

The offices connected with the kitchen should generally be placed toward the north; in town houses we cannot always do this, but are governed by the circumstances of the situation. The larder should however be carefully placed out of the influence of the heat of the kitchen stoves.

In the plan and construction of fireplaces, more attention should be paid to their best form for reflecting into the apartments the heat generated in them, and carrying off into the atmosphere the smoke which arises from the combustion of the fuel, than to any proportions prescribed by architects who had nothing in view but the symmetry of the apartment according to their ideas. Indeed a neater form may be obtained in following strictly the rules founded on the rational theory, and accurate experiments of the count Rumford; and the invention of a good architect will hardly stumble, at making that low

compact dimension agree with the other members of the most magnificent apartment.

The due inclination of the inner sides of the jambs of the chimney, forming a very obtuse angle with the back, is most important, as well as the colour and material of which those jambs are composed, for the purpose of obtaining as much reflected heat as possible from the combustion of a certain quantity of fuel. The breadth of chimney fireplaces is not important, but they should not be narrow, that the sides may stand with their greatest power of reflection toward the room. But the height should seldom exceed two feet six inches to the under part of the mantle; the whole depth of the chimney should not be more than twelve or fourteen inches; and the throat, or opening where the funnel begins, not more than four inches wide, with a part of the back moveable to allow of sweeping. The size of the flue or funnel should not be less than twelve inches in diameter; and circular is the best form, but most expensive in building. The flues should never contract or taper as they rise, but rather increase in internal capacity; and they should always be made with a view to the use of the new machinery for sweeping, approved of by the Society of Arts, and confirmed by experience. Stone and brick are the best possible materials for the sides and the back of a chimney fireplace. Architects however do not always think it a part of their business, or their duty, to enter into the arrangement of these details, relative to the internal comfort of a building. If it were not so necessary to harmonize the whole together, they present field enough for a separate profession; but the possibility of completing these essential, though minute parts, upon the principles of true philosophy and experience, with a view to economy and comfort, will in great measure depend on the general plan of the building.

Besides the precaution of double external doors, to preserve the internal temperature of a house, double windows, with a certain space between, should be used to winter apartments; for it is no less useful to confine the heat generated by the fuel consumed in a house, than it is to place it so that it shall give out in the apartments its full portion of warmth.

It is hardly necessary to say that windows should be made perpendicularly one above another, and not too near the angles of a building. No particular proportions can be assigned for them; but their jambs should be bevelled off on the inside, so that the full benefit of the real size of the window may be received, in light spread over the apartment. A window so expanded will admit to diffuse in the room as much light as if its whole internal size had been equal to its increased inner breadth, gained by cutting off the right angular corner of the wall.

Till lately architects have neglected to avail themselves, by this means, of the full benefit of the openings of their windows, and to admit as much light as possible, with as little diminution of strength to the wall. The immense thickness of the walls of old Gothic edifices generally obliged the ancient architects to do it; but in the more modern brick buildings, which succeeded, it was omitted.

Lofty windows, descending nearly to the floor, are most graceful, noble, and airy; and balconies, railed with cast iron for buildings not of the most superb class, are a very great ornament and convenience. Balusters of stone may agree more than iron railings for these projections, where the ornaments of the front are bold and solid.

Sky lights, in our climate, so subject to damps, driving rains, and to snow, are productive of many inconveniencies, and should never be admitted but for stairs, halls, passages, or large public rooms. Unless they are doubled by a horizontal frame of glass beneath them, to produce a cavity of confined air, they waste the heat generated in a house very much; as without this precaution the warmed air of the house escaping directly upward to the glass, easily mixes its acquired heat with the cold external air of the atmosphere. To which operation a single pane of glass, however thick, though glass is a bad conductor of heat, affords but little retardation.

When sky lights are necessary, the apertures through the roof should spread as much as possible in descending, that the rays of light may not be confined from spreading as they would be were the sides vertical.

For the form and proportion of rooms, we may observe that an oblong plan is most agreeable to the eye, and generally more convenient than a square, or any other form. The length of a well proportioned room should be equal to the breadth and a half of the same, and never more; and for the height, take three fourths of the breadth. An error in favour of height is preferable to making a room too low.

The height of rooms on the second story may be one twelfth part less than that of the chambers below; and if there is a third story, divide the height of the second into twelve equal parts, of which take nine for the height of these rooms.

The length of galleries may be five times their breadth; and a gallery should rarely exceed eight times its width in length.

When the walls of a building have been raised to the desired height, the vaults made, the joists laid, and the stairs brought up, then the roof is to be raised; which embracing every part of the building, with its weight equally pressing upon the walls, acts as a band to all the work. Its weight, within certain limits, is of service to the building; but too much charge will make a house top heavy, which is a great fault.

The pitch of a roof is regulated according to the climate we build in, and the materials employed to defend the timbers from the weather. Roofs covered with lead may be nearly flat: but this method is not much in use, and is very expensive. For tiles a roof must be higher than the pediment pitch, which is one fourth of the whole building. This pitch is rarely high enough for slates. Copper coverings have lately come much into use in this country, and may be laid on roofs of a low pitch.

Whoever plans a building to be erected within the limits of the building act, must necessarily consult it before he can arrange his design.

ARCHITECTURE, *aquatic*. See BRIDGE.

ARCHITECTURE, *military*. See FORTIFICATION.

ARCHITECTURE, *naval*. See SHIP BUILDING.

ARCHITECTURE, *counterfeit*: that which consists of projectures, painted in black or white, or in colours, after the manner of marble, which is also called scene work in the painting of columns, &c. for the decoration of theatres.

ARCHITECTURE, in perspective, a sort of building, the members of which are of different modules, and diminish proportionably to their distance, in order to make the work appear longer to the view than it really is.

ARCHITRAVE, in architecture, that part of a column, or order of columns, which lies immediately upon the capital, being the lowest member of the entablature, and so called from its representing the principal beam in timber buildings. Over a chimney, this member is called the mantlepiece; and over doors or windows, the hyperthyron.

ARCHIVE, or archives, an apartment in which are deposited the records, charters, and other papers, of a state or community. The archives of the court of chancery are in the rolls office.

ARCHMARSHAL, the grand marshal of the empire, a dignity belonging to the elector of Saxony.

ARCHON, in Grecian antiquity, the chief magistrate of Athens, after the abolishing of monarchy; and also the appellation given to several officers, both civil and religious, under the Greek empire. Thus we read of the archon of the Gospel, the archon of the walls, &c.

ARCHONTICI, in church history, a branch of Valentinians, who maintained that the world was not created by God, but by angels called archontes.

ARCHTREASURER, the great treasurer of the German empire, a dignity belonging to the duke of Brunswic, king of Great Britain, but also claimed by the elector palatine.

ARCTIC, in astronomy, an epithet given to the north pole; and likewise to a circle of the sphere, parallel to the equator, and 23 degrees 28 minutes distant from the north pole.

ARCTIUM, burdock, a genus of the polygamia order, and syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ capitatæ: the calyx is globular, with scales having hooks reflected at the tops. There are three species, *viz.*

1. Arctium lappa; 2. Arctium personata; and, 3. Arctium tomentosum. They are all troublesome weeds. The tender stems of the lappa, or common burdock, however, deprived of the bark, may be boiled and eaten like asparagus. When raw, they are good with oil and vinegar. Boys catch bats by throwing the prickly heads of this species into the air. The seeds, which have a bitterish subacrid taste, are recommended as very efficacious diuretics, given either in the form of emulsion, or in powder, to the quantity of a drachm. The roots, which taste sweetish, with a slight austerity and bitterishness, are esteemed aperient, diuretic, and sudorific; and said to act without irritation, so as to be safely ventured upon in acute disorders.

ARCTOMYS, marmot, a genus of quadrupeds. The generic character is; front teeth two in each jaw, strong, sharp, and cuneated; grinders in the upper jaw five on each side, in the lower jaw four; clavicles, or collar bones, in the skeleton. The genus arctomys or marmot differs from that of mus in so few particulars, as to make it somewhat doubtful whether it ought to be kept separate or not. These animals are of a thick form, with large, roundish, and somewhat flattened heads, small mouths, the fissure having a somewhat perpendicular appearance: ears very short, and sometimes none; a short villous tail; tetradactyle fore feet, with a very small thumb, and pentadactyle hind feet: the skeleton is furnished with clavicles, or collar bones; and the cæcum or appendicular intestine is very large. They are diurnal animals; and feed on roots, grain, &c. which they often collect into heaps. They reside in subterraneous holes or burrows, and sleep during the winter. There are 7 species, as follows.

1. Marmot alpine is a native of the Alps and Pyrenean mountains, and is most frequent in those of Savoy and Switzerland, inhabiting the higher regions, and feeding on various roots, plants, insects, &c. It climbs readily, and can ascend the rocky eminences and fissures with great facility. Its general size is somewhat larger than that of a rabbit, measuring about 16 inches to the tail, which is about six inches long. The colour of the marmot, on the upper parts, is a brownish or rather tawny ash colour; the legs and under parts being of a bright tawny or ferruginous tinge; the head is rather large, and flattish; the ears short, and hid in the fur, and the tail thick and bushy. It is an animal which delights in the regions of frost and snow, and is found only on the tops of high mountains. In such situations several individuals unite in forming a place of retreat, which is contrived with great art, and consists of an oval cavity or general receptacle, large enough to contain several of the animals, and having a large canal or passage, which divaricates in such a manner as to present two outlets to the surface of the ground. These recesses are prepared on the declivities of elevated spots, and the cavern or receptacle is well lined with moss and hay, which they prepare during summer, as if conscious of the necessity of providing for their long hybernal sleep. In fine weather they are seen sporting about the neighbourhood of their burrows; and delight in basking in the sunshine, frequently assuming an upright posture, sitting on their hind feet. When assembled in this manner, it is observed, that one of the exterior number seems to act as a sentinel, and on the approach of any danger, alarms the fraternity by a loud and shrill whistle, on which they instantly retire to their cavern. These animals make no provision for winter; but as soon as the autumnal frosts commence, they carefully stop up the entrances to their mansions, and gradually fall into a state of torpidity, in which they continue till the arrival of spring, when they again awake, and recommence their excursions. Before they retire to their winter quarters they are observed to grow excessively fat; and, on the contrary, appear greatly emaciated on first emerging from them. If carefully dug up during the winter, from their holes, they may be conveyed away in their sleeping state; and when brought into a warm chamber, gradually awaken, nearly in the same manner as the hamster. If kept in a warm situation, they do not become torpid in winter. They breed early in the summer, and the litter commonly consists of three or four, the growth of which is observed to be very rapid. See Plate X. Nat. Hist. fig. 33.

2. Marmot Maryland is a North American animal, and is principally found in Virginia and Pennsylvania. It also occurs in the Bahama islands; and in its way of life resembles the European or Alpine marmot, living on vegetable substances, retiring into hollows under the roots of trees, &c. in winter, and falling into a temporary state of torpidity; it is doubtful, however, whether this is the case in those which are found in the Bahama islands. The size of this species is nearly that of the rabbit; its colour is a fer-

ruginous brown above, and paler or inclining to whitish beneath; the muzzle, as far as the eyes, is of a pale bluish ash colour; the ears are short and rounded; the eyes are rather large and black, and the snout sharpish; the tail is longer than in others of this genus, being nearly half the length of the body, and covered with longish or rather bushy hair, of a deep brown or blackish colour; the feet are blackish, and are furnished with large and sharp claws.

3. Marmot Quebec is said to be found in various parts of North America, but it appears to be most frequent in Hudson's bay and Canada. Its size is that of a rabbit, or rather larger, and its colour is brown on the upper parts, undulated with whitish or pale gray, the tips of the hairs being of that colour; the legs and under parts of the body are rufous or ferruginous; the face is dusky; the nose black and obtuse, the cheeks gray, and the tail short and dusky, especially at the tip. In its manners it is supposed to resemble the rest of its congeners.

4. Arctomys bobac. See Plate X. Natural History, figure 32. The bobac is of the size of the Alpine marmot, and is a native of the high but milder and sunny sides of mountainous countries, which abound with fissile or freestone rocks, where it is found in dry situations, and such as are full of springs, woods, or sand. It abounds in Poland and Russia, among the Carpathian hills. Its colour is gray above, with the throat, insides of the limbs, and under parts of the body, fulvous or ferruginous; the tail is short, rather slender, and full of hair. Its manner of life extremely resembles that of the common or Alpine marmot, with which, indeed, it appears to have been sometimes confounded by naturalists. The holes or receptacles of these animals are lined with the finest hay, and it is said that the quantity found in one nest is sufficient for a night's provender for a horse. They are fond of sporting about in the sunshine near their holes, like the common marmot, set up a similar whistle when disturbed, and retire with precipitation to their receptacle. They may be easily rendered domestic, like that species, and are of a mild and gentle disposition. In winter they lie torpid, unless kept in warm rooms. They breed early in the spring, and are said to produce six or eight young.

5. Arctomys pruinosa, or hoary marmot. This species is about the size of the monax, or Maryland marmot, and is of a hoary ash colour; the hair, which is long and rather coarse, being cinereous at the roots, black in the middle, and white at the tips; the tip of the nose, legs, and tail, are black; the cheeks whitish, and the top of the head dusky, with a ferruginous cast. It is a native of North America.

6. Arctomys maulina, or mauline marmot. This animal was discovered in the province of Maule, in Chili, where it inhabits woods. It is said to be about twice the size of the common or Alpine marmot, nearly of the same colour, but has pointed ears, lengthened nose, four rows of whiskers, and a longer tail than the common marmot. On each foot are also said to be five toes. It is represented as a strong animal, and not easily conquered by dogs which happen to attack it.

7. Arctomys gundi, or gundi marmot. This species is a native of Barbary, toward mount Atlas, near Masuffin. It is about the size of a small rabbit, and is entirely of a testaceous red colour; the ears are truncated, with large apertures; the tail short, the upper teeth truncated, and the lower slender and pointed. It is called by the Arabs gundi. Its particular history seems as yet to be not fully understood.

Arctomys citillus, or variegated marmot. Of all the marmots this is the most elegant in its appearance, exhibiting generally a beautiful variegation of yellowish brown and white, the former constituting the ground colour, and the latter the variegations, which are sometimes in the form of spots, and sometimes of transverse undulations; the legs and under parts of the body are of a yellowish white; the tail is short, well covered with hair, and is brown above and ferruginous beneath: there is scarce any appearance of external ears, but merely an edging to the auditory canal. The length of the animal is about a foot, and of the tail four inches and a half; but this species varies as much in size as in colours, some of the varieties are scarce larger than a water rat, while others are nearly equal in size to the marmot.

The variegated marmot inhabits Bohemia, Austria, Hungary, and from the banks of the Volga to India and Persia, through Siberia and Great Tartary to Kamtschatka, some of the intervening isles, and even the continent of America. It is sometimes found in woods, but seems principally to delight in dry hilly places, where the herbage is of short growth. They form subterraneous burrows, in which they deposite heaps of grain, roots, nuts, &c. for their winter food; for it does not appear that they sleep during that period, like some others of this genus. They breed in the spring, and produce from five to eight at a time. They are extremely irascible and quarrelsome among themselves; their bite is very severe. They are extremely cleanly, and after feeding, generally wash their faces, like cats, and clean their fur with the greatest diligence.

ARCTOPHYLAX, a constellation, otherwise called boötes.

ARCTOPUS, in botany, a genus of the polygamia dioecia class and order, and in the natural method ranking under the 45th order, umbellatæ. The umbella of the male is compound; the involucrum consists of five leaves; the corolla has five petals; the stamina are five; and two pistilli; the umbella of the hermaphrodite is simple; the involucrum is divided into four parts, is spinous, large, and contains many male flowers in the disk. There is but one species of arctopus, *viz.*

Arctopus echinatus, a native of Ethiopia.

ARCTOTIS, in botany, a genus of the polygamia necessaria order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ discoites. The receptacle is bristly; the corona of the pappus is pentaphyllous; and the calyx is imbricated with scales loose at the top. There are 11 species; natives of Ethiopia, or the Cape of Good Hope. Of these,

1. Arctotis angustifolia, with spear shaped leaves; and
2. Arctotis aspera, with wing shaped woolly leaves, are most remarkable for their beauty. They are treated with us as green house plants.

ARCTURUM, a small star, of the seventh or eighth magnitude to the south of arcturus.

ARCTURUS, a fixed star of the first magnitude, in the skirt of boötes.

ARCTUS, in astronomy, the Greek name for the ursa major and minor, whence the words arctic, arctic circle, &c.

ARCUATION, in gardening, the raising of trees by layers, which is done thus: strong mother plants, or stools, must be planted in a clean border, and when they have shot five or six main branches from the root, and as many collateral branches, these main branches must be bent to the ground; for which reason, some cut them half through, and peg them fast down. The small branches must be covered three inches thick upon the joints, and have a large basin of earth made round them to hold the water. Some persons give the branches a twist, to make them root the sooner.

ARCUTIO, a machine consisting of hoops used in Florence by nurses, in order to prevent the child from being overlaid. Every nurse is obliged to lay her child in an arcutio, under pain of excommunication.

ARDASSES, the coarsest of all the silks in Persia.

ARDEA, the heron, a genus of the order of grallæ. The general characters of this order are; the bill is straight, sharp, long, and somewhat compressed, with a furrow that runs from the nostrils toward the point; the nostrils are linear, and the feet have four toes. Under this genus Linnæus comprehends the grus or crane, the ciconia or stork, and the ardea or heron. There are 79 species, of which the following are the most remarkable.

1. Ardea Americana, or hooping crane of Edwards, is a native of America. The crown of the head and temples are naked and papillous; the forehead, nape of the neck, and prime wing feathers, are black, but the body is white. This species is often seen at the mouths of the Savanna, Aratamaha, and other rivers near St. Augustin. They lay two white eggs, like those of the swan, and sit 20 days; the young are at first yellow, changing to white by degrees.

2. Ardea argil, or hurgil, of Ives, is a very large species; from tip to tip of the wings, measuring 14 feet 10 inches, and from the tip of the bill to the claws 7 feet and a half; the bill is 16 inches round at the base, of different colours, and nearly of a triangular shape; the feathers of the back and wings are of an iron colour, those of the breast long; over the belly a great deal of down, of a dirty white; the legs and half the thighs are naked; the naked parts full three feet in length. This monster inhabits Bengal. On opening one of these, a terrapine, or land tortoise, 10 inches long, was found in its craw, and a large male black cat was found entire in its stomach. One of these, a young bird, about five feet in height, was brought up tame, and presented to the chief of the Bananas, where Mr. Smeathman lived; and being accustomed to be fed in the great hall, soon became familiar, duly attending that place at dinner time, and placing itself behind its master's chair, frequently before any of the guests entered. The servants were obliged to watch it narrowly, and defend the provisions with switches in their hands; but notwithstanding this, it would frequently snatch off somewhat; and it once purloined a whole boiled fowl, which it swallowed in an instant. The individual above mentioned used to fly about the island, and roost very high among the silk cotton trees, whence at two or three miles distance it could spy the dinner carrying across the yard, when, darting from its station, it would enter promiscuously with the women who carried in the dishes. It sometimes stood for near half an hour after dinner, with the head turning alternately, as if listening to the conversation.

3. Ardea ciconia, or white stork of Ray, has naked eyeballs, and black prime wing feathers. The skin below the feathers, as also the beak, feet and claws, are of a blood colour. It is a native of Europe, Asia, and Africa, and feeds upon amphibious animals. It is such an enemy to serpents, that it is reckoned almost a crime to kill a stork. From this favourable treatment, they are seen in Holland and the Low Countries walking unconcerned in the middle of the streets. Storks are birds of passage; they spend the summer in Europe, go off to Egypt, Ethiopia, &c. all at once before winter, and do not return till about the middle of March.

4. Ardea garzetta, or egret, is crested behind; the body is white, the beak black, and the feet greenish. It is a most elegant bird. It weighs about one pound, and the length is 24 inches, to the end of the legs 32. It is a native of the east. But that formerly it was very frequent in Britain, appears by some of the old bill of fare. In the famous feast of archbishop Neville, we find no less than a thousand asterides, egrets or egrettes, as the word is differently spelled.

5. Ardea grus, or common crane of English authors, has a naked papillous crown; the prime feathers of the wings are black; the body is ash coloured. This species is far spread, being met with in great flocks throughout northern Europe and Asia. It seems to have been formerly a native of Britain. They feed on reptiles of all kinds, as well as on green corn, which last they make such havock of, as to ruin the farmers wherever flocks of them alight.

6. Ardea herodias, or cristata maxima of Catesby, is crested behind, has a dusky coloured back, reddish thighs, and the breast speckled with oblong black spots. It is four feet and a half when erect. It is a native of Virginia, and feeds upon fish, frogs, lizards, eels, &c.

Ardea leucogeranos of Pallas, or the Siberian crane of Pennant, is four feet and a half when standing erect. The bill is of a red colour; the irides are white; the plumage is white as snow, except the ten first greater quills, with the coverts of them, which are black; the legs are long and red. This species inhabits the vast marshes and lakes in Siberia. It makes its nest among the reeds, seldom accessible by man, upon rising green grassy tufts, made up of herbs and grass heaped together; and lays two ash coloured eggs, spotted with brown. They are shy birds, and always upon their guard against an enemy; having a sentinel to warn them of an approach; on the least alarm they cry aloud, not unlike the swan, and fly off directly. The sportsman finds, in course, much difficulty in approaching them. Sometimes indeed he approaches them under the cover of a stalking horse, or other objects; at other times a small dog will divert their attention, as they will without fear attack the dog, while his master gets within reach. In breeding time, however, they are more bold, as they will then defend their young even against men.

8. Ardea major, or common heron, has a black crest depending from the back part of the head, an ash coloured body, and a black line and belt on the neck and breast. It is a native of Europe. It perches and builds in trees, and sometimes in high cliffs over the sea, commonly in

company with others, like rooks. It was formerly in this island game, heron hawking being a favourite diversion of our ancestors. Not to know the hawk from the heronshaw was an old proverb, since absurdly corrupted to 'He does not know a hawk from a handsaw,' taken originally from this diversion, but in course of time served to express great ignorance in any science. This bird was formerly much esteemed as food; made a favourite dish at great tables, and was valued at the same rate as a pheasant. It is said to be very long lived; by Mr. Keysler's account it may exceed 60 years.

9. Ardea pavonia, or the crowned crane, has an erect bristly crest, with the temples and two wattles naked. It is a native of Africa, particularly of the coast of Guinea, as far as Cape Verd; at this last place they are said to be exceedingly tame, and will often come into the court yards to feed with the poultry. Their chief food is supposed to be worms, and such other insects as the heron tribe usually feed on, with vegetables of all kinds. See Plate X. Nat. Hist. fig. 34.

10. Ardea stellaris, or the bittern, has a smooth head, and is variegated through the body with dark coloured spots of different figures and sizes. It is a native of Europe, and inhabits the fen countries. It will suffer persons to come very near it without rising, and has been known to strike at boys and at sportsmen, when wounded and unable to make its escape. It flies principally about the dusk of the evening, and then rises in a very singular manner, by a spiral ascent, till it is quite out of sight. It builds its nest with the leaves of water plants on some dry clump among the reeds, and lays five or six eggs of a cincrous green colour. This bird and the heron are very apt to strike at the fowler's eyes when only maimed. The food of the bittern is chiefly frogs; not that it rejects fish, for small trouts have been met with in their stomachs. In the reign of Henry VIII. it was held in much esteem at our tables, and valued at one shilling. Its flesh has the flavour of a hare, and nothing of the fishiness of that of the heron.

11. Ardea violacea, or crested bittern of Catesby, has a white crest; the body is variegated with black and white, and bluish below. These birds are seen in Carolina in the rainy seasons; but in the Bahama islands they breed in bushes growing among the rocks in prodigious numbers. They are called by the Bahamians crab catchers, crabs being what they mostly subsist on; yet they are well tasted, and free from any rank or fishy savour.

12. Ardea virgo, has a straight greenish bill and crimson irides. The crown of the head is ash coloured; the rest of the head, the upper, and all the under parts, to the breast, black; the back, and all the under part from the breast, of a bluish ash colour; behind each eye springs a tuft of long white feathers, which decline downward. It is found in many parts of Asia and Africa. See Plate X. Nat. Hist. fig. 35.

ARDENT spirits, those distilled from fermented vegetables, so called because they will take fire and burn, such as brandy, rum, &c.

ARDISIA, a genus of the tentandria monogynia class and order. The essential character is, calyx five class, corolla one petalled, five parted, reflex, stigma simple, berry round, one seeded.

There are seven species, all trees or shrubs, chiefly natives of the West Indies.

ARDUINA, a genus of the pentandria monogynia class and order. The essential character is; corolla one petalled; stigma bifid; berry two celled; seeds solitary. There is one species, a native of the Cape, which with us is treated as a green house plant.

AREA, in geometry, denotes the superficial content of any figure: thus, if we suppose a parallelogram six inches long, and four broad, its area will be $6 \times 4 = 24$ square inches.

The method of finding the areas of different figures, as triangles, circles, &c. will be given hereafter.

ARECA, the Fausel nut in botany, a genus of the order of the palmæ pennatifoliæ. The male has no calyx, but three petals, and nine stamina: the female has no calyx; the corolla has three petals, and the calyx is imbricated. There are three species, *viz.*

1. Areca cathecu, a native of India. It has no branches, but its leaves are very beautiful; they form a round tuft at the top of the trunk, which is as straight as an arrow. It grows to the height of 25 or 35 feet, and is a great ornament in gardens. The shell which contains the fruit is smooth without, but rough and hairy within; in which it pretty much resembles the shell of the cocoa nut. Its size is equal to that of a pretty large walnut. Its kernel semblance without, and has also the same whitish veins within when cut in two. In the centre of the fruit, when it is soft, is contained a grayish and almost liquid substance, which grows hard in proportion as it ripens. The extract of this nut has been supposed to be the terra japonica of the shops: but according to later observations, the genuine drug seems to be obtained from the mimosa catechu. The fruit when ripe is astringent, but not unpalatable, and the shell is yellowish. Of this fruit there is a prodigious consumption in the East Indies. The chief use that is made of it is to chew it with the leaves of betel, mixing with it lime made of sea shells.

2. Areca oleracea, Plate X. Nat. Hist. fig. 36, or true cabbage palm, is the most beautiful, and perhaps the tallest, of all trees. The trunk is perfectly straight, and marked with rings at the vestigiæ of the footstalks of the leaves. Near the ground it is about seven feet in circumference; but tapers as it ascends, and attains the height of 170 or 200 feet. The bark is of an ash colour, till within 25 or 30 feet of the extremity of the tree; when it alters at once to a deep sea green, which continues to the top. About five feet from the beginning of the green part upward, the trunk is surrounded with its numerous branches, in a circular manner; all the lowermost spreading horizontally with great regularity; and the extremes of many of the higher branches bend wavingly downward, like so many plumes of feathers. These branches, when full grown, are 20 feet long, more or less; and are thickly set on the trunk alternately, rising gradually superior one to another: their broad curved sockets so surround the trunk, that the sight of it, whilst among these, is lost, which again appears among the uppermost branches, and is there enveloped in an upright green conic spire, which beautifully terminates its great height. As there are many thousand leaves upon one tree, every branch bearing many scores upon it, and every leaf being set at a small and equal distance from one another, the beauty of such a regular lofty group of waving foliage, susceptible of motion, by the most gentle gale of wind, is not to be described. The middle rib, in each leaf, is strong and prominent,

supporting it on the under side, the upper appearing smooth and shining. The pithy part of the leaf being scraped off, the inside texture appears to be so many longitudinal threadlike filaments. These, being spun in the same manner as they do hemp, or flax, are used in making cordage of every kind. Upon removing the large leaves, or branches, which surround the top of the trunk, a little way above the beginning of the green bark, what is called the cabbage is discovered lying in many thin, snow white, brittle flakes, in taste resembling an almond, but sweeter. This substance, which cannot be procured without destroying the tree, is boiled, and eaten with mutton by the inhabitants of the West Indies, in the same manner as turnips and cabbage are with us. What is called the cabbage flower, grows from that part of the tree where the ash coloured trunk joins the green part already described. Its first appearance is a green husky spatha, growing to above 20 inches long, and about four broad. As this husky spatha is opening while thus young, the farinaceous yellow seed in embryo, resembling fine sawdust, is very plentifully dispersed among stringy filaments, which answer the use of apices in other more regular flowers: these filaments being cleared of this dust, are pickled, and esteemed among the best pickles either in the West Indies or in Europe. But if this spatha is not cut down and opened whilst thus young; if it be suffered to continue on the tree, till it grows ripe and bursts; then the enclosed part, which whilst young and tender is fit for pickling, will by that time have acquired an additional hardness, become soon after ligneous, grow bushy, consisting of very small leaves, and in time produce a great number of small oval thin shelled nuts, about the size of unhusked coffee berries: these, being planted, produce young cabbage trees. The sockets or grooves, formed by the broad part of the footstalks of the branches, are used by the negroes as cradles for their children. On the inner side of the very young footstalks are tender pellicles, which when dried, it is said, make a writing paper. The trunks serve as gutterings; the pith makes a sort of sago; and the nuts yield oil by decoction. In the pith also, after the trees are felled, there breeds a kind of worm or grub, which is eaten and esteemed a great delicacy by the French of Martinico, St. Domingo, and the adjacent islands.

3. Areca oryzæformis. This is a native of Cochin China, Amboyna, &c. It is a slender elegant palm, and the fruit is used for chewing with the betel leaf as well as that of the first species.

ARENA, in Roman antiquity, a place where the gladiators fought: so called from its being always strewed with sand, to conceal from the view of the people the blood spilt in the combat.

ARENA, in architecture, the middle or body of a temple, that comprehends the whole space between the antæ, and the extreme wall of the building.

ARENARIA, in ornithology, called the turnstone or sea dotterel by English writers; also a species of tringa that inhabits the sandy shores of Europe and the Caspian Sea.

ARENARIA, in botany, sandwort: a genus of the decandria trigynia class; and in the natural method ranking under the 22d order, caryophyllæ. The calyx has five open leaves; the petals are five and entire; the capsule is unilocular, and contains many seeds. There are 20 species, only seven of which are natives of Britain, *viz.*

1. Arenaria laricifolia, larch leaved sandwort.
2. Arenaria peploides, sea sandwort.
3. Arenaria rubra, purple flowered sandwort.
4. Arenaria saxatilis, mountain sandwort.
5. Arenaria serpyllifolia, least sandwort.
6. Arenaria tenuifolia, fine leaved sandwort.
7. Arenaria trinervis, plantain leaved sandwort.

ARENARII, in antiquity, gladiators who combated with beasts in the arena or amphitheatre. They were slaves of the lowest order, and not capable of becoming Roman citizens.

ARENARIUM, a cemetery or burying ground. The arenaria were a kind of pits in which the ancient Christians buried their dead, and held their religious assemblies in times of persecutions.

ARENARIUS, in ornithology, a species of tetrao, called also the sand grous, found only in the deserts toward the Caspian Sea. It is common about Astrachan in summer, and passes the winter in Persia. They drink much water, and go to the pools thrice every day; when they are so eager, that they do not mind the sportsmen, though at other times they are very shy.

ARENATION, a kind of dry bath, in which the patient sits with his bare feet on hot sand.

AREOPAGUS, or Aræopagus, in Grecian antiquity, a sovereign court at Athens, so famous for the justice and impartiality of its decrees, that the gods themselves are said to have submitted their quarrels to its determination.

ARETHUSA, in botany, a genus of the gynandria diandria class; and in the natural method ranking under the seventh order, orchideæ. The generic character is taken from the nectarium, which is tubular, situated at the bottom of the corolla, and the inferior labium fixed to the stylus. There are seven species, all natives of America.

ARETIA, in botany, a genus of the pentandria monogynia class; and in the natural method ranking under the 21st order, pretiæ. The corolla is divided into five parts; the tube of the corolla is ovated; and the capsule is globular, and consists but of one cell. There are three species.

ARGEA, or Argei, in Roman antiquity, thirty human figures, made of rushes, thrown annually by the priests, or vestals, into the Tiber, on the day of the ides of May.

ARGEMONE, prickly poppy, a genus of the monogynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 27th order, rhœadeæ. The corolla consists of six petals; the calyx is tryphillous; and the capsule is semivalved. Of this genus there are three species, one of which is common in many parts of the West Indies, and called by the Spaniards the devil's fig; but they are of no use, and have very little beauty.

ARGENT, in heraldry, the white colour in the coats of gentlemen, knights, and baronets: the white in the arms of the sovereign princes is called luna, and that in the arms of the nobility, pearl: this is expressed in engraving, by the parts being left plain, without any strokes from the graver. See HERALDRY.

ARGENTEUS, *codex*, a MS. of the four Gospels, that derives its name from its silver letters, supposed to be a copy of the Gothic version made by Ulphilas, the apostle of the Goths, in the fourth century. It is 4to. the leaves violet colour parchment; and on this ground the letters, which are all capitals, were painted in silver, except

the initials, and a few passages, in gold. It is now in the university of Upsal.

ARGENTINA, in ichthyology, a genus of fishes belonging to the order of abdominales. The generic characters are these: the teeth are in the tongue, as well as the jaws; the branchiostege membrane has eight radii or rays; the anus is near the tail; and the belly fins consist of many rays. There are two species of argentina, *viz.*

1. Argentina carolina has likewise 15 rays in the fin near the anus; the tail is forked, and the lateral lines are straight. It inhabits the fresh waters of Carolina. See Plate X. Nat. Hist. fig. 38.

2. Argentina sphyræna has fifteen rays in the fin at the anus; the air bladder of this species is conical on both sides, and shines like silver: false pearls are sometimes made of it.

ARGENTUM *arborescens.* Most metallic substances are capable of decomposing a nitric solution of silver. The separation of this metal by mercury, on account of the phenomena which it presents, has been called the argentum arborescens, or more commonly the arbor Dianæ. It is obtained by the following process: mix together six parts of a solution of silver, and four of a solution of mercury, both made with nitric acid, and completely saturated; add to them a little distilled water, and put the mixture into a conical vessel, into which has been previously introduced six parts of an alloy made in the proportion of seven parts of mercury and one of silver. At the end of a few hours there will be formed, at the surface of the small mass of alloy, a vegetation in the form of a bush, as in Plate X. Nat. Hist. fig. 37. To obtain a beautiful specimen, it is necessary that all the ingredients be very pure: the glass best adapted to the purpose is conical or cylindrical.

ARGILLA, clay, in natural history. See Chymistry.

ARGO, in astronomy, a constellation of fixed stars in the southern hemisphere: the number of stars in Ptolemy's catalogue is 8, in Tycho's 11, and in Mr. Flamsteed's 25.

Argo, the vessel in which the Argonauts, of whom Jason was the chief, made an expedition in quest of the golden fleece.

ARGONAUTA, in conchology, the name of one of the Linnæan genera: animal a sepio or clio; shell univalve, spiral, involuted, membranaceous, and containing only one shell. There are two species, the most remarkable of which is the argonauta argo. See Plate X. Nat. Hist. fig. 30. The animal which is the inhabitant of this shell attracted the notice of the earliest writers on natural history. It is a native of the Mediterranean and Indian seas, and is supposed to have taught mankind the use of sails, and the art of navigation: it is the nautilus of English collectors. When this little creature intends to sail, it discharges a quantity of water, by which operation its specific gravity is rendered less than that of sea water; and rising to the surface, erects its arms, and expands a membrane between them, by means of which it is driven before the wind, like a vessel under sail; at the same time that two of its arms, which hang over the side of the shell, serve for oars and a rudder. In this manner it sports on the water in calm weather; but on the first indication of a storm, it lowers its sail, draws in its arms, takes in water, and sinks.

ARGOPHYLLUM, in botany, white leaf. A genus of the monogynia order, belonging to the pentandria class of plants. The capsule is trilocular; the nectarium is pyramidal, pentagonous, and the length of the corolla. There is but one species, *viz.*

Argophyllum nitidum, or the glossy argophyllum, a native of New Caledonia. This species has some affinity with the ivy.

ARGUMENT, argumentum, in rhetoric and logic, an inference drawn from premises, the truth of which is indisputable; or at least highly probable.

Argument, in astronomy, denotes a known arch, by means of which we seek another one unknown.

The argument of the moon's latitude is her distance from the node; and the argument of inclination is an arch of a planet's orbit, intercepted between the ascending node and the place of the planet from the sun, numbered according to the succession of the signs of the zodiac.

Argument of inclination, or argument of latitude, of any planet, is an arch of a planet's orbit, intercepted between the ascending node and the place of the planet from the sun, numbered according to the succession of the signs.

Argument, menstrual, of latitude, is the distance of the moon's true place from the sun's true place. By this is found the quantity of the real obscuration in eclipses, or how many digits are darkened in any place.

Argument, annual, of the moon's apogee, or simply, annual argument, is the distance of the sun's place from the place of the moon's apogee; that is, the arc of the ecliptic comprised between those two places.

ARGUS SHELL, a species of porcelain shell, beautifully variegated with spots resembling, in some measure, those in a peacock's tail.

ARGYTHAMNIA, in botany, a genus of the class and order monoecia tetandria; the essential character is, male cal. four leaved; cor. four petalled; fem. cal. five leaved, cor. none, styles dicchotomous, caps. nicoceous, solitary seeds. There is one shrubby species, a native of Jamaica.

ARIADNE, a beautiful statue of Parian marble, which was for nearly 300 years one of the chief ornaments of Belvidere, where it was placed by pope Julius II. It is now in the museum of Paris. Ariadne is represented sleeping on the rocks of Naxos, where she has been ungratefully left by Theseus.

ARIANS, in church history, a sect of ancient Christians who denied the three persons in the Holy Trinity to be of the same essence, and affirmed Christ to be a creature; that he was inferior to the Father as to his deity; that he was neither co-eternal, nor co-equal with him; also, that the Holy Ghost was not God, but a creature of the Son. In their doxologies, they ascribed glory to the Father in the Son, through the Holy Ghost.

The term Arian, in modern times, is applied to all who believe in the pre-existence of Christ, but who consider him as inferior and subordinate to the Father.

ARIDAS, a kind of taffety, manufactured in the East Indies, from a shining thread which is got from certain herbs, whence they are styled aridas of herbs.

ARIDED, a fixed star of the second magnitude, in the extremity of the swan's tail.

ARIDULLAM, in natural history, a kind of zarnich found in the East Indies.

ARIES, in zoology. See Ram.

Aries, or the Ram, in astronomy, one of the constellations of the northern hemisphere, and the first of the old

twelve signs of the zodiac, and marked ♈ in imitation of a ram's head. It gives name to a twelfth part of the ecliptic, which the sun enters commonly about the 20th of March. The stars of this constellation, in Ptolemy's catalogue, are 18; in Tycho Brahe's 21; in Helvetius's 27; and in Flamsteed's 66: but they are mostly very small, only one being of the 2d magnitude, two of the 3d magnitude, and all the rest smaller.

ARILLUS, in botany, the proper or exterior coat or covering of the seed, which drying, falls off spontaneously. All seeds have not this appendage.

ARISH, a Persian long measure, containing about 38 English inches.

ARISTA, among botanists, a long needle like beard, which stands out from the husk of a grain of corn, grass, &c.

ARISTEA, in botany, a genus of the triandria monogynia class and order. The essential character is, petals six, style declinate, stigma funnel shaped gaping, capsule inferior with many seeds. There is one species, a native of the Cape.

ARISTIDA, in botany, a genus of the class and order triandria digynia. The essential character is, calyx two valved, corolla one valved, with three terminal awns. There are six species, all of them natives of the East and West Indies.

ARISTOLOCHIA, birthwort, a genus of the hexandria order, belonging to the gynandria class of plants; and in the natural method ranking under the 11th order, sarmentaceæ. It has no calyx; the corolla consists of one entire petal; and the capsule, which is below the flower, has six cells. The species are twenty-one; but only the following merit description.

Aristolochia Indica, or contrayerva of Jamaica, is a native of that island, where its roots are used instead of the true contrayerva. It has long trailing branches, which climb upon the neighbouring plants, and sometimes rise to a considerable height. The flowers are produced in small clusters toward the upper part of the stalks, which are of a dark purple colour.

Aristolochia serpentaria is a native of Virginia and Carolina, whence the radix serpentaria, or snakeroot, so much used in medicine, is brought over. The leaves grow close to the ground on footstalks an inch long, of a singular shape, and of a dark purple colour. A round canulated capsule succeeds the flower. It is filled with seeds, which are ripe in May. When planted in gardens, in countries where they are natives, they increase so much in two years, that one can scarce grasp the stalk of a single one. This species is usually found in woods near the roots of great trees.

The usual price of the root, when dried, is 6d. per lb. both in Virginia and Carolina; and the negro slaves employ a great part of the time allowed them by their masters in search after it.

Another species is the *clematitis*, the root of which has an aromatic bitterness, which is by no means unpleasant. This root is deservedly esteemed as a remedy in the malignant fevers and epidemic diseases of warm climates. It is given in substance in doses of from ten to thirty grains, and in infusions, from one to two drams.

ARITHMETIC is the science of numbers, and teaches the art of computing by them.

At what time this science was introduced into the world cannot be easily determined. History fixes neither the author nor the time. The Greeks very early made use of the letters of the alphabet to represent their numbers. The 24 letters, taken according to their order, at first denoted the numbers 1, 2, 3, 4, 5, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 100, 200, 300, 400, 500, 600, 700, and 800; to which they added the three following, ϛ, ϟ, ϡ, to represent 6, 90, and 900.

The Romans followed a like method; and besides characters for each rank of classes, introduced others for five, fifty, and five hundred. Their method is still used for distinguishing the chapters of books, and some other purposes. Their numeral letters and values are the following:

I	V	X	L	C	D	M
One,	five,	ten,	fifty,	one hundred,	five hundred,	one thousand.

Any number may be represented by repeating and combining these according to the following rules.

1. When the same letter is repeated twice, or oftener, its value is represented as often. Thus II signifies two; XXX thirty, CC two hundred. 2. When a numeral letter is placed after one of greater value, their values are added: thus XI signifies eleven, LXV sixty-five, MDCXXVIII one thousand six hundred and twenty-eight. 3. When a numeral letter is placed before one of greater value, the value of the less is taken from that of the greater: thus IV signifies four, XL forty, XC ninety, CD four hundred.

Sometimes Iↀ is used instead of D for 500, and the value is increased ten times by annexing ↀ to the right hand.

Thus, Iↀ signifies 500
Iↀↀ - 5000
Iↀↀↀ - 50000
Also, Cↀ is used for 1000
CCↀↀ for 10000
CCCↀↀↀ for 100000

Sometimes thousands are represented by drawing a line over the top of the numeral, $\overline{V}$ being used for five thousand, $\overline{L}$ for fifty thousand, $\overline{CC}$ two hundred thousand.

About the year of Christ 200, a new kind of arithmetic, called sexagesimal, was invented probably by Ptolemy, to remedy the difficulties of the common method, especially with regard to fractions. Every unit was supposed to be divided into 60 parts, and each of these into 60 others, and so on. Thus from one to 59 were marked in the common way: then 60 was called a sexagesima prima, or first sexagesimal integer, and had one single dash over it; so 60 was expressed thus I′; and so on to 59 times 60, or 3540, which was thus expressed LIX′. He now proceeded to 60 times 60, which he called a sexagesima secunda, and was thus expressed I″, In like manner, twice 60 times 60, or 7200, was expressed by II″; and so on till he came to 60 times 3600, which was a third sexagesimal, and expressed thus I‴. If any number less than 60 was joined with these sexagesimals, it was added in its proper characters without any dash: thus I′XV represented 60 and 15, or 75; I′VXXV is four times 60 and 25, or 265; X″II′XV is ten times 3000, twice 60 and 15, or 36, 135, &c. Sexagesimal fractions were marked by putting the dash at the foot, or on the left hand of the letter: thus $I_{'}$ or $'I$; denoted $\frac{1}{60}$; $I_{''}$ or $''I$, $\frac{1}{3600}$, &c. So nearly did the inventor of this method approach the Arabic, or common mode of notation; instead of sexagesimal progression, it was required only to substitute decimal, to make the signs of numbers from 1 to 9 simple characters, and to introduce the 0, a character which signifies nothing of it-

self, but which serves to fill up places. Though the sexagesimal whole numbers were soon laid aside after the introduction of the Arabic notation, sexagesimal fractions continued till the invention of decimals, and are even still used in the subdivisions of circular arcs and angles.

The method of notation, which we now use, came into Europe from the Arabians, by the way of Spain. The Arabs, however, do not pretend to be the inventors of the characters, but acknowledge that they received them from the Indians. Some imagine that they were found out by the Greeks, which is not probable; as Maximus Planudes, who lived toward the close of the 13th century, is the first Greek who makes use of them: and Dr. Wallis is of opinion that these characters must have been used in England at least as long ago as the year 1050, if not in ordinary affairs, at least in mathematical ones, and in astronomical tables.

The oldest treatises extant upon the theory of arithmetic, are the seventh, eighth, and ninth books of Euclid's Elements, which treat of proportion and of prime and composite numbers. Nicomachus the Pythagorean, wrote a treatise on the theory of arithmetic, consisting chiefly of the distinctions and divisions of numbers into classes, as plain, solid, triangular, quadrangular, and the rest of the figurate numbers as they are called, numbers odd and even, &c. with some of the more general properties of the several kinds. His arithmetic was published at Paris in 1533. The next remarkable writer on this subject is Boethius, who is supposed to have copied most of his work from Nicomachus.

From this time no remarkable writer on arithmetic appeared till about the year 1200, when Jordanus of Namur wrote a treatise on this subject, which was published and demonstrated by Joannes Faber Stapulensis in the 15th century: and, as learning advanced in Europe, the number of writers on arithmetic increased. About the year 1464, Regiomontanus, in his triangular tables, divided the radius into 10,000 parts instead of 60,000; and thus tacitly expelled the sexagesimal arithmetic; which, however, still remains in the division of time. Ramus, in his arithmetic, written about the year 1550, and published by Lazarus Schonerus in 1586, uses decimal periods in carrying on the square and cube roots to fractions. The same had been done before by our countrymen Buckley and Record; but the first who published an express treatise on decimals was Simon Stevinius, about the year 1582. Dr. Wallis is the first who took much notice of circulating decimals, and the honour of inventing logarithms is unquestionably due to lord Napier, baron of Merchiston in Scotland, about the end of the 16th or beginning of the 17th century. Arithmetic has thus advanced to a degree of perfection which the ancients could never have imagined possible, much less hoped to attain; and it may now be reckoned one of those few sciences which is in its nature capable of little further improvement.

The following marks are used as abbreviations in arithmetic.

$=$ is the si gnof equality.

$+$ signifies Addition; thus $2 + 3 = 5$, is 2 added to 3 equal to 5.

$-$ signifies Subtraction; thus $5 - 2 = 3$, is 5 less 2 equal to 3.

$\times$ signifies Multiplication; $9 \times 5 = 45$, is 9 multiplied by 5 is equal to 45.

$\div$ signifies Division; $54 \div 9 = 6$, is 54 divided by 9 is equal to 6.

$\sqrt{\ }$ signifies the Square Root, $\sqrt{9}$ is the square root of 9, which is equal to 3.

NOTATION AND NUMERATION.

The first elements of arithmetic are acquired during our infancy: small numbers are most easily apprehended: a child soon understands what is meant by two, or three, or four, but has no distinct notion of twenty or thirty. Experience removes this difficulty, and enables us to form many units into a class, and several of these smaller classes into one of a higher kind, and thus to advance through as many ranks of classes as occasion requires. If a boy arrange an hundred stones in one row, he would be tired before he could reckon them; but if he place them in ten rows of ten stones each, he will reckon an hundred with ease; and if he collect ten such parcels, he will reckon a thousand.

There does not seem to be any number naturally adapted for constituting a class of the lowest, or any higher rank to the exclusion of others. However, as ten has been generally used for this purpose by most nations who have cultivated this science, it is probably the most convenient for general use. Other scales may be assumed: thus, if eight were the scale, 6 times 3 would be two classes and two units, and the number of 18 would then be represented by 22. If 12 were the scale, 5 times 9 would be three classes and nine units, and 45 would be represented by 39, &c. By not observing the same scale in the various kinds of monies, weights, and the like, much of the difficulty in the practice of arithmetic arises.

All numbers are represented by the ten following characters.

1	2	3	4	5	6	7	8	9	0
One,	two,	three,	four,	five,	six,	seven,	eight,	nine,	cypher.

The nine first are called significant figures or digits When placed singly, they denote the simple numbers sub joined to the characters. When several are placed together, the first or right hand figure only is to be taken for its simple value: the second signifies so many tens, the third so many hundreds, and the others so many higher classes, according to the order in which they stand. And the cypher in any place denotes the want of a number in that place: thus, 20 denotes two tens and no units or simple number.

The following table shows the names and divisions of the classes.

8.	4	3	7,	9	8	2.	5	6	4,	7	3	8.	9	7	2,	6	4	5
Trillions.																		
Hundred thousand of billions																		
Ten thousand of billions																		
Thousand billions																		
Hundred billions																		
Ten billions																		
Billions.																		
Hundred thousand of millions																		
Ten thousand of millions																		
Thousand millions																		
Hundred millions																		
Ten millions																		
Millions.																		
Hundred thousands																		
Ten thousands																		
Thousands																		
Hundreds																		
Tens																		
Units																		

The first six figures from the right hand are called the unit period, the next six the million period, after which the trillion, quadrillion, quintillion, sextillion, septillion, octillion, and nonillion periods, follow in their order.

The whole art of arithmetic is comprehended in two operations, Addition and Subtraction. But as methods have been invented for facilitating these operations, and distinguished by the names of Multiplication and Division; these four rules are the foundation of all arithmetical operations.

ADDITION.

Addition is that operation by which several numbers of the same denomination are collected into one total.

RULE. Write the numbers distinctly, units under units, tens under tens, and so on. Then reckon the amount of the right hand column. If it be under ten, mark it down. If it exceed ten, mark the units only, and carry the tens to the next place. In like manner, carry the tens of each column to the next, and mark down the full sum of the left hand column.

Example.
468632
767345
234672
142131
223164
389879
796543
3022366

The best method of proving the truth of sums in Addition, is to add up the lines in a contrary direction: thus, if I begin at the bottom of the lines, when the sum is done, I add the figures again together, beginning each line from the top; and if the total in both cases correspond, it may be supposed right.

COMPOUND ADDITION.

Compound Addition teaches to collect several numbers of different denominations into one total.

RULE. (1) Place the numbers so that those of the same denomination may stand directly under each other, and draw a line below them. (2) Add up the figures in the lowest denomination, and find how many ones of the next higher denomination are contained in their sum. (3) Write down the remainder, and carry the ones to the next denomination; with which proceed as before; and so on, through all the denominations to the highest, whose sum must be all written down; and this sum, together with the several remainders, is the total sum required.

The method of proof is the same as in simple addition.

l.	*s.*	*d.*	*l.*	*s.*	*d.*
34	15	$2\frac{1}{4}$	51	18	$9\frac{1}{4}$
27	12	$9\frac{3}{4}$	15	9	$11\frac{1}{2}$
30	9	$11\frac{1}{2}$	76	4	9
79	15	$4\frac{1}{4}$	59	19	$7\frac{1}{2}$
172	13	$3\frac{3}{4}$	203	13	$1\frac{1}{4}$

The reason of this rule is evident: for, in addition of money, as 1 in the pence is equal to 4 in the farthings; 1 in the shillings to 12 in the pence; and in the pounds to 20 in the shillings; carrying as directed is nothing more than providing a method of digesting the money arising from each column properly in the scale of denominations: and, this reasoning will hold good in the addition of numbers of any denomination whatsoever. Thus to take an example in Troy weight, where 24 grains make a pennyweight, 20 pennyweights one ounce, and 12 ounces a pound.

lb.	*oz.*	*dwts.*	*gr.*	*lb.*	*oz.*	*dwts.*	*gr.*
45	11	19	22	54	9	17	15
53	9	17	15	97	8	15	7
24	10	13	23	41	3	19	23
99	9	10	8	88	11	7	16
224	6	6	20	282	10	0	13

Hence it is evident, that for a person to be expert in compound addition requires only a knowledge of the several tables of weights and measures: if, for instance, I have to pay for the carriage of four packages, marked A, B, C, and D; A weighing 4 tons, 16cwt. 3qrs. B 1 ton, 14cwt. 2qrs. 24lb. C 12cwt. 3qrs. 25lb. and D 3 tons, 17cwt. 0qr. 26lb. to be able to ascertain the weight of the whole, it is necessary that I should know the Avoirdupoise Table, of which a part is, that 28lb. make 1 quarter of a hundred weight, 4 quarters 1 hundred weight, and 20 hundred 1 ton; then I proceed as follows:

Tons.	*cwt.*	*qr.*	*lb.*
4	16	3	0
1	14	2	24
0	12	3	25
3	17	0	26
11	1	2	19

And I now find that I have to pay for 11 tons, 1cwt. 2qr. 19lb.

SUBTRACTION.

Subtraction is the operation by which we take a less number from a greater, and find their difference. The greater is called the *minuend*, and the less the *subtrahend*.

If any figure of the subtrahend be greater than the corresponding figure of the minuend, and having found and marked the difference, we add one to the next place of the subtrahend. This is called borrowing ten, because adding one to the subtrahend produces the same effect as taking one from the minuend.

RULE. Subtract units from units, tens from tens, and so on. If any figure of the subtrahend be greater than the corresponding one of the minuend, borrow ten.

Example.		
Minuend	5173694	47386414
Subtrahend	2421453	23792352
Remainder	2752241	23594062

To prove subtraction, add the remainder and subtrahend together; if their sum be equal to the minuend, the sum is right.

Or subtract the remainder from the minuend. If the difference be equal to the subtrahend, the sum is right.

RULE for Compound Subtraction. "Place like denominations under like, and borrow, when necessary, according to the value of the higher place."

lb.	*oz.*	*dwts.*	*gr.*	*l.*	*s.*	*d.*
45	8	14	15	95	7	$6\frac{1}{2}$
29	8	17	17	59	16	$9\frac{3}{4}$
15	11	16	22	35	10	$8\frac{1}{2}$

The reason for borrowing is the same as in simple subtraction. Thus in subtracting pence, we add 12 pence when necessary to the minuend, and at the next step, we add one shilling to the subtrahend.

The learner should acquire the habit, when two numbers are marked down, of placing such a number under the less, that, when added together, the sum may be equal to the greater. The operation is the same as subtraction, though conceived in a different manner, and is useful in balancing accounts, and on other occasions in the concerns of life.

MULTIPLICATION.

Multiplication is a compendious mode of addition, and teaches to find the amount of any given number by repeating it any proposed number of times. Thus, 8 multiplied by 5, or 5 times 8, is 40. The given numbers, 8 and 5, are called factors; the first, 8, the multiplicand, the second, 5, the multiplier; and the amount, 20, the product.

Ex.] 76859 mult. by 4, or 76859 added 4 times.

4	76859
	76859
307436	76859
	307436

If the multiplier be 10, we annex a cypher to the multiplicand. If the multiplier be 100, we annex two cyphers; and so on. The reason is obvious, from the use of cyphers in notation.

Rule. Place the multiplier under the multiplicand, and multiply the latter successively by the significant figures of the former; placing the right hand figure of each product under the figure of the multiplier from which it arises; then add the product.

Ex.] (a)

7329	37846	93956
365	235	8704
36645	189230	375824
43974	113538	657692
21987	75692	751648
2675085	8893810	817793024

A number which cannot be produced by the multiplication of two others is called a prime number; as 3, 5, 7, 11.

A number which may be produced by the multiplication of two or more smaller ones, is called a composite number. For example, 27, which arises from the multiplication of 9 by 3; and these numbers, 9 and 3, are called the component parts of 27.

If the multiplier be a composite number, we may multiply successively by the component parts.

Ex.] 7638 by 45, or 5 times 9

45	7638
	9
38190	68742
30552	5
343710	343710

Because the second product is equal to five times the first, and the first is equal to nine times the multiplicand, it is obvious that the second product must be five times nine, or forty-five times as great as the multiplicand.

If the multiplier be 5, which is the half of 10, we may annex a cypher and divide by 2. If it be 25, which is the fourth part of 100, we may annex two cyphers, and divide by 4. Other contractions of the like kind will readily occur to the learner.

To multiply by 9, which is one less than 10, we may annex a cypher; and subtract the multiplicand from the number it composes. To multiply by 99,999, or any number of 9's, annex as many cyphers, and subtract the multiplicand. The reason is obvious; and a like rule may be found, though the unit place be different from 9.

Multiplication is proved by repeating the operation, using the multiplier for the multiplicand, and the multiplicand for the multiplier. Or it may be done by casting out the nines; that is, cast out the nines of the multiplier and multiplicand, and set down the remainders. Multiply the remainders together, and if the excess of nines in their product be equal to the excess of 9's in the total product, the work may be deemed right: thus, in Ex. (a) above, the excess of nines in the multiplicand is 3, and in the multiplier it is 5, and $3 \times 5 = 15$, or six above nine, which I find is the excess of nines in the total product. The best method of proving Multiplication is by Division; and if that be adopted, the two rules must be learned at the same time. Then the proof of each example in Multiplication becomes a sum in Division, and *vice versa*.

COMPOUND MULTIPLICATION.

Compound Multiplication teaches to find the amount of any given number of different denominations, by repeating it any proposed number of times.

Rule. (1) Place the multiplier under the lowest denomination of the multiplicand. (2) Multiply the number of the lowest denomination by the multiplier, and find how many ones of the next higher denomination are contained in the product. (3) Write down the excess, and carry the ones to the product of the next higher denomination, with which proceed as before; and so on, through all the denominations to the highest; whose product, together with the several excesses, taken as one number, will be the whole amount required.

Examples of Money.

9lb. of tobacco, at 4*s*. $8\frac{1}{2}d$. per lb.

4	$8\frac{1}{2}$
	9

2*l*. 2 $4\frac{1}{2}$ the answer.

The product of a number consisting of several parts, or denominations, by any simple number whatever, will evidently be expressed by taking the product of that simple number and each part by itself as so many distinct questions; thus, 25*l*. 12*s*. 6*d*. multiplied by 9, will be 225*l*. 108*s*. 54*d*. =, by taking the shillings from the pence, and the pounds from the shillings, and placing them in the shillings and pounds respectively, 230*l*. 12*s*. 6*d*. which is the same as the rule; and this will be true when the multiplicand is any compound number whatever.

Case I. If the multiplier exceed 12, multiply successively by its component parts, instead of the whole number at once, as in simple multiplication.

Ex.] 16cwt. of cheese, at 1*l*. 18*s*. 8*d*. per cwt.

1*l*.	18*s*.	8*d*.
		4
7	14	8
		4

30*l*. 18*s*. 8*d*. the answer.

Case II. If the multiplier cannot be produced by the multiplication of small numbers, find the nearest to it, either greater or less, which can be so produced; then, multiply by the component parts as before, and for the odd parts add or subtract according as is required.

Ex.] 17 ells of holland, at 7*s.* 3½*d.* per ell.

7*s.*	3½*d.*
	4
1 10	10
	4
6 3	4
7	3½

6*l.* 11*s.* 0½*d.* the answer.

DIVISION.

Division teaches to find how often one number is contained in another of the same denomination, and thereby performs the work of many subtractions.

The number to be divided is called the dividend.

The number you divide by is called the divisor.

The number of times the dividend contains the divisor is called the quotient.

If the dividend contains the divisor any number of times, and some part or parts over, those parts are called the remainder.

Rule. (1) On the right and left of the dividend draw a curved line, and write the divisor on the left hand, and the quotient as it arises on the right. (2) Find how many times the divisor may be had in as many figures of the dividend as are just necessary, and write the number in the quotient. (3) Multiply the divisor by the quotient figure, and set the product under that part of the dividend used. (4) Subtract the last found product from that part of the dividend under which it stands, and to the right hand of the remainder bring down the next figure of the dividend; which number divide as before; and so on, till the whole is finished.

When the divisor does not exceed 12, the whole computation may be performed without setting down any figures except the quotient.

Ex.] 7)35868(5124 or 7)35868

5124

When the divisor is a composite number, and one of the component parts also measures the dividend, we may divide successively by the component parts.

EXAMPLE I.	EXAMPLE II.
30114 by 63	975 by 105 = 5 × 7 × 3
9)30114	5)975
7)3346	3)195
Quotient 478	7)65
	Quotient 9⅔.

This method might be also used, although the component parts of the divisor do not measure the dividend; but the learner will not understand how to manage the remainder till he be acquainted with the doctrine of vulgar fractions.

When there are cyphers annexed to the divisor, cut them off, and cut off an equal number of figures from the dividend; annex these figures to the remainder.

Ex.] To divide 378643 by 5200.

52|00)3786|43(72$\frac{43}{52}\frac{43}{00}$.

364

146

104

4243

The reason will appear by performing the operation at large, and comparing the steps.

COMPOUND DIVISION.

Compound Division teaches to find how often one given number is contained in another of different denominations.

Rule. (1) Place the numbers as in simple division. (2) Begin at the left hand, and divide each denomination by the divisor, setting the quotients under their respective dividends. (3) But if there be a remainder, after dividing any of the denominations except the least, find how many of the next lower denomination it is equal to, and add it to the number, if any, which was in this denomination before; then divide the sum as usual, and so on till the whole is finished.

The method of proof is the same as in simple division.

Examples of money.

Divide 225*l.* 2*s.* 4*d.* by 2.

2)225*l.* 2*s.* 4*d.*

112*l.* 11*s.* 2*d.* the quotient.

Case I. If the divisor exceed 12, divide continually by its component parts, as in simple division.

Ex.] What is cheese per cwt. if 16 cwt. cost 30*l.* 18*s.* 8*d.*?

4)30*l.* 18*s.* 8*d.*

4)7*l.* 14*s.* 8*d.*

1*l.* 18*s.* 8*d.* the answer.

Case II. If the divisor cannot be produced by the multiplication of small numbers, divide by it after the manner of long division.

Ex. Divide 74*l.* 13*s.* 6*d.* by 17.

17)74*l.* 13*s.* 6*d.*(4*l.* 7*s.* 10*d.* the quotient.

68

6

133

119

14

12

174

170

4

REDUCTION.

Reduction teaches to bring numbers from one name or denomination to another, without changing their value.

RULE. All great names are brought into smaller ones by multiplying with so many of the next less as make one of the greater, adding to the product the parts of the less name, if the number to be reduced be a compound one; and all small names are brought into greater by dividing by as many of the less as make one of the greater.

EXAMPLES.

1. Reduce 255*l.* 6*s.* 9*d.* into pence.

20

5106
12

61281

Here it is evident that 61281 pence is equal to 255*l.* 6*s.* 9*d.*

2. How many pounds are there in 122562 pence?

12)122562

20)10213 — 6

Answer 510*l.* 13*s.* 6*d.*

THE RULE OF THREE DIRECT.

The Rule of Three Direct teaches, by having three numbers given, to find a fourth, that shall have the same proportion to the third as the second has to the first.

RULE. (1) State the question: that is, place the numbers so, that the first and third may be the terms of supposition and demand, and the second of the same kind with the answer required. (2) Bring the first and third numbers into the same denomination, and the second into the lowest name mentioned. (3) Multiply the second and third numbers together, and divide the product by the first, and the quotient will be the answer to the question, in the same denomination you left the second number in; which may be brought into any other denomination required.

The method of proof is by inverting the question.

Ex. If 12*lb.* of cheese cost 9*s.* 6*d.* what will 4 cheeses cost, each weighing 1*qr.* 6*lb*?

If 12*lb.* : 9*s.* 6*d.* :: 1*qr.* 5*lb.* × 4.

12 28

114 33
4

132
114

528
1452

12)15048

12)1254 pence

20)104 6

5*l.* 4*s.* 6*d.*

Note. This rule, on account of its great and extensive usefulness, is oftentimes called the Golden Rule of Proportion; for, on a proper application of it, and the preceding rules, the whole business of arithmetic, as well as every mathematical inquiry, depends. The rule itself is founded on this obvious principle, that the magnitude or quantity of any effect varies constantly in proportion to the varying part of the cause; thus, the quantity of goods bought is in proportion to the money laid out; the space gone over by an uniform motion is in proportion to the time, &c. As the idea annexed to the term proportion is easily conceived, it would be more perplexing than instructive to explain, in this place, what is meant by it, in a strict geometrical sense. It may be sufficient, therefore, to observe, that, independent of the precise meaning of that word, and its deducible properties, the truth of the rule, as applied to ordinary inquiries, may be made very evident, by attending only to principles already explained. It is shown in multiplication of money, that the price of one multiplied by the quantity is the price of the whole: and in division, that the price of the whole divided by the quantity is the price of one. Now, in all cases of valuing goods, &c. where one is the first term of the proportion, it is plain that the answer found by this rule will be the same as that found by multiplication of money: and where one is the last term of the proportion, it will be the same as that found by division of money. In like manner, if the first term be any number whatever, it is plain that the product of the second and third terms will be greater than the true answer required, by as much as the price in the second term exceeds the price of one, or as the first term exceeds an unit. Consequently this product divided by the first term will give the true answer required, and is the rule.

THE RULE OF THREE INVERSE.

The Rule of Three Inverse teaches by having three numbers given to find a fourth, that shall have the same proportion to the second as the first has to the third.

If more require more, or less require less, the question belongs to the rule of three direct.

But if more require less, or less require more, it belongs to the rule of three inverse.

RULE. (1) State and reduce the terms as in the rule of three direct. (2) Multiply the first and second terms together, and divide their product by the third, and the quotient is the answer to the question, in the same denomination you left the second number in.

The method of proof is by inverting the question.

Ex.] What quantity of shalloon, that is 3 quarters of a yard wide, will line $7\frac{1}{2}$ yards of cloth, that is $1\frac{1}{2}$ yard wide?

1yd. 2qrs. : 7yds. 2qrs. :: 3 qrs.

4 4

6 30
6

3)180

4)60

15 yards, the answer.

More requiring more, is when the third term is greater than the first, and requires the fourth term to be greater than the second.

And less requiring less, is when the third term is less than the first, and requires the fourth term to be less than the second.

In like manner, more requiring less, is when the third term is greater than the first, and requires the fourth term to be less than the second.

And less requiring more, is when the third term is less than the first, and requires the fourth term to be greater than the second.

The reason of this rule may be explained from the principles of compound multiplication and division, in the same manner as the direct rule. For example: If 6 men can do a piece of work in 10 days, in how many days will 12 men do it?

$$\text{As } 6 \text{ men} : 10 \text{ days} :: 12 \text{ men} : \frac{6 \times 10}{12} = 5 \text{ days},$$

the answer. And here the product of the first and second terms, *i.e.* 6 times 10, or 60, is evidently the time in which one man would perform the work: therefore twelve men will do it in one twelfth part of that time, or 5 days; and this reasoning is applicable to any instance whatever.

Note. Much of the difficulty, which presents itself to the young student, in ascertaining whether a question be direct or inverse, may be removed, by adopting the following rule; which has recently been introduced in some of our seminaries, and much used.

Rule. Of the three given numbers, set that which is of the same name or kind as the term required or answer, for the third term; then consider whether the answer will be greater or less than this third term; if *greater*, set the *less* of the two remaining numbers for the first term, and the other for the second; but if *less*, set the *greater* of those two numbers for the first term, and the other for the second, and multiply and divide as under direct proportion.

COMPOUND PROPORTION.

Compound Proportion teaches to resolve such questions as require two or more statings by simple proportion; and that whether they are direct or inverse.

Rule. (1) Let that term be put in the second place which is of the same denomination with the term sought. (2) Place the terms of supposition, one above another, in the first place; and the terms of demand, one above another, in the third place. (3) The first and third term of every row will be of one name, and must be reduced to the same denomination. (4) Examine every row separately: by saying, if the first term give the second, does the third require more or less? If it require more, mark the less extreme with a cross; but if less, mark the greater extreme. (5) Multiply all those numbers together which are marked for a divisor, and those which are not marked for a dividend, and the quotient will be the answer sought.

Note. When the same numbers are found in the divisor as in the dividend, they may be thrown out of both. Or any numbers may be divided by their greatest common divisor, and the quotients taken instead of them.

Ex.] If 16 horses can eat up 9 bushels of oats in 6 days, how many horses will eat up 24 bushels in 7 days at the same rate?

$$\begin{array}{c} +\ 9 \text{ bushels} : 16 \text{ horses} :: 24 \text{ bushels} \\ 6 \text{ days} : \text{——} :: 7 \text{ days} + \end{array}$$

$$\frac{6 \times 16 \times 24}{9 \times 7}, \text{ by contraction} = \frac{2 \times 16 \times 24}{3 \times 7}$$

$$= \frac{2 \times 16 \times 8}{1 \times 7} = \frac{256}{7} = 36\tfrac{4}{7} \text{ horses, the answer.}$$

The reason of this rule may be readily shown from the nature of direct and inverse proportion: for every row in this case is a particular stating in one of those rules; and therefore if all the separate dividends be collected together into one dividend, and all the divisors into one divisor, their quotient must be the answer sought. Thus in the example:

$$\text{As } 9 \text{ bush.} : 16 \text{ horses} :: 24 \text{ bush.} : \frac{24 \times 16}{9} \text{ by rule}$$

of three direct. As 6 days : $\frac{24 \times 16}{9}$ horses :: 7 days : $\frac{24 \times 16 \times 6}{9 \times 7}$ by rule of three inverse, which is the same as the rule.

PRACTICE.

Practice is a contraction of the rule of three direct, when the first term happens to be an unit, or one: and has its name from its daily use amongst merchants and tradesmen, being an easy and concise method of working most questions that occur in trade and business.

The method of proof is by the rule of three direct.

An aliquot part of any number, is such a part of it, as being taken a certain number of times does exactly make the number.

General Rule.

1. Suppose the price of the given quantity to be 1*l.* or 1*s.* as is most convenient; then will the quantity itself be the answer at the supposed price. 2. Divide the given price into aliquot parts, either of the supposed price, or of another, and the sum of the quotients belonging to each will be the true answer required.

Ex.] What is the value of 526 yards of cloth, at 3*s.* $10\frac{1}{4}d.$ per yard.

		526		Ans. at 1*l.*			
3*s.* 4*d.* is	$\frac{1}{6}$	87	13 4	ditto at	0	3	4
4*d.* is	$\frac{1}{10}$	8	15 4	ditto at	0	0	4
2*d.* is	$\frac{1}{2}$	4	7 8	ditto at	0	0	2
$\frac{1}{4}$ is	$\frac{1}{8}$	0	10 $11\frac{1}{2}$	ditto at	0	0	$0\frac{1}{4}$
		101	7 $3\frac{1}{2}$	ditto at	0	3	$10\frac{1}{4}$ the full price.

In the above example, it is plain that the quantity 526 is the answer at 1*l.* consequently, as 3*s.* 4*d.* is the $\frac{1}{6}$ of a pound, $\frac{1}{6}$ part of that quantity, or 87*l.* 13*s.* 4*d.* is the price of 3*s.* 4*d.* in like manner, as 4*d.* is the $\frac{1}{10}$ part of 3*s.* 4*d.* so $\frac{1}{10}$ of 87*l.* 13*s.* 4*d.* or 8*l.* 15*s.* 4*d.* is the answer at 4*d.* And by reasoning in this way 4*l.* 7*s.* 8*d.* will be shown to be the price at 2*d.* and 10*s.* $11\frac{1}{2}d.$ the price at $\frac{1}{4}$. Now as the sum of all these parts is equal to the whole price, 3*s.* $10\frac{1}{4}d.$ so the sum of the answers belonging to each price, will be the answer at the full price required. And the same will be true in any example whatever.

VULGAR FRACTIONS.

In order to understand the nature of Vulgar Fractions, we must suppose unity, or the number 1, divided into several equal parts. One or more of these parts is called a fraction, and is represented by placing one number in a smaller character above a line, and another under it: for example, a two fifth part is written thus, $\frac{2}{5}$. The number under the line, 5, shows how many parts unity is divided into, and is called the denominator. The number above the line, 2, shows how many of these parts are represented, and is called the numerator.

It follows from the manner of representing fractions, that when the numerator is increased, the value of the fraction becomes greater; but, when the denominator is increased, the value becomes less. Hence we may infer, that, if the numerator and denominator be both increased, or both diminished, in the same proportion, the value is not altered; and, therefore, if we multiply both by any number whatever, or divide them by any number which measures both, we shall obtain other fractions of equal value. Thus, every fraction may be expressed in a variety of forms, which have all the same signification.

A fraction annexed to an integer, or whole number, makes a mixed number. For example, five and two third parts, or $5\frac{2}{3}$. A fraction, whose numerator is greater than its denominator, is called an improper fraction. For example, seventeen third parts, or $\frac{17}{3}$. Fractions of this kind are greater than unity. Mixed numbers may be represented in the form of improper fractions, and improper fractions may be reduced to mixed numbers, and sometimes to integers. A whole number may be treated as a fraction by making its denominator unity.

"To reduce mixed numbers to improper fractions: multiply the integer by the denominator of the fraction, and to the product add the numerator. The sum is the numerator of the improper fraction sought, and is placed above the given denominator."

Examples. $7\frac{1}{4}$: $8\frac{3}{5}$: $9\frac{1}{2}$

4	5	2
29	43	19

The answers are $\frac{29}{4}$, $\frac{43}{5}$, and $\frac{19}{2}$.

Because one is equal to two halves, or three third parts, or four quarters, and every integer is equal to twice as many halves, or four times as many quarters, and so on: therefore, every integer may be expressed in the form of an improper fraction, having any assigned denominator. The numerator is obtained by multiplying the integer into the denominator. Hence the reason of the foregoing rule is evident. 5, reduced to an improper fraction, whose denominator is 3, makes $\frac{15}{3}$, and this added to $\frac{2}{3}$, amounts to $\frac{17}{3}$.

"To reduce improper fractions to whole or mixed numbers: divide the numerator by the denominator."

Examples. $\frac{57}{9}$: $\frac{84}{11}$: $\frac{91}{18}$

9)57	11)84	18)91($5\frac{1}{18}$
		90
$6\frac{3}{9}$	$7\frac{7}{11}$	
		1

The answers are $6\frac{3}{9}$, $7\frac{7}{11}$, and $5\frac{1}{18}$.

This problem is the converse of the former, and the reason may be illustrated in the same manner.

"To reduce fractions to lower terms: divide both numerator and denominator by any number which measures both, and place the quotients in the form of a fraction."

Examples. $\frac{84}{27}$: $\frac{256}{16}$: $\frac{270}{360}$.

The answers are $\frac{28}{9}$; 16; $\frac{3}{4}$; for both the numerator and denominator of the first fraction is divisible by 3; of the second by 16; and of the third by 90: but the answers are of precisely the same value as the original fractions.

To find the greatest common measure of two numbers: divide the greater by the less, and the divisor by the remainder continually, till nothing remain; the last divisor is the greatest common measure.

Ex. Required the greatest number which measures 475 and 589?

```
475)589(1
  475
  ---
114)475(4
  456
  ---
 19)114(6
  114
  ---
    0
```

Here divide 589 by 475, and the remainder is 114; then divide 475 by 114, and the remainder is 19; then 114 by 19, and there is no remainder: from which we infer than 19, the last divisor, is the greatest common measure.

To explain the reason of this we must observe, that any number which measures two others, will also measure their sum, and their difference, and will measure any multiple of either. In the foregoing example, any number which measures 589 and 475, will measure their difference 114, and will measure 456, which is a multiple of 114; and any number which measures 475, and 456 will also measure their difference 19. Consequently, no number greater than 19 can measure 589 and 475. Again, 19 will measure them both, for it measures 114, and therefore measures 456, which is a multiple of 114 and 475, which is just 19 more than 456: and, because it measures 475, and 114, it will measure their sum 589. To reduce $\frac{475}{589}$ to the lowest possible terms, we divide both numbers by 19, and it comes to $\frac{25}{31}$.

If there be no common measure greater than 1, the fraction is already in the lowest terms.

If the greatest common measure of 3 numbers be required, we find the greatest measure of the two first, and then the greatest measure of that number, and the third. If there be more numbers we proceed in the same manner.

"To reduce fractions to others of equal value that have the same denominator: 1st, multiply the numerator of each fraction by all the denominators except its own. The products are numerators to the respective fractions sought." 2d, "Multiply all the denominators into each other; the product is the common denominator."

Ex. $\frac{4}{5}$ and $\frac{7}{9}$ and $\frac{3}{8}$ = $\frac{288}{360}$ and $\frac{280}{360}$ and $\frac{135}{360}$.

$4 \times 9 \times 8 = 288$ first numerator.
$7 \times 5 \times 8 = 280$ second numerator.
$3 \times 5 \times 9 = 135$ third numerator.
$5 \times 9 \times 8 = 360$ common denominator.

Here we multiply 4, the numerator of the first fraction, by 9 and 8, the denominators of the two others; and the product 288 is the numerator of the fraction sought, equivalent to the first. The other numerators are found in like manner, and the common denominator, 360, is obtained by multiplying the given denominators 5, 9, 8, into

each other. In the course of the whole operation the numerators and denominators of each fraction are multiplied by the same numbers, and therefore their value is not altered.

ADDITION OF VULGAR FRACTIONS.

RULE. Reduce them, if necessary, to a common denominator; add the numerators, and place the sum above the denominator.

Ex. 1. $\frac{3}{5} + \frac{2}{9} = \frac{27}{45} + \frac{10}{45} = \frac{37}{45}$.

2. $\frac{5}{7} + \frac{8}{9} + \frac{9}{10} = \frac{450}{630} + \frac{560}{630} + \frac{567}{630} = \frac{1577}{630}$.

The numerators of fractions that have the same denominator signify like parts; and the reason for adding them is equally obvious, as that for adding shillings or any other inferior denomination.

SUBTRACTION OF VULGAR FRACTIONS.

RULE. "Reduce the fractions to a common denominator; subtract the numerator of the subtrahend from the numerator of the minuend, and place the remainder above the denominator."

Examples. Subtract $\frac{3}{7}$ from $\frac{11}{12}$, and $\frac{5}{11}$ from $\frac{3}{4}$.

$\frac{11}{12} - \frac{3}{7}$	$\frac{3}{4} - \frac{5}{11}$
$11 \times 7 = 77$	$3 \times 11 = 33$
$3 \times 12 = 36$	$5 \times 4 = 20$
41	13 rem.
$12 \times 7 = 84$	$4 \times 11 = 44$

The answers are $\frac{41}{84}$, and $\frac{13}{44}$.

To subtract a fraction from an integer: Subtract the numerator from the denominator, and place the remainder above the denominator; prefix to this the integer diminished by unity.

Ex. Subtract $\frac{3}{5}$ from 12. Remainder $11\frac{2}{5}$.

MULTIPLICATION OF VULGAR FRACTIONS.

RULE. "Multiply the numerators of the factors together for the numerator of the product, and the denominators together for the denominator of the product."

Ex. 1st. $\frac{2}{3} \times \frac{5}{7} = \frac{10}{21}$

$2 \times 5 = 10$ numerator

$3 \times 7 = 21$ denominator.

Ex. 2. $8\frac{2}{5} \times 7\frac{3}{4} = \frac{1302}{20} = 65\frac{2}{20}$

$8\frac{2}{5} = \frac{42}{5}$

$7\frac{3}{4} = \frac{31}{4}$

$42 \times 31 = 1302$

$5 \times 4 = 20$

To multiply $\frac{5}{7}$ by $\frac{2}{3}$ is the same as to find what two third parts of $\frac{5}{7}$ comes to; if one third part only had been required, it would have been obtained by multiplying the denominator 7 by 3, because the value of fractions is lessened when their denominators are increased; and this comes to $\frac{5}{21}$; and, because two thirds were required, we must double that fraction, which is done by multiplying the numerator by 2, and comes to $\frac{10}{21}$. Hence we infer that fractions of fractions, or compound fractions, such as $\frac{2}{7}$ of $\frac{3}{5}$, are reduced to simple ones by multiplication. The same method is followed when the compound fraction is expressed in three parts or more.

If a number be multiplied by any integer, its value is increased. If it be multiplied by 1, or taken one time, it undergoes no alteration. If it be multiplied by a proper fraction, or taken for one half, two thirds, or the like, its value is diminished, and the product is less than the number multiplied.

DIVISION OF VULGAR FRACTIONS.

RULE. (1) "Multiply the numerator of the dividend by the denominator of the divisor. The product is the numerator of the quotient." (2) "Multiply the denominator of the dividend by the numerator of the divisor. The product is the denominator of the quotient."

Ex. Divide $\frac{2}{5}$ by $\frac{7}{9}$. Quotient $\frac{18}{35}$.

$2 \times 9 = 18$

$5 \times 7 = 35$

To explain the reason of this operation; suppose it required to divide $\frac{2}{5}$ by 7, or to take one seventh part of $\frac{2}{5}$. This is obtained by multiplying the denominator by 7, for the value of fractions is diminished by increasing their denominators, and it comes to $\frac{2}{35}$. Again, because $\frac{7}{9}$ is nine times less than seven, the quotient of any number divided by $\frac{7}{9}$ will be nine times greater than the quotient of the same number divided by 7. Therefore we multiply $\frac{2}{35}$ by 9, and obtain $\frac{18}{35}$.

If the divisor and dividend have the same denominator it is sufficient to divide the numerators.

Ex. $\frac{12}{17}$ divided by $\frac{3}{17}$ quotes 4.

The quotient of any number divided by a proper fraction is greater than the dividend. It is obvious, that any integer contains more halves, more third parts, and the like, than it contains units; and, if an integer and fraction be divided alike, the quotients will have the same proportion to the numbers divided; but the value of an integer is increased when the divisor is a proper fraction; therefore the value of a fraction in the like case is increased also.

The foregoing rule may be extended to every case, by reducing integers and mixed numbers to the form of improper fractions.

DECIMAL FRACTIONS.

A decimal fraction is a fraction whose denominator is ten or some power of ten: but instead of writing down the denominator, a comma is placed before the number, to mark the fraction; and whatever number of figures follows the comma, the same is the index of the power of ten in the denominator, or there must be as many cyphers after unit in the denominator, as figures after the comma.

Thus 4,7 is 4 and $\frac{7}{10}$.

.47	signifies Forty-seven hundredth parts.
.047	Forty-seven thousandth parts.
.407	Four hund. and 7 thousandth parts.
4.07	Four, and seven hundredth parts.
4.007	Four, and seven thousandth parts.

To reduce vulgar fractions to decimal ones: "Annex a cypher to the numerator, and divide it by the denominator, annexing a cypher continually to the remainder."

EXAMPLES.

$\frac{12}{75}$ = .16	$\frac{5}{64}$ = .078125	$\frac{2}{3}$ = .666, &c.
75)120(16	64)500(078125	3)20(666
75	448	18
450	520	20
450	512	18
0	80	20
	64	18
	160	20
	128	
	320	
	320	

The reason of this operation will be evident, if we consider that the numerator of a vulgar fraction is understood to be divided by the denominator; and this division is actually performed when it is reduced to a decimal.

Some vulgar fractions may be reduced to decimals, and are called finite decimals. Others cannot be exactly reduced, because the division always leaves a remainder; but, by continuing the division, we shall perceive how the decimal may be extended to any length whatever. These are called infinite decimals.

Lower denominations may be considered as fractions of higher ones, and reduced to decimals accordingly.

The value of decimal places decreases like that of integers, ten of the lower place in either being equal to one of the next higher; and the same holds in passing from decimals to integers. Therefore, all the operations are performed in the same way with decimals, whether placed by themselves or annexed to integers, as with pure integers. The only peculiarity lies in the arrangement and pointing of the decimals.

In addition and subtraction, "Arrange units under units, tenth parts under tenth parts, and proceed as in integers."

Add	32.035	from	13.348
	136.374	take	9.2993
	160.63		
	12.3645		4.0487
	341.4035		

In multiplication, "Allow as many decimal places in the product as there are in both factors. If the product has not so many places, supply them by prefixing cyphers on the left hand."

Ex. 1st.	1.37	2d.	.1572
	1.3		.12
	1096		.018864
	137		
	2.466		

The reason of this rule may be explained, by observing that the value of the product depends on the value of the factors: and since each decimal place in either factor diminishes its value ten times, it must equally diminish the value of the product.

To multiply decimals by 10, move the decimal point one place to the right; to multiply by 100, 1000, or the like, move it as many places to the right as there are cyphers in the multiplier.

In division, "Point the quotient so that there may be an equal number of decimal places in the dividend as in the divisor and quotient together."

Ex. Divide 14 by .7854.

.7854)14.000000(17.82, &c.
7854
61460
54978
64820
62832
19880

Therefore, if there be the same number of decimal places in the divisor and dividend, there will be none in the quotient.

Ex. Divide .75 by .25. Answer 3, which is a whole number.

If there be more in the dividend, the quotient will have as many as the dividend has more than the divisor. See above.

If there be more in the divisor, we must annex, or suppose annexed, as many cyphers to the dividend as may complete the number of decimals in the divisor, and all the figures of the quotient are integers.

Ex. Divide 8 by .125.

.125)8.000(64 Answer in whole numbers.
7.50
500
500
0

To reduce numbers of different denominations to their equivalent decimal values: Rule. (1) Write the given numbers perpendicularly under each other, beginning at the least. (2) Opposite each dividend, on the left hand, place such a number for a divisor as will bring it to the next superior name, and draw a perpendicular line between them. (3) Begin with the highest; and write the quotient of each division, as decimal parts, on the right hand of the dividend next below it, and so proceed to the last; and the last quotient is the decimal sought.

Ex. Reduce 15*s.* 9½*d.* to the decimal of a *l.*

4	3.
12	9.75
20	15.8125

.790625 the decimal required.

To find the value of any given decimal in terms of the integer. Rule. Multiply the decimal by the number of parts in the next less denomination, and cut off as many places for a remainder, to the right hand, as there are places in the given decimal; and so proceed with the rest.

Ex. What is the value of .375 of a *l.*

.375
20

s. 7.500
12

d. 6.000 Answer 7*s.* 6*d.*

If the divisor leave a remainder, the quotient may be extended to more decimal places; but those are not regarded in fixing the decimal point. See above.

The reason for fixing the decimal point as directed, may be inferred from the rule followed in multiplication. The quotient multiplied by the divisor produces the dividend; and therefore the number of decimal places in the dividend is equal to those in the divisor and quotient together.

Some decimals, though extended to any length, are never complete; and others, which terminate at last, sometimes consist of so many places, that it would be difficult in practice to extend them fully. In these cases, we may extend the decimal to three, four, or more places, according to the nature of the articles, and the degree of accuracy required. In this manner we may perform any operation with ease by the common rules, and the answers we obtain are sufficiently exact for any purpose in business.

ON THE EXTRACTING OF ROOTS.

The root is a number, whose continual multiplication into itself produces the power; and is denominated the square, cube, 4th, 5th, root, &c. according as it is, when raised to the 2d, 3d, 4th, 5th, &c. power, equal to that power. Thus 2 is the square root of 4, because $2 \times 2 = 4$; and 4 is the cube root of 64, because $4 \times 4 \times 4 = 64$; and so on.

Although there is no number of which we cannot find any power exactly, yet there may be many numbers of which a precise root can never be determined. But, by the help of decimals, we can approximate toward the root, to any assigned degree of exactness.

The roots which approximate are called surd roots, and those which are perfectly accurate are called rational roots.

Roots are sometimes denoted, as in algebra, by writing the character $\surd$ before the power, with the index of the root against it: thus, the third root of 70 is expressed $\sqrt[3]{70}$, and the second root of it is $\surd 70$, the index 2 being always omitted when the square or second root is designed.

If the power be expressed by several numbers, with the sign + or — between them, a line is drawn from the top of the sign over all the parts of it; thus, the third root of 28 — 13 is $\sqrt[3]{28-13}$.

Sometimes roots are designed like powers, with fractional indices; thus, the square root of 5 is $5^{\frac{1}{2}}$, the third root of 19 is $19^{\frac{1}{3}}$, and the fourth root of 40 — 12 is $\overline{40-12}^{\frac{1}{4}}$, &c.

TO EXTRACT THE SQUARE ROOT.

Rule. (1) Distinguish the given number into periods of two figures each, by putting a point over the place of units, another over the place of hundreds, and so on. (2) Find a square number either equal to, or the next less than, the first period; and put the root of it to the right hand of the given number, after the manner of a quotient figure in division, and it will be the first figure of the root required. (3) Subtract the assumed square from the first period, and to the remainder bring down the next period for a dividend. (4) Place the double of the root already found, on the left hand of the dividend, for a divisor. (5) Consider what figure must be annexed to the divisor, so that if the result be multiplied by it, the product may be equal to, or the next less than, the dividend, and it will be the 3d figure of the root. (6) Subtract the product from the dividend, and to the remainder bring down the next period, for a new dividend. (7) Find a divisor as before, by doubling the figures already in the root; and from these find the next figures of the root, as in the last article; and so on through all the periods to the last.

Note. If there are decimals in the given number, it must be pointed both ways from unity, and the root be made to consist of as many whole numbers and decimals as there are periods belonging to each; and when the figures belonging to the given number are exhausted, the operation may be continued at pleasure by adding cyphers.

EXAMPLES.

Required the square root of 5499025.

5499025 (2345 the root.
4

43)149
129

464)2090
1856

4685)23425
23425

0

EXTRACTION OF THE CUBE ROOT.

Rule. (1) Find by trial the nearest rational cube to the given number, and call it the *assumed* cube. (2) Then, as twice the assumed cube added to the given number, is to twice the given number added to the supposed cube, so is the root of the supposed cube to the root required nearly. (3) By taking the cube of the root thus found for the supposed cube, and repeating the operation, the root may be had to a still greater degree of exactness.

Ex. 1. What is the cube root of 12484?

By trial I find the nearest root, less than the given number, is 23, the cube of which is 12167.

Then $12167 \times 2 + 12484 = 36818$, and
$12484 \times 2 + 12167 = 37135$. Therefore as 36818 : 37135 :: 23 : 23.198, and 23.198 is the root required nearly.

2. What is the cube root of 2?

As the nearest rational root is 1, we have $1 \times 2 + 2 = 4$, and $2 \times 2 + 1 = 5$.

Then $4 : 5 :: 1 : \frac{5}{4} = 1.25 =$ root nearly.

Again, the cube of $\frac{5}{4} = \frac{125}{64}$, therefore $\frac{125}{64} \times 2 + 2 : 2 \times 2 + \frac{125}{64} :: \frac{5}{4}$, or $\frac{378}{64} : \frac{381}{64} :: \frac{5}{4} : \frac{635}{504} = 1.2599$, &c.

TO EXTRACT THE ROOTS OF POWERS IN GENERAL.

Rule 1. Prepare the given number for extraction, by pointing off from the units place as the root required directs.

2. Find the first figure of the root by trial, and subtract its power from the given number.

3. To the remainder bring down the first figure in the next period, and call it the dividend.

4. Involve the root to the next inferior power to that which is given, and multiply it by the number denoting the given power for a divisor.

5. Find how many times the divisor may be had in the dividend, and the quotient will be another figure of the root.

6. Involve the whole root to the given power, and subtract it from the given number as before.

7. Bring down the first figure of the next period to the remainder for a new dividend, to which find a new divisor, and so on till the whole is finished.

Ex. What is the cube root of 53157376

$$\dot{5}3\dot{1}57\dot{3}76(376$$
$$27 = 3^3$$

$3^2 \times 3 = 27)261$ dividend.

$$50653 = 37^3$$

$3^2 \times 3 = 4107)25043$ second dividend.

$$53157376$$

$$0$$

The reason of the process in the Extraction of Roots may be seen in Algebra.

Thus we have gone over all the principal rules in common arithmetic, giving under each an example or examples, by the assistance of which the reader may invent any number of others for his own improvement in the branch of science. We have not touched upon simple interest, discount, loss and gain, &c. because these are but modifications of the Rule of Three; and may be done either by the rules there given, or by Practice. We doubt not that this article, if followed by that under the word Algebra, which though first in order in a dictionary necessarily comes last in practice, will be found sufficient for almost all purposes in common life.

Arithmetic, decimal, that containing the doctrine of decimal fractions. See Arithmetic.

Arithmetic of infinites, the doctrine of infinite series. See Series.

Arithmetic, instrumental, that performed by means of instruments, as the abacus or counting board, Napier's bones, &c.

Arithmetic, literal, the same with specious. See Algebra.

Arithmetic, logarithmetical, that performed by means of logarithms. See Logarithm.

Arithmetic, logistical, the same with sexagesimal.

Arithmetic, sexagesimal, the doctrine of sexagesimal fractions.

Arithmetic, specious, the same with algebra. See Algebra.

ARITHMETICAL, *complement of a logarithm*, the sum or number which a logarithm wants of 10,000000: thus the arithmetical complement of the logarithm 8.154032 is 1.845968.

Arithmetical *progression*. See Algebra.

Arithmetical *proportion*. See Algebra.

ARITHMOMANCY, a species of divination performed by means of numbers.

ARLEQUIN, an English trivial name applied to some birds, insects, shells, &c. remarkable for their striking colours.

ARM, in respect of the magnet. A loadstone is said to be armed when it is enclosed, capped, or set in iron or steel, in order to increase its magnetic virtue.

Arm, in sea language. A ship is said to be armed when fitted out and provided in all respects for war.

ARMADILLO. See Dysapus.

ARMED, in the sea language. A cross bar shot is said to be armed when some ropeyarn or the like is rolled about the end of the iron bar which runs through the shot.

Armed, in heraldry, is used when the horns, feet, beak, or talons, of any beast or bird of prey, are of a different colour from the rest of their body. He bears a cock or a falcon armed, &c.

ARMENIANS, in church history, a sect or division amongst the eastern Christians; thus called from Armenia, the country anciently inhabited by them. There are two kinds of Armenians; the one catholic, and subject to the pope, having a patriarch in Persia and another in Poland; the other makes a peculiar sect, having two patriarchs in Natolia. They are generally accused of being monophysites, only allowing of one nature in Jesus Christ. As to the eucharist, they, for the most part, agree with the Greeks; they abstain rigorously from eating of blood, and meats strangled, and are much addicted to fasting.

ARMENTA. See Bos.

ARMIGER, an esquire, or armour bearer.

ARMILLA *membranosa*, in anatomy, is that circular ligament which comprehends all the tendons belonging to the whole hand within a circle, in the region of the carpus.

ARMILLARY, Armillaris, in a general sense, something consisting of rings, or circles, from *armilla*, a bracelet.

Armillary *sphere*, an artificial sphere, composed of a number of circles, representing the several circles of the mundane sphere, put together in their natural order, to ease and assist the imagination in conceiving the constitution of the heavens, and the motions of the celestial bodies.

The armillary sphere turns upon its axis P *p*, Plate XIV. Miscel. fig. 4. within a silvered horizon H O, which is divided into degrees, and moveable every way, upon a brass supporter. E Q represents the equinoctial, and A B the zodiac, which is a broad circle divided into degrees, and into twelve equal parts, marked with the twelve signs ♈, ♉, ♊, &c. P Q *p* E, is the meridian, likewise divided into degrees.

The other parts are the two tropics, and two polar circles, both delineated in the figure.

ARMINIANS, in church history, a sect of Christians, which arose in Holland, by a separation from the Calvin-

ists. They are great asserters of free will. They speak very ambignously of the prescience of God. They look on the doctrine of the Trinity as a point not necessary to salvation; and many of them hold there is no precept in Scripture by which we are enjoined to adore the Holy Ghost; and that Jesus is not equal to God the Father.

ARMOISIN, a silk stuff, or kind of taffety, manufactured in the East Indies, at Lyons in France, and Lucca in Italy. That of the Indies is slighter than those made in Europe.

ARMONIAC. See AMMONIA.

ARMONICA. See HARMONICA.

ARMORIAL. See HERALDRY.

ARMOUR denotes all such habiliments as serve to defend the body from wounds, especially of darts, a sword, a lance, &c. A complete suit of armour formerly consisted of a helmet, a shield, a cuirasse, a coat of mail, a gauntlet, &c. all now laid aside.

ARMS, *charged*, in heraldry, are such as retain their ancient integrity, with the addition of some new honourable bearing.

ARMS, *canting* or *vocal*, those in which there are some figures, alluding to the name of the family.

ARMS, *full* or *entire*, such as retain their primitive purity, without any alterations or abatements.

ARMS, *false*, such as are not conformable to the rules of heraldry.

ARMS, in falconry, the legs of a hawk from the thigh to the foot.

ARMS, *king at*, } see HERALD.
ARMS, *herald at*, }

ARMS, *poursuivant at*, see POURSUIVANT.

ARMS, *college of*, see COLLEGE *of arms*.

ARMY. An army is composed of squadrons and battalions, and is usually divided into three corps, and formed into three lines; the first line is called the van guard, the second the centre or main body, and the third the rear guard, or body of reserve. The middle of each line is possessed by the foot; the cavalry forms the right and left wing of each line; and sometimes they place squadrons of horse in the intervals between the battalions. When the army is drawn up in order of battle, the horse are placed at five feet distance from each other, and the foot at three. In each line the battalions are distant from each other 180 feet, which is nearly equal to the extent of their front; and the same holds of the squadrons, which are about 300 feet distant, the extent of their own front. These intervals are left for the squadrons and battalions of the second line to range themselves against the intervals of the first, that both may more readily march through those spaces to the enemy: the first line is usually 300 feet distant from the second, and the second from the third, that there may be sufficient room to rally, when the squadrons and battalions are broken.

An army sometimes acquires different appellations from the particular services in which it is employed. A *covering* army is that which covers a place, by lying encamped for the protection of the different passes which lead to the principal object of defence. An army is said to *blockade* a place when, being well provided with heavy artillery, &c. it is employed to invest a town for the purpose of reducing it by assault or famine. An army of *observation* is so called because, by its advanced positions and desultory movements, it is constantly employed in watching the enemy. Such is a body of troops engaged by besiegers to prevent relief being brought into a place, or the seige being raised by the enemy. An army of *reserve* is a sort of general *depot* for effective service. In cases of emergency, the whole, or part of an army of reserve, is employed to recover a lost day, or to secure a victory. A *flying* army is a strong body of horse and foot, usually commanded by a lieutenant general, which is always in motion, to cover its own garrisons, or to keep the enemy in perpetual alarm.

ARNICA, *leopard's bane*, in botany, a genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the forty ninth order, compositæ discoides. The receptacle is naked; the pappus is simple; and the filaments are five, without antheræ. There are twelve species, five of which are European, and have been used in medicine as discutients in chronic rheumatism, lumbago, &c. also internally in intermittents.

ARNOLDISTS, in church history, sectaries so called from their leader Arnold of Bresia, who was a great declaimer against the wealth and vices of the clergy; and who is also charged with preaching against baptism and the eucharist.

AROLEC, an American weight, equal to twenty-five of our pounds.

AROMA, or the odorant principle of plants, is distinctly characteristic in each individual. Water impregnated with this principle, is termed the distilled water of the plant; of these a great variety is used in pharmacy.

AROMATICS, in pharmacy, substances that possess a fragrant penetrating smell, a strong pungent taste, and a considerable stimulating power on the system in general. See MATERIA MEDICA.

AROURA, a Grecian measure of fifty feet. It was more frequently used for a square measure of half the plethron. The Egyptian aroura was the square of one hundred cubits.

ARPENT, a term sometimes used to denote an acre.

ARRACHE'E, in heraldry, a term applied to the representations of plants torn up by the roots.

ARRACK, or RACK, a spirituous liquor imported from the East Indies, used by way of dram and in punch. The word arrack, according to Mr. Lockyer, is an Indian name for strong waters of all kinds; for they call our spirits and brandy English arrack. But what we understand by the name arrack, he affirms is properly no other than a spirit procured by distillation from a vegetable juice called toddy, which flows by incisions out of the cocoa nut tree, like the birch juice procured among us. The toddy is a pleasant drink by itself, when new, but purges those who are not used to it; when stale, it is heady, and makes good vinegar. The English at Madras use it as leaven to raise their bread with.

There are, however, several kinds of arrack, distinguished by different names; such as Batavia arrack, a vinous spirit obtained by distillation from rice and sugar fermented with the juice of cocoa nuts. It is a strong spirit; but being made in copper stills, is not so agreeable as Goa arrack. Bitter, black, and Columbo arrack, are hot spirits little valued, and seldom imported by Europeans.

The manner of making the Goa arrack is this: The juice of the trees is not procured in the way of tapping, as we

do; but the operator provides himself with a parcel of earthen pots, with bellies and necks like our bird bottles; he makes fast a number of these to his girdle, and any way else that he commodiously can about him. Thus equipped, he climbs up the trunk of a cocoa tree; and when he comes to the boughs, he takes out his knife, and cutting off one of the small knots or buttons, he applies the mouth of the bottle to the wound, fastening it to the bough with a bandage; in the same manner he cuts off other buttons, and fastens on his pots, till the whole number is employed: this done in the evening, descending from the tree, he leaves them till the next morning; when he takes off the bottles, which are mostly filled, and empties the juice into the proper receptacle. This is repeated every night, till a sufficient quantity is produced; and the whole being then put together, is left to ferment, which it soon does. When the fermentation is over, and the liquor or wash is become a little tart, it is put into the still, and a fire being made, the still is suffered to work as long as that which comes over has any considerable taste of spirit. The liquor thus procured is the low wine of arrack; and this is so poor a liquor, that it will soon corrupt and spoil, if not distilled again, to separate some of its watery parts; they therefore immediately after pour back this low wine into the still, and rectify it to that very weak kind of proof spirit, in which state we find it. The arrack we meet with, notwithstanding its being a proof test, according to the way of judging by the crown of bubbles, holds but a sixth, and sometimes but an eighth, part of pure spirit; whereas our other spirits, when they show that proof, are generally esteemed to be one half pure spirit. There is a paper of observations on arrack, in the Melanges d'Histoire Natur. tom. v. p. 302. By fermenting, distilling, and rectifying the juice of the American maple, which has much the same taste as that of the cocoa, the author says he made arrack not in the least inferior to any that comes from the East Indies; and he thinks the juice of the sycamore and of the birch trees would equally answer the end.

Arrack is not to be sold in Great Britain but in warehouses entered as directed by 6th of Geo. I. cap. 21. upon forfeiture, and casks, &c.

ARRACK, *tungusian*, is a spirituous liquor made by the Tartars of Tungusia, of mare's milk, left to sour, and afterward distilled twice or thrice between two earthen pots closely stopped, whence the liquor runs through a small wooden pipe. It is more intoxicating than brandy.

ARRAGONITE. See MINERALOGY.

ARRAIGNMENT, in law, the arraigning or setting a thing in order; as a person is said to arraign a writ of novel disseisin, who prepares and fits it for trial. It is most properly used to call a person to answer in form of law upon an indictment, &c. at the suit of the king.

ARRAY, in law, the ranking or setting forth of a jury or inquest of men empannelled on a cause.

ARRENTATION, in the forest law, is the licensing an owner of lands in a forest, to enclose them with a low hedge, and a small ditch, in consideration of a yearly rent.

ARREST, the apprehending and restraining a person, in order to oblige him to be obedient to the law; which in all cases, except treason, felony, or breach of the peace, must be done by virtue of a precept out of some court. Outer doors may be broken open to arrest a felon; but in civil cases it is otherwise, unless it is in pursuit of one before taken.

Attornies, &c. maliciously causing any person to be arrested, shall forfeit ten pounds and treble damages. The same penalty is incurred for arresting a person, except in criminal cases, and an escape warrant, on Sundays; but arrests made in the night are equally lawful with those by day.

Peers of the realm, and members of parliament, may not be arrested for debt; nor can any other subject be arrested for less than 10*l.* on a procees issued out of a superior court, or 40*s.* in an inferior one.

ARREST *of judgment*, the assigning just reasons why judgment should not pass; as want of notice of the trial, a material defect in the pleading, when the record differs from the deed pleaded, when persons are misnamed, when more is given by the verdict than is laid in the declaration, &c. This may be done either in criminal or civil cases.

ARRESTANDIS *bonis*, &c. a writ that lies for one whose cattle or goods are taken by another, who is likely to carry them away before the contest is decided.

ARRESTO *facto super bonis*, &c. a writ brought by a denizen against the goods of aliens found within this kingdom, as a recompense for goods taken from him in a foreign country.

ARRHABONARII, a sect of Christians who held that the eucharist is neither the real flesh nor blood of Christ, nor yet the sign of them, but only the pledge or earnest of them.

ARRHEPHORIA, a feast among the Athenians, instituted in honour of Minerva, and Herse daughter of Cecrops.

ARROBA, a weight used in Spain, in Portugal, at Goa, and throughout all Spanish America. The arroba of Portugal is 32 Lisbon lbs. of Spain 25 Spanish lbs.

ARRONDE'E, in heraldry, a cross, the arms of which are composed of sections of a circle: not opposite to each other, so as to make the arms bulge out thicker in one part than another; but the sections of each arm lying the same way, so that the arm is every where of an equal thickness, and all of them terminating at the edge of the escutcheon like the plain cross.

ARROW, in surveying, small sticks shod with iron, to stick into the ground at the end of the chain.

ARROW, in astronomy. See SAGITTA.

ARSCHIN, in commerce, a long measure used in China to measure stuffs. Four arschins make three yards of London.

ARSENIC, one of the semimetals, in a combined state, or in the state of an ore, extremely fatal as a poison, whence its name: composed of ανηρ, a man, and νικαω, to kill. It is commonly seen in the state of a calx, oxide, or ore, the natural colour of which is white.

The white oxide of arsenic, or what is known in commerce by the name of arsenic, is mentioned by Avicenna in the eleventh century; but at what period the metal called arsenic was first extracted from that oxide is unknown. It was only in the year 1733 that this metal was examined with chymical precision. This examination, which was performed by Mr. Brandt, demonstrated its peculiar nature; and since that time it has always been considered as a distinct metal, to which the term *arsenic* has been appropriated.

Arsenic has a bluish white colour not unlike that of steel, and a good deal of brilliancy. It has no sensible smell while cold, but when heated it emits a strong odour of gar-

lic, which is very characteristic. Its specific gravity is 8.31. It is perhaps the most brittle of all the metals, falling to pieces under a very moderate blow of a hammer, and admitting of being easily reduced to a very fine powder in a mortar. Its fusing point is not known, because it is the most volatile of the metals, subliming without melting when exposed in close vessels to a heat of 540°. When sublimed slowly, it crystalizes in tetrahedrons, which Hauy has demonstrated to be the form of its integrant particles. It may be kept under water without alteration; but when exposed to the open air, it soon loses its lustre, becomes black, and falls into powder.

Arsenic is capable of combining with two doses of oxygen, and of forming compounds. When exposed to a moderate heat, in contact with air, it sublimes in the form of a white powder, and at the same time emits a smell resembling garlic. If the heat is increased, it burns with an obscure bluish flame. Arsenic, indeed, is one of the most combustible of the metals. The substance which sublimes was formerly called *arsenic* or *white arsenic*, and is still known by these names in the commercial world. It is a combination of arsenic and oxygen; and is now denominated *white oxide of arsenic*, and by Fourcroy *arsenious acid*, because it possesses several of the properties of an acid. It is seldom prepared by chymists, because it exists native; and is often procured abundantly during the extraction of the other metals from their ores. When obtained by these processes, it is a white, brittle, compact substance, of a glassy appearance. It has a sharp, acrid taste, which at last leaves an impression of sweetness, and is one of the most virulent poisons known. It has an alliaceous smell. It is soluble in 80 parts of water at the temperature of 60 degrees, and in 15 parts of boiling water. This solution has an acrid taste, and reddens vegetable blues. When it is slowly evaporated, the oxide crystalizes in regular tetrahedrons. This oxide sublimes when heated to 383 degrees: if heat is applied in close vessels, it becomes pellucid like glass; but when exposed to the air, it soon recovers its former appearance. The specific gravity of this glass is 3.000; that of the oxide, in its usual state, 3.706. This oxide is capable of combining with most of the metals, and in general renders them brittle. From the experiments of Proust it appears, that this oxide is composed of . . . 75.2 arsenic.

24.8 oxygen.

100.0

Arsenic is capable of combining with an additional dose of oxygen, and of forming another compound, first discovered by Scheele, known by the name of arsenic acid. The process prescribed by Scheele is, to dissolve three parts of white oxide of arsenic in seven parts of muriatic acid, to add five parts of nitric acid, to put the mixture into a retort, and distill to dryness. The dry mass is to be merely brought to a red heat, and then cooled again. It is solid arsenic acid.

Arsenic does not combine with carbon nor hydrogen. This last substance, however, when in the gaseous state, dissolves it; for when muriatic acid is boiled over arsenic, that metal is gradually oxidized and dissolved, and at the same time hydrogen gas is emitted, which has the smell and the poisonous qualities of arsenic. Sulphur combines readily with arsenic. If we put a mixture of these two bodies into a covered crucible and melt them, a red vitreous mass is obtained, which is obviously a sulphuret of arsenic. It may be formed also by heating together the white oxide of arsenic, or arsenic acid and sulphur. But in that case a portion of the sulphur absorbs the oxygen from the arsenic, and makes its escape in the form of sulphureous acid gas. If the white oxide of arsenic is dissolved in muriatic acid, and a solution of sulphureted hydrogen in water is poured into the liquid, a fine yellow coloured powder falls to the bottom. This powder is usually called orpiment. It may be formed by subliming arsenic and sulphur by a heat not sufficient to melt them. This substance is also found native. It is composed of thin plates which have a considerable degree of flexibility. Its specific gravity is 3.415.

Arsenic combines readily with phosphorus. The phosphuret of arsenic may be formed by distilling equal parts of its ingredients over a moderate fire. It is black and brilliant, and ought to be preserved in water. It may be formed likewise by putting equal parts of phosphorus and arsenic into a sufficient quantity of water, and keeping the mixture moderately hot for some time.

Arsenic does not combine with azotic gas nor muriatic acid; neither is it readily oxidized by the action of that acid; but it unites with most metals, and in general renders them more brittle and fusible. Melted gold takes up 1-60th of arsenic. The alloy is brittle and pale, and much harder than gold. The alloy of platina and arsenic is brittle and very fusible. The arsenic may be separated by heat. It is by fusing platina and the white oxide of arsenic together that this untractable metal is formed into the utensils required. The mixture, after fusing, is hammered at a red heat into bars. The arsenic is gradually driven off, and carries along with it most of the baser metals which happen to be present. The platina is then sufficiently ductile to be wrought. Melted silver takes up 1-14th of arsenic. The alloy is brittle, yellow coloured, and useless. Mercury may be amalgamated with arsenic by keeping them for some hours over the fire, constantly agitating the mixture. The amalgam is gray coloured, and composed of five parts of mercury, and one of arsenic. Copper may be combined with arsenic by fusing them together in a close crucible; while their surface is covered with common salt to prevent the action of the air, which would oxidize the arsenic. This alloy is white and brittle, and is used for a variety of purposes; but it is usual to add to it a little tin or bismuth. It is known by the names of white copper and white tombac. When the quantity of arsenic is small, the alloy is both ductile and malleable. Iron and arsenic may be alloyed by fusion. The alloy is white and brittle, and may be crystalized. It is found native; and is known among mineralogists by the name of mispickel. Iron is capable of combining with more than its own weight of arsenic. Tin and arsenic may be alloyed by fusion. The alloy is white, harder, and more sonorous than tin; and brittle, unless the proportion of arsenic is very small. An alloy, composed of 15 parts of tin, and one of arsenic, crystalizes in large plates like bismuth; it is more brittle than zinc, and more infusible than tin. The arsenic may be separated by long exposure of the alloy to heat in the open air. Lead and arsenic may be combined by fusion. The alloy is brittle, dark coloured, and composed of

plates. Lead takes up 1-6th of its weight of arsenic. Nickel combines readily with arsenic, and indeed is seldom found without being more or less contaminated by that metal. The compound has a shade of red, considerable hardness, and a specific gravity considerably under the mean. It is not magnetic. Arsenic possesses the curious property of destroying the magnetic virtue of iron, and all other metals susceptible of that virtue. Zinc may be combined with arsenic by distilling a mixture of it and of white oxide of arsenic. This alloy, according to Bergmann, is composed of four parts of zinc and one of arsenic. Antimony forms with arsenic an alloy which is very brittle, very hard, and very fusible; and composed, according to Bergmann, of seven parts of antimony and one part of arsenic. Bismuth may be combined with about 1-15th of its weight of arsenic; but the properties of this alloy have not been examined.

The affinities of arsenic, and of its oxides, are placed by Bergmann in the following order:

Arsenic.	*Oxide of arsenic.*
Nickel,	Muriatic acid,
Cobalt,	Oxalic,
Copper,	Sulphuric,
Iron,	Nitric,
Silver,	Tartaric,
Tin,	Phosphoric,
Gold,	Fluoric,
Platina,	Saclactic,
Zinc,	Succinic,
Antimony,	Citric,
Sulphur,	Lactic,
Phosphorus.	Arsenic,
	Acetic,
	Prussic.

ARSIS and THESIS, in music. A point is said to move *per arsin et thesin*, which rises in one part and falls in another, and *vice versa*.

ARSON, in law, the same with houseburning, which is felony at common law, and likewise by statute.

ART and PART, in the law of Scotland, is applied to an accomplice.

ARTEDIA, a genus of the digynia order, belonging to the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The involucra are pinnatifid; the floscules of the disc are masculine; and the fruit is hispid with scales. There is but one species.

ARTEL, a name given to a commercial association, consisting of a certain number of labourers, who voluntarily become responsible as a body for the honesty of each individual. The separate earnings of each man are put into a common stock; a monthly allowance is made for his support; and at the end of the year the surplus is equally divided. Hence arises the denomination of *artelschisks*, persons employed by the Russian merchants of St. Petersburg to collect debts, &c. These are mostly natives of Archangel of the lowest class, yet their fidelity is rarely to be complained of.

ARTEMISIA, *mugwort*, *southernwood*, and *wormwood*, a genus of the polygamia superflua order, belonging to the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ nucamentaceæ. The receptacle is either naked or a little downy; it has no pappus; the calyx is imbricated with roundish scales; and the corolla has no radii. There are 44 species, of which the following are the most remarkable, *viz.*

1. Artemisia abrotanum, or southernwood, which is kept in gardens for the sake of its agreeable scent, is a low shrub, seldom rising more than three or four feet high, sending out lateral shrubby branches, growing erect, garnished with five bristly leaves, having a strong scent when bruised.

2. Artemisia absinthium, or common wormwood, grows naturally in lanes and uncultivated places, and is too well known to require any particular description.

3. Artemisia arborescens, or tree wormwood, grows naturally in Italy and the Levant, near the sea. It rises, with a woody stalk, six or seven feet high, sending out many ligneous branches, with leaves somewhat like those of the common wormwood, but more finely divided, and much whiter.

4. Artemisia dracunculus, or tarragon, is frequently used in sallads, especially by the French, and is a very hardy plant, spreading greatly by its creeping roots.

5. Artemisia maritima, or sea wormwood, grows naturally on the seacoasts in most parts of Britain, where there are several varieties, if not distinct species to be found.

6. Artemisia Pontica, or Pontic wormwood, commonly called Roman wormwood, is a low herbaceous plant, whose stalks die in autumn, and new ones appear in the spring. They are garnished with finely divided leaves, whose under sides are woolly; and the upper part of the stalks are furnished with globular flowers which nod on one side, having naked receptacles.

7. Artemisia santonicum produces the semen santonicum, which is much used for worms in children. It grows naturally in Persia, whence the seeds are brought to Europe. It has the appearance of our wild mugwort.

8. Artemisia vulgaris, or common mugwort, grows naturally on banks and by the sides of foot paths in many parts of Britain. Most of these are easily propagated by slips or cuttings.

ARTERIOSE *canal*, a tube in the heart of a fœtus, that, with the foramen ovale, is of use to preserve the circulation of the blood, &c.

ARTERIOTOMY, the opening an artery with design to procure an evacuation of blood.

This operation is used only in extraordinary cases, as it is very dangerous; and must be practised in the temples, the forehead, or behind the ears, where the arteries are easily closed again.

ARTERY, in anatomy, a conical tube or canal which conveys the blood from the heart to all parts of the body. See ANATOMY.

ARTHRITIS, gout. See MEDICINE.

ARTHRODIA, in natural history, a genus of imperfect crystals, found always in complex masses; and forming long single pyramids, with very short and slender columns.

ARTHRODIA, a species of articulation, wherein a flat head of one bone is received into a shallow socket of another.

ARTICHOAK. See CINARA.

ARTICHOAK, *Jerusalem*, a species of sunflower. See HELIANTHUS.

ARTICLE, in grammar, a particle in most languages that serves to express the several cases and genders of

nouns, when the languages have not different terminations to denote the different states and circumstances of nouns.

The Latin has no article; but the Greeks have their ὁ: the eastern languages have their *he emphaticum;* and most of the modern languages have had recourse to articles. The only articles made use of in the English tongue, are *a* and *the;* which, prefixed to substantives, determine their general signification to some particular thing. The use of *a* is in a general sense, and may be applied to any particular person or thing, and upon that account is called an *indefinite article;* but *the*, being a determinate article, is called definite or demonstrative, as applying the word to one individual. The French have three articles, *le, la*, and *les;* the Italians have their *il, lo*, and *la;* and the Germans their *der, das*, and *dat*.

ARTICLES *of war*, are known regulations for the government of the army in the united kingdom, dominions beyond the seas, and foreign parts dependent upon this country. They may be altered at the pleasure of the sovereign; and in certain cases they extend to civilians: as when by proclamation any place shall be put under martial law, or when the people follow a camp or army for the sale of merchandize, or serve in any menial capacity. It is ordained that the articles of war shall be read in the circle of each regiment belonging to the British army every month, or oftener if thought proper. A soldier is not liable to be tried by a military tribunal unless the articles of war have been read to him.

ARTICULATE *sounds* are such sounds as express the letters, syllables, or words, of any alphabet or language: such are formed by the human voice, and by some few birds, as parrots, &c. Other brutes cannot articulate the sounds of their voice.

ARTICULATION, in anatomy, denotes the juncture of two bones intended for motion.

Articulation is of two kinds: the first is called diarthrosis, being that which has a manifest motion: that which only admits of an obscure motion is called synarthrosis. The former is subdivided into enarthrosis, arthrodia, and ginglymus. The latter is subdivided into symphysis, syntenosis, sutura, harmonia, syssarcosis, synchondrosia, and synneurosis. See ANATOMY.

ARTICULATION, in botany, jointed as the culm or stalk of reeds, corn, &c. It is also said of pods, like those of the hedyrarum or French honeysuckle, which when ripe divide into so many parts or joints.

ARTIFICER, a person whose employment it is to manufacture any kind of commodity, as in iron, brass, wool, &c. such are smiths, weavers, carpenters, &c. If any such conspire not to work under certain prices, they are liable to divers penalties. Persons that contract with artificers in wool or metals to go out of the kingdom shall be fined in any sum not exceeding 100*l.* and imprisoned for three months. If artificers that are abroad do not return in six months after warning, they shall be deemed aliens, and be incapable of inheriting lands by descent.

By several acts passed during the present reign, heavy penalties are inflicted on masters of ships assisting to seduce artificers to leave these realms.

ARTIFICER, in a military sense, he who prepares bombs, grenades, &c.

ARTIFICIAL *lines*, on a sector or other scale, are certain lines, contrived to represent the logarithmic sines and tangents; which, by the help of a line of numbers, will solve questions in trigonometry, navigation, &c.

ARTILLERY signifies all sorts of great guns or cannon, mortars, howitzers, petards, and the like; together with all the apparatus and stores thereto belonging, which are not only taken into the field, but likewise to sieges, and made use of both to attack and defend fortified places. It signifies also the science of artillery or gunnery.

ARTILLERY, *train of*, consists in an unlimited number of pieces of ordnance; such as 24 pounders, 18 pounders, 12, 9, 6, and 3 pounders; mortars from 13 to 8 inches diameter; besides royals and cohorns; howitzers of every denomination, mounted on their proper carriages and beds, &c. There is moreover attached to the train a sufficient quantity of horses, spare carriages, spare mortar beds, &c.

The train of artillery is, or should be, divided into brigades, to which belong not only the officers of the regiments of artillery, but even the civil list, such as comptrollers, commissaries of stores, clerks of stores, &c. The increase of artillery clearly demonstrates its great utility; for in the year 1500, an army of 50,000 men had only 40 pieces of cannon in the field; and in the year 1757, the same number of troops brought 200 pieces into the field, including mortars and howitzers.

At the battle of Jemappe, which was fought between the French and Austrians on the 6th of November, 1792, the latter had 120 pieces of cannon disposed along the heights of Framery, whilst their effective force in men did not exceed 17,000. The French on this occasion brought nearly the same quantity of ordnance, some indeed of extraordinary calibre, but their strength in men was considerably more formidable.

ARTILLERY, *brigade of*, generally consists of 8 or 10 pieces of cannon, with all the machinery and officers to conduct them, and all the necessary apparatus thereto belonging.

ARTILLERY, *park of*, is that place appointed by the general of an army to encamp the train of artillery, apparatus, ammunition, as well as the battalions of the artillery, appointed for its service and defence. The figure of the park of artillery is that of a parallelogram, unless the situation of the ground renders another necessary.

The park of artillery is generally placed in the centre of the second line of encampment, and sometimes in the rear line, or corps of reserve. In both places the muzzles of the guns are in a line with the fronts of the serjeants' tents of the regiments of artillery and infantry. Some generals choose to place the park about 300 paces before the centre of the front line of the army. But let the situation be where it will, the manner of forming the park is almost every where the same. The most approved method is to divide the whole into brigades, placing the guns of the first to the right of the front line, and their ammunition behind them in one or more lines. The different brigades should be all numbered, as well as every waggon belonging to them. This method will prevent confusion in the forming and breaking up of the park, as also on a march: besides, according to the numbers, the stores therein contained are known.

ARTILLERY, *field*, includes every requisite to forward the operations of an army, or of any part of an army acting offensively or defensively in the field. Field artillery

may be divided into two distinct classes: field artillery properly so called, and horse artillery.

Regiments of artillery are always encamped half on the right and half on the left of the park. The company of bombardiers, when they are formed into companies, always takes the right of the whole, and the lieutenant colonel's company the left; next to the bombardiers, the colonels, the majors, &c. so that the two youngest are next but one to the centre or park: the two persons next to the park are the miners on the right, and the artificers on the left.

The colours are placed in the centre of the front line of guns, in the interval of the two alarm guns, in a line with the bells of arms of the companies.

The lieutenant colonel's and major's tents front the centres of the second streets from the right and left of the regiment.

ARTILLERY, *march of.* The marches of the artillery are, of all the operations of war, the most delicate, because they must not only be directed on the object in view, but according to the movements the enemy make. Armies generally march in three columns, the centre column of which is the artillery: should the army march in more columns, the artillery and heavy baggage march nevertheless in one or more of the centre columns: the situation of the enemy determines this. If they are far from the enemy, the baggage and ammunition go before or behind, or are sent by a particular road; an army in such a case cannot march in too many columns. But should the march be toward the enemy, the baggage must be all in the rear, and the whole artillery form the centre column, except some brigades, one of which marches at the head of each column, with guns loaded, and burning matches, preceded by a detachment for their safety. The French almost invariably place their baggage in the centre.

A detachment of pioneers, with tools, must always march at the head of the artillery, and of each column of equipage or baggage.

If the enemy is encamped on the right flanks of the march, the artillery, &c. should march to the left of the troops, and *vice versa.* Should the enemy appear in motion, the troops front that way, by wheeling to the right or left by divisions; and the artillery which marches in a line with the columns, passes through their intervals, and forms at the head of the front line, which is formed of the column that flanked nearest the enemy, taking care at the same time that the baggage be well covered during the action.

ARTILLERY *company*, a regular battalion of infantry under the command of officers who are annually elected. It consists of gentlemen of character and property, bound by solemn declaration and obligation of attachment and fidelity to the king and constitution, and of readiness to join in supporting the civil authority, and of defending the metropolis. See the History of this Company, by A. Highmore, Esq.

ARTOCARPUS, from αρτος, bread, and καρπος, fruit, the BREAD FRUIT TREE, a genus of the monandria order, belonging to the monoecia class of plants. It has a cylindric amentum or catkin, which thickens gradually and is covered with flowers: the male and female in a different amentum. In the male the calyx is two valved, and the corolla is wanting. In the female, there is no calyx or corolla: the stylus is one, and the drupa is many celled. There are two species, *viz.*

1. Artocarpus incisa. Though this tree has been mentioned by many voyagers, particularly by Dampier, by Rumphius, and by lord Anson, yet very little notice seems to have been taken of it, till the return of captain Wallis from the South Seas.

Captain Cook, in his Voyage, observes, that this fruit not only serves as a substitute for bread among the inhabitants of Otaheite, and the neighbouring islands, but also, variously dressed, composes the principal part of their food. It grows on a tree that is about the size of a middling oak; its leaves are frequently a foot and a half long, of an oblong shape, deeply sinuated like those of the fig tree, which they resemble in colour and consistence, and in the exuding of a milky juice upon being broken. The fruit is about the size and shape of a new born child's head, and the surface is reticulated, not much unlike a truffle; it is covered with a thin skin, and has a core about as big as the handle of a small knife. The eatable part lies between the skin and the core; it is as white as snow, and somewhat of the consistence of new bread: it must be roasted before it is eaten, being first divided into three or four parts; its taste is insipid, with a slight sweetness, somewhat resembling that of the crumb of wheaten bread mixed with a Jerusalem artichoak. This fruit is also cooked in a kind of oven, which renders it soft, and something like a boiled potato; not quite so farinaceous as a good one, but more so than those of the middling sort. Of the bread fruit they also make three dishes, by putting either water or the milk of the cocoa nut to it, then beating it to a paste with a stone pestle, and afterward mixing it with ripe plantains, bananas, or the sour paste which they call mahie.

The unripe artocarpus mahie, is likewise made to serve as a succedaneum for ripe bread fruit before the season is come on. The fruit of the bread tree is gathered just before it is perfectly ripe; and being laid in heaps, is closely covered with leaves: in this state it undergoes a fermentation, and becomes disagreeably sweet; the core is then taken out entire, which is done by gently pulling out the stalk, and the rest of the fruit is thrown into a hole which is dug for that purpose generally in the houses, and neatly lined on the bottom and side with grass: the whole is then covered with leaves, and heavy stones laid upon them; in this state it undergoes a second fermentation, and becomes sour, after which it will suffer no change for many months. It is taken out of the hole as it is wanted for use; and being made into balls, it is wrapped up in leaves and baked: after it is dressed, it will keep for five or six weeks. It is eaten both cold and hot; and the natives seldom make a meal without it, though to Europeans the taste is as disagreeable as that of a pickled olive generally is the first time it is eaten.

To procure this principal article of their food, costs these happy people no trouble or labour, except climbing up a tree: the tree which produces it does not indeed grow spontaneously; but if a man plants ten of them in his life time, which he may do in an hour, he will as completely fulfil his duty to his own and future generations, as the native of our less temperate climate can do, by ploughing in the cold of winter, and reaping in the summer's heat, as often as these seasons return: even if after

he has procured bread for his present household, he should convert a surplus into money, and lay it up for his children.

2. Artocarpus integrifolia, with entire leaves. This is called in the East Indies the joccahee. It bears fruit like the other, but it seems to be of an inferior kind. It is said there are above 30 varieties of this tree.

ARTOTYRITES, in church history, a sect of Christians who used bread and cheese in the eucharist, or bread, perhaps, baked with cheese; urging, in defence of this practice, that in the first ages of the world, men offered to God the fruits of their flocks, as well as those of the earth.

ARTS are commonly divided into liberal and mechanical: the former comprehending poetry, painting, sculpture, architecture, &c. and the latter, the whole body of mechanical trades, as carpentry, masonry, turnery, &c.

Arts, *fine*, a term synonymous with the French expression beaux arts, and perhaps imitated from it. The fine arts are painting, sculpture, architecture, engraving, drawing, and music; formerly classed under the more general and appropriate description of the liberal arts. See Painting, Sculpture, &c.

ARVALES fratres, in Roman antiquity, a college of twelve priests, instituted by Romulus.

ARUM, wakerobin, or cuckow pint, in botany, a genus of the polyandria order, belonging to the gynandria class of plants, and in the natural method ranking under the 2d order, piperitæ. The spatha is monophyllous, and cowl shaped: the spadix is naked above, female below, and stamineous in the middle. There are 32 species, of which the most remarkable are the following:

1. Arum arborescens, or dumb cane, is a native of the sugar islands and warm parts of America, where it grows chiefly on low grounds. All the parts of it abound with an acrid juice, so that if a leaf or part of the stalk is broken and applied to the tip of the tongue, it occasions a very painful sensation and a great defluxion of saliva. The stalks of this plant are sometimes applied to the mouths of the negroes by way of punishment.

2. Arum arisarium, as well as the arum proboscidium and arum tenuifolium, are all distinguished by the general name of friar's cowl, on account of the resemblance of their flowers to the shape of the cowls worn by friars. The flowers appear in April.

3. Arum colocasia, as well as the arum divaricatum, esculentum, peregrinum, and sagittifolium, have all mild roots, which are eaten by the inhabitants of the hot countries, where they grow naturally. Even the leaves of some of them, particularly those of the esculentum, which they call Indian kale, in those countries where many of the esculent vegetables of England are with difficulty produced, prove a good succedaneum.

4. Arum divaricatum has spear shaped leaves.

5. Arum dracunculus, or the common dragons, grows naturally in most of the southern parts of Europe. It has a straight stalk, three or four feet high, which is spotted like the belly of a snake: at the top it is spread out into leaves, which are cut into several narrow segments almost to the bottom, and are spread open like a hand; at the top of the stalk the flower is produced, which is in shape like the common arum, having a long spathe of a dark purple colour, standing erect, with a large pistil of the same colour.

6. Arum Italicum is a native of Italy, Spain, and Portugal. The leaves rise a foot and a half high, terminating in a point; they are very large, and finely veined with white, interspersed with black spots, which, together with the fine shining green, make a pretty variety.

7. Arum maculatum, or common wakerobin, grows naturally in woods and on shady banks in most parts of Britain. The leaves are halberd shaped, very entire and spotted; the berries numerous, growing in a naked cluster. The flowers appear in April; and their wonderful structure has given rise to many disputes among the botanists. The receptacle is long, in the shape of a club, with the seed buds surrounding its base. The chives are fixed to the receptacle amongst the seed buds, so that there is no occasion for the tips to be supported upon threads, and therefore they have none; but they are fixed to the fruit stalk, and placed between two rows of tendrils: the point in dispute is, what is the use of those tendrils?

8. Arum trilobatum, or arum of Ceylon, is a native of that island and some other parts of India, and cannot bear cold. It is a low plant; the flower rises immediately from the root, standing on a very short footstalk: the spatha is long, erect, and of a fine scarlet colour, as is also the pistil.

The roots of the maculatum and dracunculus are used in medicine, and differ in nothing but that the latter is somewhat stronger than the former. This root is a powerful stimulant and attenuant. It is reckoned a medicine of efficacy in some cachectic and chlorotic cases, and in weakness of the stomach. Great benefit has been obtained from it in rheumatic pains, particularly those of the fixed kind, and which were seated deep. In these cases it may be given from 10 grains to a scruple of the fresh root twice or thrice a day, made into a bolus or emulsion with unctuous and mucilaginous substances.

ARUNDELIAN marbles, called also the Parian Chronicle, are ancient stones, on which is inscribed a chronicle of the city of Athens, supposed to have been engraven in capital letters, in the island of Paros, 264 years before Christ. They take their name from the earl of Arundel, who procured them from the East, or from his grandson, who presented them to the university of Oxford. The authenticity of these marbles has led to a controversy between Mr. Robertson, who in his 'Parian Chronicle' questioned it, and Mr. Hewlett, who defended it in a 'Vindication of the Authenticity of the Parian Chronicle,' which see.

ARUNDO, in botany, the reed, a genus of the digynia order, belonging to the triandria class of plants, and in the natural method ranking under the fourth order, gramina. The calyx consists of two valves, and the floscules are thick and downy. There are 14 species; the most remarkable are:

1. Arundo bambos, or the bamboo, a native of the East Indies and some parts of America; where it frequently attains the height of 60 feet. The main root is long, thick, jointed, spreads horizontally, and sends out many cylindrical woody fibres, of a whitish colour, and many feet long. From the joints of the main root spring several

round jointed stalks to a prodigious height, and at about 10 or 12 feet from the ground send out at their joints several stalks joined together at their base: these run up in the same manner as those they shoot out from. If any of these is planted with a piece of the first stalk adhering to them, they will perpetuate their species. They are armed at their joints with one or two sharp rigid spines, and furnished with oblong oval leaves, eight or nine inches long, seated on short footstalks. The flowers resemble those of the common reed. The young shoots are covered with a dark green bark; these when very tender are put in vinegar, salt, garlic, and the pods of capsicum, and thus afford a pickle which is esteemed a valuable condiment in the Indies, and is said greatly to promote the appetite and assist digestion. The stalks in their young state are almost solid, and contain a milky juice: this is of a sweet nature; and as the stalks advance in age they become hollow except at the joints, where they are stopped by a woody membrane, upon which this liquor lodges, and concretes into a substance called tabaxir, or sugar of Mombu; which was held in such esteem by the ancients in some particular disorders, that it was equal in value to its weight in silver. The old stalks grow to five or six inches diameter, and are then of a shining yellow colour: and are so hard and durable that they are used in buildings, and for making all sorts of household furniture; and when bored through the membranes at their joints, are converted into water pipes. The smaller stalks are used for walking sticks, and the inhabitants of Otaheite make flutes of them about a foot long, with two holes only; which they stop with the first finger of the left hand and the middle one of the right, and then blow through their nostrils.

2. Arundo donax, or cultivated reed, is a native of warm countries, but will bear the cold of our moderate winters in the open air. The stalks of this are brought from Spain and Portugal, and are used by the weavers, as also for making fishing rods.

3. Arundo orientalis is what the Turks use as writing pens; it grows in a valley near mount Athos, as also on the banks of the river Jordan.

4. Arundo phragmitis, or the common marsh reed, grows by the sides of our rivers, and in standing waters.

The arundo versicolor, or Indian variegated reed, is supposed to be a variety of the donax, differing from it only in having variegated leaves; and the arundo picta, or striped grass, is a variety of the Canary grass.

ARUSPICES, or HARUSPICES, an order of priesthood among the Romans, that pretended to foretell future events by inspecting the entrails of victims killed in sacrifice.

ARYTÆNOIDES, in anatomy, the name of two cartilages, which, together with others, constitute the head of the larynx. It is also applied to some muscles of the larynx.

AS, in antiquity, a particular weight, consisting of twelve ounces, being the same with libra, or the Roman pound.

As was also the name of a Roman coin, which was of different matter and weight, according to the different ages of the commonwealth.

It is also used to signify an integer divisible into twelve parts, from which last acceptation it signified a whole inheritance.

The as had several divisions; the principal of which were the uncia, or ounce, being the twelfth part of the as; sextans, the sixth part of the as; quadrans, the fourth part; triens, the third part; and semis, half the as, or six ounces. Bis was two thirds of the as, or eight ounces; and dodrans, three fourths of the as.

ASA, in the materia medica, a name given to two very different vegetable productions, distinguished by epithets expressive of their smell.

Asafœtida is a very stinking gum, drawn, according to Kempfer, from the root of an umbelliferous plant, which grows in the province of Chorasan in Persia.

ASAPPES, or AZAPES, in the Turkish armies, a name given to the auxiliary troops which they raise among the Christians under their dominion, and expose to the first shock of the enemy.

ASARUM, ASARABACCA, a genus of the monogynia order, belonging to the dodecandria class of plants. The calyx is trifid or quadrifid, and rests on the germen; there is no corolla; the capsule is leathery and crowned. There are three species, *viz.*

1. Asarum Canadense, a native of Canada.

2. Asarum Europæum, grows naturally in some parts of England.

3. Asarum Virginicum, a native of America, has no remarkable properties.

The principal use of this plant among us is as a sternutatory. The root of asarum is perhaps the strongest of all the vegetable errhines, white hellebore itself not excepted. Snuffed up the nose, in the quantity of a grain or two, it occasions a large evacuation of mucus, and raises a plentiful spitting. The leaves are considerably milder, and may be used to the quantity of 3, 4, or 5 grains. Geoffery relates, that after snuffing up a dose of this errhine at night, he has frequently observed the discharge from the nose to continue for 3 days together, and that he has known a paralysis of the mouth and tongue cured by one dose.

ASBESTUS, in mineralogy. This mineral was well known to the ancients. They even made a kind of cloth from one of the varieties, which was famous among them for its incombustibility. It is found abundantly in most mountainous countries, and no where more abundantly than in Scotland.

It is found in amorphous masses. Its texture is fibrous. Its fragments often long, splintery. Specific gravity from 2.995 to 0.6806. Absorbs water. Colour usually white or green. Fusible per se by the blowpipe.

1st. Common asbestus. Specific gravity 2.547 to 2.995. Feels somewhat greasy. Colour leek green; sometimes olive or mountain green; sometimes greenish or yellowish gray. Streak gray. Powder gray.

Flexible asbestus. Amianthus. Composed of a bundle of threads slightly cohering. Fibres flexible. Specific gravity, before it absorbs water, from 0.9088 to 2.3134; after absorbing water, from 1.5662 to 2.3803. Feels greasy. Colour grayish or greenish white; sometimes yellowish or silvery white, olive or mountain green.

Elastic asbestus. Mountain cork. This variety has a strong resemblance to common cork. Its fibres are interwoven. Specific gravity, before absorbing water, from 0.6806 to 0.9933; after absorbing water, from 1.2492 to 1.3492. Feels meagre. Yields to the fingers like cork, and is somewhat elastic. Colour white; sometimes with a shade of red or yellow; sometimes of a yellow or brown colour

Ligniform asbestus. Colour wood brown, which passes into yellow. Opaque. Very soft. Somewhat flexible, but not elastic. Adheres to the tongue. Feels harsh.

A specimen of the common asbestus, analyzed by Bergmann, contained

63.9	silica
16.0	carbonat of magnesia
12.3	carbonat of lime
6.0	oxyde of iron
1.1	alumina
99.8	

A specimen of the flexible asbestus yielded to the same chymist,

64.0	silica
17.2	carbonat of magnesia
13.9	carbonat of lime
2.7	alumina
2.2	oxyde of iron
100.0	

A specimen of the elastic asbestus contained, according to the same analysis,

56.2	silica
26.1	carbonat of magnesia
12.7	carbonat of lime
3.0	iron
2.0	alumina
100.0	

Twelve different specimens of asbestus, analyzed by Bergmann, yielded the same ingredients, differing a little in their proportions.

Sp. 2. Actinote.

Strahlstein of Werner, except the glassy; Rayonante of Saussure and Brochante. Actinolite, asbestinite, asbestoid of Kirwan. Actinote of Hauy.

This mineral occurs in the primitive rocks, and is usually mixed with those stones which contain a notable portion of magnesia. It is found both massive and crystalized. The primitive form of its crystals, according to Hauy, is a four sided prism whose bases are rhombs, and which he presumes to be the same with the primitive form of hornblende. It occurs in six-sided prisms, in needles, and in small plates. Colour most commonly greenish. Texture radiated, rays diverging from a centre. Fragments undeterminate. Transparency 1; often opaque. Difficult to break. Specific gravity 2.916 to 3.31. Fusible before the blowpipe. It is divided into two subspecies.

ASCARINE, a genus of the dioecia monandria class and order. The essential character is, calyx ament, filiform: corolla none: male, anther worm shaped: female, style none: stigma three lobed drupe. There is one species, a native of the Society Isles.

ASCARIS, or Ascarides, a genus belonging to the class of vermes, and the order of vermes intestinæ. These insects are found in the bodies of animals; have a round and elastic body, tapering toward each extremity; three protuberances at the head; the tail obtuse or subulate; and the intestines spiral, milky white, and pellucid: they are of the two sexes, and very prolific; but their origin is still a matter of profound obscurity. There are two species, *viz.*

1. Ascaris lumbricoides is about the same length with the lumbricus terrestris, or common earth worm; but it wants the protuberant ring toward the middle of the body, the only mark by which they can properly be distinguished. The body of the lumbricoides is cylindrical, and subulated at each extremity; but the tail is somewhat triangular. The lumbricoides is the worm which is most commonly found in the human intestines. It is viviparous, and produces vast numbers.

2. Ascaris vermicularis, see Plate XV. Nat. Hist. fig. 42, 43, with faint annular rugæ, and the mouth transverse, is about a quarter of an inch long, and thicker at one end than the other. It is found in boggy places, in the roots of putrid plants, and very frequently in the rectum of children and horses. It emaciates children greatly, and is sometimes vomited up.

ASCENDANT, Ascendent, or Ascending Line, among lawyers, is meant of ancestors, or such relations as are nearer the root of the family. Such are the father, grandfather, great uncle, &c. Marriage is always forbidden between the ascendants and descendants in a right line.

ASCENDING, in astronomy, is said of such stars as are rising above the horizon, in any parallel of the equator. Thus likewise, 1. Ascending latitude, is the latitude of a planet when going toward the north pole. 2. Ascending node, is that point of a planet's orbit, wherein it passes the ecliptic, to proceed northward. This is otherwise called the northern node, and represented by this character ☊.

Ascending *vessels*, in anatomy, those which carry the blood upward, as the aorta ascendens, and vena cava ascendens. See Anatomy.

ASCENSION, in astronomy, the rising of the sun or a star, or any part of the equinoctial with it, above the horizon, is either right or oblique.

Right ascension is that degree of the equator, reckoned from the beginning of Aries, which rises with the sun or a star, in a right sphere. It is found by the following proportion: as the radius, to the cosine of the sun or star's greatest declination, so is the tangent of the distance from Aries to Libra, to the tangent of right ascension.

Oblique ascension is that degree and minute of the equinoctial, counting from the beginning of Aries, which rises with the centre of the sun or a star, or which comes to the horizon at the same time as the sun or star, in an oblique sphere. In order to find the oblique ascension, we must find the ascensional difference.

The arch of right ascension coincides with the right ascension itself, and is the same in all parts of the globe. The arch of oblique ascension coincides with the oblique ascension, and changes according to the latitude of places.

The sun's right ascension in time, is useful to the practical astronomer in observatories, who adjusts his clock by sidereal time. It serves to convert apparent to sidereal time; as that of an eclipse of Jupiter's satellites, in order to know at what time it may be expected to happen by his clock. For this purpose, the sun's right ascension at the preceding noon, together with the increase of right

ascension from noon, must be added to the apparent time of the phenomenon set down in the ephemeris. The sun's right ascension in time serves also for computing the apparent time of a known star's passing the meridian: for, subtract the sun's right ascension in time at noon, from the star's right ascension in time, the remainder is the apparent time of the star's passing the meridian nearly; from which the proportion at part of the daily increase of the sun's right ascension from this apparent time from noon, being subtracted, leaves the correct time of the star's passing the meridian. The sun's right ascension in time is also useful for computing the time of the moon and planets passing the meridian.

ASCENSIONAL DIFFERENCE, the difference between the right and oblique ascension of any point in the heavens; or it is the space of time that the sun rises or sets before or after six o'clock.

The ascensional difference may be found by this proportion, *viz.* As the radius is to the latitude of the place, so is the tangent of the sun's declination, to the sine of the ascensional difference; by subtracting of which from the right ascension, when the sun is in the northern signs, and adding it when the sun is in the southern ones, you will find the oblique ascension.

ASCENT, in logic, a kind of argumentation, in which we rise from particulars to universals.

ASCETICS, in church history, such Christians in the primitive church as inured themselves to great degrees of abstinence and fasting, in order to subdue their passions. In short, every kind of uncommon piety laid claim to the name ascetic.

ASCII, an appellation given to those inhabitants of the earth, who, at certain seasons of the year, have no shadow: such are all the inhabitants of the torrid zone, when the sun is vertical to them.

ASCIDIA, the name of a genus of vermes, the body of which is fixed, roundish, and apparently issuing from a sheath; the apertures two, generally placed near the summit, one below the other. These creatures are more or less gelatinous, and have the power of contracting and dilating themselves at pleasure; some of them are furnished with a long stem, but most of them are sessile. There are six species, as the papiliosa, &c. See Plate X. Nat. Hist. fig. 40.

ASCITÆ, a sect of Christians in the second century, who introduced a kind of bacchanals into their assemblies, and danced round an inflated bag or skin, saying, "these are the new bottles, filled with new wine," as referred to by Jesus Christ.

ASCITES, in medicine, the common dropsy. See MEDICINE.

ASCIUM, a genus of the polyandria monogynia class and order. The essential character is, calyx five leaved, coriaceous; corolla five petalled; berry one celled, many seeds. There is one species, a tree of Guiana.

ASCLEPIAD, in ancient poetry, a verse composed of four feet, the first of which is a spondee, the second a choriambus, and the two last dactyls; or of four feet and a cæsura, the first a spondee, the second a dactyle, after which comes the cæsura, then the two dactyls, as

Mæcenas atavis edite regibus.

ASCLEPIAS, SWALLOW WORT: a genus of the digynia order, and pentandria class of plants; and in the natural method ranking under the 30th order, *contortæ*. The generic character is taken from five oval, concave, hornlike nectaria, which are found in the flower. There are 34 species, of which the following are the most remarkable, *viz.*

1. Asclepias alba, or common swallow wort, a native of the south of France, Spain, and Italy.

2. Asclepias Curassavica, or bastard ipecacuanha, is a native of the warm parts of America. It rises to the height of five or six feet, with upright stems; the flowers are of a scarlet colour, and the horny nectariums in the middle are of a bright saffron, and there is a succession of flowers on the same plant from June to October. This species is tender, and must be preserved in a stove room.

3. Asclepias Syriaca, or greater Syrian dogsbane, is a perennial plant; the flowers are a bright purple colour.

The root of the first species is used in medicine, and is esteemed sudorific and diuretic. Its sensible qualities resemble those of valerian, which is preferred to it. The milky juice of the plant is considered as poisonous.

ASCODRUTÆ, in church history, a sect of gnostics, who placed all religion in knowledge; and under pretence of spiritual worship, would admit of no external or corporeal symbols whatever.

ASCOLIA, in Grecian antiquity, a festival celebrated by the Athenian husbandmen in honour of Bacchus, to whom they sacrificed a he goat, because that animal destroys the vines. Out of the victim's skin, it was customary to make a bottle, which, being filled with oil and wine, fell as a reward to him who first fixed himself upon it with one foot.

ASCRIPTITI, or adscriptitii, were a description of villains, who, coming from abroad, settled in the lands of some new lord, whose servants or subjects they became, being annexed to the lands, and like other villains transferred and sold with him.

ASCYRUM, Peter's wort, a genus of the polyandria order, and polyadelphia class of plants; and in the natural method ranking under the 20th order, rotaceæ. The calyx consists of four leaves; the corolla has four petals; the filaments are numerous, and divided into four boundaries. There are three species, *viz.*

1. Ascyrum crux Andreæ. 2. Ascyrum hypericoides. 3. Ascyrum villosum: all natives of the West Indies or America.

ASH. See FRAXINUS.

ASH, *mountain*. See SORBUS.

ASH, *poison*. See RHUS.

ASHES, the earthy part of wood and other combustibles, remaining after they are consumed by fire. These, if produced from a vegetable, are of a white colour, and saltish taste, a few instances excepted; and when boiled with fair water, yield a lixivium of an acrimonious, alkaline, fiery, urinous taste. The ashes of all vegetables are vitrifiable, and are found to contain some iron.

Ashes of all kinds contain an alkaline salt, and are an excellent manure for cold and wet ground. They are also of considerable use in making lixiviums or lyes, for the purposes of medicine, bleaching, and for sugar works: and are distinguished by various names; as pot ashes, pearl ashes, wood ashes, and weed ashes. See POTASS, &c.

ASLANI, in commerce, a silver coin, worth from 115 to 120 aspers. See ASPER.

ASP in zoology. See COLUBER.

ASPALATHUS, *African broom:* a genus of the decandria order, belonging to the diadelphia class of plants: and in the natural method ranking under the 32d order, papilionaceæ. The calyx consists of 5 divisions: the pod is oval and contains 2 seeds. Of this genus there are 37 species; all of which are natives of warm climates, and must be preserved in stoves by those who would cultivate them here. The rose wood, whence the oleum Rhodii is obtained, is one of the species, but of which we have yet had no particular description. This wood was anciently in much repute, as an astringent; but it is now used chiefly as a perfume.

ASPARAGUS, a genus of the monogynia order and hexandria class of plants; and in the natural method, ranking under the 11th order, sarmentaceæ. The calyx is quinquepartite, and erect; the three inferior petals are bent outward; the berry has three cells, and contains two seeds. There are 13 species; but the only one cultivated in the gardens is the common asparagus, with an upright herbaceous stalk, bristly leaves, and equal stipula. The other species are kept only for the sake of variety.

The garden asparagus is cultivated from seed. The manner of saving it is this: mark with a stick some of the fairest buds; and when they are run to berry, and the stalks begin to dry and wither, cut them up; rub off the berries into a tub, and pouring water upon them, rub them about with your hands; the husks will break and let out the seed, and will swim away with the water, in pouring it off; so that in repeating this two or three times, the seeds will be clean washed, and found at the bottom of the tub. These must be dried, and in the beginning of February sown on a bed of rich earth. They must not be sown too thick, and must be trod into the ground, and the earth raked over them smooth; in October, when the stalks are withered and dry, a little rotten dung must be spread half an inch thick over the whole surface of the bed. Next spring, the plants will be fit to plant out; the ground must therefore be prepared for them by trenching it well, and burying a large quantity of rotten dung in the trenches, so that it may lie at least 6 inches below the surface of the ground: when this is done level the whole plot. The asparagus is to be planted out in the beginning of March, if the soil is dry, and the season forward; but in a wet soil, it is better to wait till the beginning of April, which is about the season that the plants are beginning to shoot. The season being now come, the roots may be placed two inches under the surface of the ground; and between every four rows, a space of two feet and a half should be left for walking in, to cut the asparagus. The second spring after planting, some of the young asparagus may be cut for the table. But the larger shoots should only be taken, and these should be cut at two inches under the ground. As some people however are very fond of early asparagus, the following directions are given, by which it may be obtained any time in winter: plant some good roots of one year old in a moist rich soil, about eight inches apart; the second and third year after planting, they will be ready to take up for hotbeds; these should be made pretty strong, about three feet thick, with new stable dung that has fermented a week or more; the beds must be covered with earth six inches thick; then against a ridge made at one end, begin to lay in your plants without trimming or cutting the fibres, and between every row lay a little ridge of fine earth, and proceed thus till the bed is planted; then cover the bed two inches thick with earth, and encompass it with a straw band; and in a week, or as the bed is in the temper, put on the frames and glasses, and lay on three inches thick of fresh earth over the beds, and give them air and add fresh heat to them as it requires. These beds may be made from November till March.

ASPECT, in astronomy, denotes the situation of planets and stars, with respect to each other; whereof we find mention of five kinds: 1. Sextile aspect is when the planets or stars are 60 degrees distant, and marked thus *. 2. The quartile or quadrate when they are 90 degrees distant, marked □. 3. Trine when 120 degrees distant, marked △. 4. Opposition when 180 degrees distant, marked ☍. And, 5. Conjunction, when both in the same degree, marked ☌.

Kepler, who added eight new ones, defines aspect to be the angle formed by the rays of two stars meeting on the earth, whereby their good or bad influence is measured: for it ought to be observed, that these aspects being first introduced by astrologers, were distinguished into benign, malignant, and indifferent; the quartile and opposition being accounted malign, the trine and sextile benign or friendly, and the conjunction indifferent.

ASPECT, *double*, in painting, is used where a single figure is so contrived, as to represent two or more different objects, either by changing the position of the eye, or by means of angular glasses.

ASPECT, in a maritime sense, is the view or profile of land or coast, and contains the figure or representation of the borders of any particular part of the sea. These figures and representations may be found in all the ruttiers or directories for the seacoast. The Italians call them *demonstratione*. By means of this knowledge you may ascertain whether the land round the shore is high; if the coast itself is steep or sloping; bent in the form of an arc, or extended in straight lines; round at the top, or rising to a point. Every thing, in a word, is brought in a correct state before the eye, as far as regards harbours, bogs, gulfs, adjacent churches, trees, windmills, &c.

ASPECT, *menacing*. An army is said to hold a menacing aspect, when by advanced movements or positions it gives the opposing enemy cause to apprehend offensive operations.

ASPECT, *military*. A country is said to have a military aspect, when its general situation presents appropriate obstacles or facilities for an army acting on the offensive or defensive.

ASPECT, *imposing*. An army is said to have an imposing aspect, when it appears stronger than it really is. This appearance is often assumed for the purpose of deceiving an enemy, and may not improperly be considered as a principal feint in war.

ASPEN *tree*. See POPULUS.

ASPER, in grammar, an accent peculiar to the Greek language, marked thus (') and importing that the letters over which it is placed ought to be strongly aspirated, or pronounced as if an *h* was joined with them.

ASPER, or *aspre*, in commerce, a Turkish coin, three of which make a medine, and worth something more than our halfpenny.

ASPERIFOLIATE, or *asperifolius*, among botanists, such plants as are rough leaved. Of this kind are bugloss, borage, &c.

ASPERUGO, *small wild bugloss*, a genus of the pentandria monogynia class; and in the natural method ranking under the asperifoliæ. The calyx of the fruit is compressed, with folds flatly parallel, and sinuous. There are two species, *viz.*

1. Asperugo *Ægyptiaca*, a native of Egypt.

2. Asperugo *procumbens*, or wild bugloss, a native of Britain; which is eaten by horses, goats, sheep, and swine; but cows are not fond of it.

ASPERULA, *woodroof*, a genus of the monogynia and hexandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The corolla is infundibuliform; and the capsule contains two globular seeds. There are eleven species, two of which grow wild in England, *viz.*

1. Asperula *cynanchica*, found on chalky hills. The roots are used for dyeing red in Sweden.

2. Asperula *odorata*, a low umbelliferous plant, growing wild in woods and copses, and flowering in May. It has an exceeding pleasant smell, which is improved by moderate exsiccation. It imparts its flavour to vinous liquors. Asperula is supposed to attenuate viscid humours, and is recommended in obstructions in the liver and biliary ducts, and by some in epilepsies and palsies; modern practice has nevertheless rejected it. The smell of it is said to drive away ticks and other insects.

ASPHALTUM. See Bitumen.

ASPHODELUS, *asphodel*, or *king's spear*, a genus of the monogynia order, belonging to the hexandria class of plants. The calyx is divided into six parts; and the nectarium consists of six valves covering the nectarium. There are five species, *viz.*

1. Asphodelus *ramosus*, or *white asphodel*. The leaves are long; the stalks rise to above three feet high, and divide into several spreading branches; these are terminated by loose spikes of white flowers.

2. Asphodelus *luteus*, or *common yellow asphodel*, has strong round single stalks near three feet high, with yellow star shaped flowers, which appear in June.

3. Asphodelus *fistulosus*, or *onion leaved asphodel*, is an annual plant, the flowers of which are white.

ASPIRATE, in grammar, denotes words marked with the asper.

ASPIRATION, among grammarians, is used to denote the pronouncing a syllable with some vehemence; as these words beginning with the letter H, *hear*, *heat*, which are pronounced more softly without the H, as *ear*, *eat*.

ASPIS. See Coluber.

ASPLENIUM, *milt waste* or *spleen wort*, in botany, a genus of cryptogamious plants of the order filices, the fructification of which is arranged in clusters, and disposed in form of straight lines, under the disk of the leaf.

This genus comprehends 47 species, natives of different countries, some of which were formerly used in medicine, but are now rejected.

ASS, *feast of*, a festival, celebrated during the dark ages, in commemoration of the Virgin Mary's flight. On this occasion, a young girl, richly dressed, with a child in her arms, was set upon an ass. The beast was led to the altar, where mass was said with great pomp. The ass was taught to kneel, and a hymn was sung in his praise. As soon as the ceremony was ended, the priest and the people brayed in imitation of the ass. This was esteemed an act of devotion, and performed by authority of the church.

Ass, *asinus*, in zoology. See Equus.

ASSARON, or *omer*, a measure of capacity, in use among the Hebrews, containing five pints. It was the measure of manna which God appointed for every Israelite.

ASSAULT, in law, a violent injury offered to a man's person: it may be committed by offering a blow, or a threatening speech. In case a person threatens to beat another, or lies in wait to do it, if the other is hindered in his business, and receives loss, it will be an assault, for which an action may be brought, and damages recovered; or the party threatening may be bound over to the peace. Not only striking, but thrusting, pushing, casting stones, or throwing drink in the face of any person, are deemed assaults.

In all which cases, a man may plead in his justification, the defence of his person (but not of his goods) or of his father, mother, wife, child, master, &c.

ASSAYING, is the art of finding how much pure metal is contained in every ore, or the proportion of the several ingredients of any mixed metal, which is done in the following manner:

1. *Gold.* To obtain pure gold we have only to dissolve the gold of commerce in nitromuriatic acid, and precipitate the metal by dropping in a very diluted solution of sulphat of iron; the powder which precipitates, after being well washed and dried, is pure gold.

2. *Platinum.* Platinum can scarcely be obtained perfectly pure in the metallic state, at least in any considerable quantity; because a sufficient heat for melting it cannot be obtained. But its oxide may be procured quite pure from the muriat of platinum and Ammonia, prepared by the rules to be hereafter laid down. This salt is to be decomposed by a violent heat, and the residuum, if necessary, may be re-dissolved in nitromuriatic acid, and precipitated with soda.

3. *Silver.* Dissolve the silver of commerce in nitric acid, and precipitate with a diluted solution of sulphat of iron. The precipitate is pure silver. Or precipitate with common salt; form the precipitate into a paste with soda; put it into a crucible lined with soda, and fuse it with a brisk heat. This process gives a button of pure silver.

4. *Mercury* may be obtained pure by distilling a mixture of two parts cinnabar and one part of iron filings in an iron retort. The mercury comes over, and the sulphuret of iron remains behind; or the oxymuriat of mercury may be decomposed by ammonia, and the precipitate heated either by itself or mixed with oil.

5. *Copper* may be dissolved in muriatic acid, and the copper precipitated by a polished plate of iron; or the black oxide of copper, obtained by decomposing cuprated ammonia, may be melted with its own weight of pounded glass and pitch.

6. *Iron* can scarcely be obtained perfectly free from carbon. The processes for obtaining it as pure as possible will be given hereafter.

7. *Tin* may be obtained pure by solution in strong nitric acid; the white oxide of tin is formed, which is insoluble. Let it be digested first with muriatic acid, and afterward with aqua regia. Mix the oxide thus purified with its weight of pitch and a little borax, and melt it in a crucible.

8. *Lead* may be obtained pure from the carbonat by solution in diluted nitric acid and precipitation by a cylinder of zinc; from the sulphuret by solution in nitric acid, mixing the solution with muriatic acid, and crystalizing. The crystals of muriat of lead are to be dissolved in boiling water, and then evaporated to dryness. The mass is to be melted in a crucible with $2\frac{1}{2}$ times its weight of black flux.

9. Chymists have hitherto failed in their attempts to obtain *nickel* in a state of absolute purity. The great difficulty is to separate it from cobalt; upon which all reagents have nearly the same action. The following ingenious method has been lately proposed by Mr. Phillips: dissolve the nickel of commerce in nitric acid to saturation. Throw down the arsenic acid by nitrat of lead. Then, after filtration, add an excess of nitric acid, and introduce an iron rod into the solution to throw down the copper. After this, precipitate the whole by carbonat of potass, and digest the precipitate in liquid ammonia. The cobalt and nickel are taken up; the iron and lead remain. Dilute the solution with water; add an excess of ammonia; then pour potass into the solution. The cobalt remains in solution, but the nickel precipitates in the state of a pure oxide, and may be reduced by exposure to a strong heat with charcoal.

10. *Zinc* may be dissolved in sulphuric acid, and a plate of zinc allowed to remain for a considerable time in the solution. It is then to be filtered, and the zinc to be precipitated with soda. The precipitate, edulcorated and dried, is to be mixed with half its weight of pure charcoal, and distilled in an earthen ware retort. The zinc is found pure in the neck of the retort.

11. *Antimony* may be dissolved in nitromuriatic acid, and precipitated by the affusion of water. The precipitate is to be mixed with twice its weight of tartar, and fused in a crucible. A button of pure antimony is obtained.

12. *Bismuth*, if impure, may be dissolved in nitric acid, and precipitated by water. The edulcorated precipitate, formed into a paste with oil, and rapidly fused with black flux, gives a button of pure bismuth.

13. *Tellurium* was obtained pure by Klaproth, by forming its oxide into a paste with oil, and heating it to redness in a retort. The metal was rapidly revived.

14. *Arsenic*, in the state of white oxide, may be dissolved in muriatic acid, precipitated by the affusion of water, re-dissolved, and a plate of zinc inserted into the solution, mixing with it at the same time a little alcohol. The arsenic is precipitated in the metallic state.

15. *Cobalt* may be obtained pure in all likelihood by following the process proposed by Mr. Phillips for the purification of nickel. The following is a much cheaper process recommended by Trommsdorf: mix a pound of the best smalt with four ounces of nitre and two ounces of charcoal powder, and throw the mixture at intervals into a red hot crucible. This process is to be repeated three times. The mixture is then to be kept in a strong heat for an hour, stirred well, then mixed with four ounces of black flux, and kept in the strong heat of a forge for an hour longer. The cobalt, reduced by this treatment, is still impure. It is to be mixed again with thrice its weight of nitre, and deflagrated in a red hot crucible by small portions at a time. By this process the iron is peroxidized, and the arsenic acidified. The mass is to be well washed, and the oxide of cobalt separated by filtration. This oxide is to be dissolved in nitric acid, and evaporated to dryness. A fresh portion of acid is to be added, and the mass exposed to a moderate heat. Dilute with water, and filter to separate the remains of the iron. Precipitate by pure potass, and reduce the oxide.

16. *Manganese.* Digest the black oxide of manganese repeatedly in nitric acid; then mix it with sugar, and dissolve it in nitric acid. Filter the solution, precipitate by an alkali, form the white oxide thus obtained into a paste with oil, and put it into a crucible well lined with charcoal. Expose the crucible for an hour to the strongest heat of a forge.

17. *Tungsten* was obtained by Elhuyart by heating the yellow oxide violently in a crucible lined with charcoal: but this process has not succeeded with other chymists.

18. *Molybdenum* may be obtained by forming molybdic acid into a paste with oil, and heating it violently in a crucible lined with charcoal.

19. *Uranium* is procured by forming the yellow oxide of that metal into a paste with oil, drying it in a moderate heat, putting it into a crucible lined with charcoal, with a little lampblack strewed over it. After luting on the cover, it is to be heated at first gently, and then violently, for three quarters of an hour.

20. *Titanium*, in a very small proportion indeed, was obtained in the metallic state, by mixing together 100 parts of the red oxide of the metal, 50 parts of borax, and five parts of charcoal, and forming the mixture into a paste with oil. This paste was put into a crucible lined with charcoal, and exposed for an hour and a half to the violent heat of a forge.

21. *Chromium* was obtained by Vauquelin in the metallic state, by putting a portion of chromic acid into a charcoal crucible, enclosed in a common crucible lined with charcoal, and exposing it for an hour to the violent heat of a forge.

ASSAYING of weights and measures, the examining the common weights and measures by the clerk of the market.

ASSEMBLY, in the military art, the second beating of a drum before a march; at which the soldiers strike their tents, roll them up, and stand to arms.

ASSEMBLIES of the clergy are called convocations, synods, councils; the annual meeting of the church of Scotland is called a general assembly.

ASSES, *order of*, a denomination of Mathurins, or Trinitarians; so called because they were obliged, in travelling, to ride on asses, not horses.

ASSESSOR, an inferior officer of justice, appointed chiefly to assist the ordinary judge with his opinion and advice.

ASSESSOR is also one who assesses or settles taxes, and other public dues.

ASSETS, in law, goods or property in the hands of a person, with which he is enabled to discharge an obligation imposed upon him as executor, &c. Assets may be real or personal.

ASSIENTO, a Spanish word, signifying a farm, in commerce, is used for a bargain between the king of Spain and other powers, for importing negroes into the Spanish dominions in America, and particularly to Buenos Ayres. The first assiento was made by the French Guinea company; and by the treaty of Utrecht, transferred to the English, who were to furnish 4800 negroes annually.

ASSIGN, in common law, a person to whom a thing is assigned or made over.

ASSIGNEE, in law, a person appointed by another to do an act, transact some business, or enjoy a particular commodity.

Assignees may be by deed or by law: by deed, where the lessee of a farm assigns the same to another; by law, where the law makes an assignee, without any appointment of the person entitled, as an executor is assignee in law to the testator, and an administrator to an intestate. But when there is assignee by deed, the assignee in law is not allowed.

It is most commonly applied to those creditors of a bankrupt who are appointed by the rest to manage for them, and consequently have the bankrupt's estate assigned over to them.

ASSIGNING, in a special sense, is used to set forth and point at, as to assign an error, to assign false judgment, to assign waste; in which cases it must be shown wherein the error is committed, where and how the judgment is unjust, and where the waste is committed.

ASSIGNMENT, in law, differs from a lease in this, that by a lease a man grants an interest less than his own; in assignment he grants the whole property. 2 Blacks. 326.

ASSIMILATION, in physics, is that motion by which bodies convert other bodies related to them, or at least such as are prepared to be converted, into their own substance and nature.

ASSISE, in old law books, is defined to be an assembly of knights and other substantial men, with the justice, in a certain place, and at a certain time: but the word in its present acceptation is used for the court, place, or time when and where the writs and processes, whether civil or criminal, are decided by judges and jury. In this signification, assise is either general, when judges make their respective circuits, with commission to take all assise; or special where a commission is granted to particular persons for taking an assise upon one or two disseisins only. By Magna Charta, justices shall be sent through every county, once a year, who, with the knights of the several shires, shall take assise of novel disseisin: and as to the general assise, all the counties of England are divided into six circuits, and two judges are assigned by the king's commission, to every circuit, who now hold the assises twice a year, in every county, except Middlesex, where the courts of record sit, and the counties palatine. These judges have five several commissions: 1. Of oyer and terminer, by which they are empowered to try treasons, felonies, &c. 2. Of gaol delivery, which empowers them to try every prisoner *in gaol*, for whatever offence he be committed. 3. Of assise, which gives them power to do right upon writs brought by persons wrongfully thrust out of their lands and possessions. 4. Of nisi prius, by which civil causes come to issue in the courts above, are tried in the vacation by a jury of twelve men, in the county where the cause of action arises. 5. A commission of the peace, in every county of the circuit: and all justices of peace of the county and sheriffs are to attend upon the judges, otherwise they shall be fined.

Assise is used in several other significations; as, 1. for a jury where assises of novel disseisin are tried, and the pannels of assise shall be arraigned. See the next article. 2. For a writ for recovery of the possession of things immoveable, of which a person and his ancestors have been disseised. 3. For an ordinance or statute, as the assise of the forest, a statute concerning orders to be observed in the king's forest. 4. For a quantity of wheat, bread, &c. prescribed by a statute; as we say, when wheat is of such a price, bread shall be of such an assise.

Assise *of novel disseisin* is a writ that lies where a tenant in fee simple, fee tail, or for term of life, is put out and disseised of his lands, tenements, rents, common of pasture, common way, &c. A writ of assise may sometimes be had by a person, when he cannot have trespass *vi et armis;* as where a lord enters on lands, and distrains his tenant so often, when nothing is due, that the tenant is disturbed in manuring his lands; in such case he may have *assise de souvent fois distress;* but he cannot bring trespass against his lord.

Assise *of mort d'ancestor* is a writ which lies where a person's father, mother, brother, &c. died seised of lands and tenements in fee, and, after either of their deaths, a stranger abateth.

Assise *of utrum* lies for a parson against a layman, or a layman against a parson, for lands or tenements doubtful whether they are lay fee or free alms.

ASSOCIATION *of ideas* is where two or more ideas constantly and immediately follow one another, so that the one shall almost infallibly produce the other, whether there is any natural relation between them or not.

Association, in law, is a writ or patent sent by the king, either of his own motion, or at the suit of the plaintiff, to the judges of assise, to have others associated to them, to take the assise, &c.

ASSONIA, in botany, a genus of the class and order monadelphia dodecandria. The essential character is, calyx double, outer one leaved or three leaved, inner one leaved; corolla five petalled, no tube affixed to the pitcher of stamens; filament connected in form of a pitcher, with petal shaped straps between; style one or five; capsule five celled; seeds not winged.

There are eleven species, the most remarkable of which is the A. populnea, a middle sized tree, growing in the isle of Bourbon, and resembling the hibiscus populneus. The wood is sweet scented, and blue in the middle.

ASSUMPSIT, a voluntary or verbal promise, where by a person assumes, or takes upon him to perform or pay any thing to another. All assumpsits must be for some valuable consideration; and they are either *express* or *implied*. Express is by direct agreement either by word or note without seal: implied, when any person becomes legally indebted to another for goods sold, the law implies a promise that he will pay his debt; and if he does not pay it, the writ *indebitatus assumpsit* lies against him:

and will lie for goods sold and delivered to a stranger, or third person, at the request of the defendant: but the price agreed on must be proved, otherwise that action does not lie.

ASSUMPTIVE ARMS, in heraldry, are such as a person has a right to assume, with the approbation of his sovereign, and of the heralds.

ASSURANCE, a contract by which the assurer undertakes, in consideration of a premium equivalent to the hazard run, to indemnify the person assured against certain perils or losses, or against some particular event. The practice of entering into such engagements, which originated about the year 1182, and has been greatly extended as its utility has become more understood, gives great security to the fortunes of private people, by dividing among many that loss which would ruin an individual.

The instrument by which this contract of indemnity is effected between the assurer and the assured is called a policy; and is not, like most contracts, signed by both parties, but only by the assurer, who on that account, it is supposed, is denominated an underwriter.

Assurances may be distinguished into marine assurances, assurances upon lives, and assurances against fire.

Marine assurance is an indemnity against those perils to which ships and goods are exposed in the course of their voyage from one place to another, whether arising from the dangers of the seas, fire, capture by enemies or pirates, detention by the government of any country, or from any fraudulent act of the master or mariners, such as running away with the ship, carrying her a course different from their orders, sinking her, deserting her, or embezzling the cargo. Assurances of this kind being of peculiar importance to the commercial interests of this country, and many frauds having been committed in this business by persons receiving premiums who were totally unable to fulfil their engagements, an act of parliament was passed in the reign of George I. establishing two corporations with adequate capitals for carrying on this business, and prohibiting any other society or partnership whatsoever from making marine assurances or lending money on bottomry. The two companies are, the Royal Exchange Assurance and the London Assurance, who both engage very extensively in this species of assurance; but as from their superior responsibility they generally require a somewhat higher premium than private underwriters, many persons prefer effecting their assurances with the latter; this business, in London, is carried on chiefly in a set of rooms called Lloyd's coffeehouse, over the Royal Exchange, where four or five hundred underwriters assemble daily. Persons having an assurance to make, generally employ a broker, who having prepared a policy, carries it to an underwriter, whom he considers a responsible person, who if he considers the risk offered an eligible one to undertake, signs his name at the bottom of the policy, mentioning the sum he agrees to be answerable for; it is then taken to another, and so on till the whole sum mentioned in the policy is completed. The premium paid depends on the length of the voyage, the condition of the vessel, the season of the year, peace or war, and many other circumstances; of course it is very different at different periods.

Life assurance is a contract by which the underwriter for a certain sum, proportioned to the age, profession, and other circumstances of the person whose life is the object of assurance, engages that if such person shall die within the time limited in the policy, he will pay a sum of money to him in whose favour the policy was granted. The advantages resulting from such assurances are very numerous, *viz.*

Persons deriving life incomes from church preferment, public offices, or any other civil or military employment, may thus, by appropriating part of their income to provide an annual payment, prevent the distress which their death would otherwise occasion to their family or dependents.

A person whose income depends on the life of another, may, by making an annual payment, secure an adequate sum to himself or representative, at the death of another person; or he may secure such sum to be paid only in case he survives such other person. For instance,

A person aged 20 pays annually

l.	*s.*	*d.*		
1	17	0	to secure 100*l.* to be paid him in case he survives another person aged	20
2	19	10		40
5	18	1		60

A person aged 60 pays annually

l.	*s.*	*d.*		
1	12	1	to secure 100*l.* to be paid him in case he survives another person aged	20
2	9	4		40
5	2	4		60

In cases, also, where a debtor cannot give adequate security to his creditor, an annual payment to the company will enable the creditor to receive his debt in the event of the death of the debtor. Tenants for life may thus obviate the difficulty of raising money on securities which must become void upon their decease.

Persons holding offices or employments depending on the lives of others, may in the same manner secure themselves from loss on the event of the death of the person on whose life their office or employments may depend.

Persons sinking a sum of money in the purchase of an employment or office, in establishing a trade or manufacture, or in carrying on agricultural improvements, may secure the repayment of such sum to their family or other representatives.

Persons entering into marriage, who, in consideration of the fortune received, may be required to settle a sum of money to be paid at their decease, may, by making an annual or single payment to the company, provide a fund for a marriage settlement, and thus secure a provision for a widow or children.

Persons holding leases on lives may provide the fine payable on the renewal of such leases.

Persons who are entitled, by purchase or otherwise, to an annuity on their own life, or the lives of others, or the joint lives of themselves and others, may secure the full value of such annuity, to be received at the death of the parties on whose lives the annuity depends.

Those who, on their surviving another, will become possessed of an estate, annuity, legacy, office, place, or preferment, ecclesiastical, military, or civil, may either provide a more adequate security than they could otherwise do for money advanced, or may secure an equivalent

sum to their family, or other representative, to be paid in the event of such survivorship not taking place.

The premium paid for assuring a life, is computed from the probability of the failure of such a life, as deduced from bills of mortality, and the rate of interest at which money can be improved during the probable continuance of the life; those who wish to investigate this subject, may consult Simpson on Annuities and Reversions, Dr. Price's Treatise on Reversionary Payments, and the Doctrine of Annuities and Assurances on Lives, &c. by W. Morgan, actuary to the Society for Equitable Assurance on Lives and Survivorship. The premium for an assurance for a certain term of years, or for the whole continuance of life, is generally paid annually, but sometimes in a gross sum. The following is a specimen of the annual premium required for assuring 100*l.* by most of the societies that undertake this species of assurance.

Age.	One Year.			Seven Years.			Whole Life.		
	l.	*s.*	*d.*	*l.*	*s*	*d.*	*l.*	*s.*	*d.*
10	0	17	9	1	1	5	1	17	7
15	0	17	11	1	2	11	1	18	7
20	1	7	3	1	9	5	2	3	7
25	1	10	7	1	12	1	2	8	1
30	1	13	3	1	14	11	2	13	5
35	1	16	4	1	18	10	2	19	10
40	2	0	8	2	4	1	3	7	11
45	2	6	8	2	10	10	3	17	11
50	2	15	1	3	0	8	4	10	8
55	3	5	0	3	12	0	5	6	4
60	3	18	1	4	7	1	6	7	4
65	4	15	2	5	10	10	7	16	9
70	6	6	1	7	14	4	10	0	4

Assurances on the lives of persons subject to any peculiar hazard; such as persons in the army and navy, or going to foreign parts, are charged with an additional premium proportionate to the extra risk.

The foundation of the contract for a life assurance, is generally, a warrantee that the life to be assured does not exceed a given age, and is in good health at the time of effecting the assurance. There is also usually a stipulation that the assurance shall become void if the person whose life is assured shall depart beyond the limits of Europe, shall die upon the seas, or shall engage in any military or naval service without the consent of the assurers: and when it is an assurance made by a person on his own life, it becomes void if he dies by suicide, duelling, or the hands of justice.

Any person making an assurance on the life of another must be interested therein, speculative assurances being prohibited by 14 George III. c. 48.

Assurances against fire, are made upon houses, warehouses, and all other buildings, household furniture, wearing apparel, merchandise, utensils and stock in trade, ships in harbour, in dock, or while building, and on all other property liable to be consumed by fire; except writings, notes, bonds, money, and a few other similar articles, which the assurers could not undertake to be answerable for, without rendering themselves liable to be grossly defrauded. Assurances against fire are made for a limited period, usually for one or more years, and are distinguished by the assurers into three classes, *viz.*

1. Common assurances are assurances on all manner of buildings, having the walls of brick or stone, and covered with slate, tile, or metal, wherein no hazardous trades are carried on, nor any hazardous goods deposited, and on goods and merchandises not hazardous in such buildings.

2. Hazardous assurances are assurances on timber or plaster buildings, covered with slate, tile, or metal, wherein no hazardous trades are carried on, nor any hazardous goods are deposited; and on goods or merchandises, not hazardous, in such timber or plaster buildings; and also on hazardous trades, such as cabinet and coach makers, carpenters, coopers, bread and biscuit bakers, ship and tallow chandlers, soap makers, innholders, sail makers, maltsters, and stable keepers, carried on in brick or stone buildings covered with slate, tile, or metal; and on hazardous goods, such as hemp, flax, resin, pitch, tar, and turpentine, deposited in such buildings; the stock in trade of apothecaries; also on ships, and all manner of water craft, in harbour, in dock, or while building, and on thatched buildings which have not a chimney, and do not adjoin to any building having a chimney.

3. Doubly hazardous assurances are assurances on any of the aforesaid hazardous trades carried on, or hazardous goods deposited in timber or plaster buildings, covered with slate, tile, or metal; on glass, china, and earthen ware; also in thatched buildings or goods therein, except as in the preceding class; and on saltpetre, with the buildings containing the same.

Assurances on buildings and goods are deemed distinct adventures, so that the premium on goods, so far as it is regulated by the sum assured, is not advanced by reason of any assurance on the building wherein the goods are kept, nor the premium on the building by reason of any assurance on the goods.

The annual premiums usually charged for fire assurances are: common assurances not exceeding 3000*l.* two shillings per cent; hazardous assurances not exceeding 2000*l.* three shillings per cent; doubly hazardous assurances not exceeding 2000*l.* five shillings per cent.

In addition to this charge of the assurers, government have imposed a duty of 2*s.* 6*d.* per cent. per annum on all sums assured against fire.

ASSUROR, a merchant or other person who signs a policy of assurance, and thereby insures a ship, house, or the like.

The assurer is not liable for what damages may arise from the negligence or other faults of the masters or mariners, or even from any defect in the things assured.

ASSURITANI, a branch of the Donatists, who held that the Son was inferior to the Father, and the Holy Ghost to the Son: they rebaptized those who embraced their sect; and asserted that good men only were within the pale of the church.

ASTATI, a sect of Christians, who being the followers of one Sergius, revived the erroneous doctrines of the Manichees. They were remarkable for the inconstancy of their principles.

ASTER, in botany, *star wort*, a genus of the polygamia superflua order and syngenesia class of plants, and in the natural method ranking under the 49th order, compositi radiati. The receptacle is naked, the pappus is simple, the rays of the corolla are more than ten, and the calyx is imbricated. There are 60 species. All of them may be raised from seed; but the greatest part of them

being perennial plants, and increasing at the roots, are generally propagated by parting their roots early in the spring, and they will grow in almost any soil or situation; and the larger sorts increase so fast, that, if not prevented, they will in a little time run over a large space of ground. They grow best in the shade. The lower kinds do not run so much at the root, but should be taken up and transplanted every other year, which will make them produce much fairer flowers. Some few sorts, which are natives of warm climates, will require artificial heat to raise them, if not to preserve them.

ASTERIA, in natural history, a beautiful pellucid gem, of variable colours as viewed in different lights: called also *oculus cati*, or cat's eye.

The variable colours, which are a pale brown and white, seem to be lodged deep in the stone, and shift about as that is moved. It is nearly allied to the opals; from which, however, it is distinguished by its colour and superior hardness.

Asteria is also the name of an extraneous fossil, called in English the star stone.

ASTERIAS, *star fish*, or *sea star*, in zoology, a genus of the order of vermes mollusca. It has a depressed body, covered with a coriaceous coat; is composed of five or more segments, running out from a central part, and furnished with numerous tentacula; and has the mouth in the centre. The conformation of the mouth is this: the under part of each lobe runs toward a point with the rest at the centre of the body; and these several productions of the rays make a sort of lips, the ends of each of which are armed with a number of sharp teeth, which serve to take and convey the food into the body. From this mouth there goes a separate canal to all or many of the rays, which runs through their whole length, and becomes gradually narrower as it approaches the extremity. The tentacula resemble the horns of snails, but serve the animal to walk with. They are capable of being contracted or shortened; and it is only at the creature's moving that they are seen of their full length: at other times no part of them is seen but the extremity of each, which is formed like a sort of button, being somewhat larger than the rest of the horn. Aristotle and Pliny called this genus ἀστηρ, and *stella marina*, from their resemblance to the pictured form of the stars of heaven; and they asserted that they were so exceedingly hot, as instantly to consume whatsoever they touched! The fossil world has been greatly enriched by the fragments and remains of the several pieces of star fish which have been converted into stones. There are many species of this genus: some of 12, 13, and even 14 rays. Most of them are found in our seas. See Plate XV. Nat. Hist. fig. 41.

1. Asterias *caput Medusæ*, or arborescent sea star, has five rays issuing from an angular body: the rays dividing into innumerable branches, growing slender as they recede from the base. These the animal, in swimming, spreads like a net to their full length: and when he perceives any prey within them, draws them in again, thus catching it with all the dexterity of a fisherman. It is an inhabitant of every sea; and is called by some the Magellanic star fish and basket fish. When it extends its rays fully, it forms a circle of near three feet in diameter. The fragments of these rays furnish the fossil entrochi. If we drown this animal in brandy or spirit of wine, and keep the rays flat and expanded in the execution, it is easy to extract by means of a pair of forceps the stomach of the animal whole and entire through the mouth.

2. Asterias *clathatra*, or cancellated sea star, with five short thick rays, hirsute beneath, cancellated above, is found on our coasts, but is rare.

3. Asterias *decacnemos* has ten very slender rays, with numbers of long beards on the sides; the body is small, and surrounded beneath with ten filiform rays.

4. Asterias *glacialis*, with five rays, depressed, broad at the base, yellow, and having a round striated operculum on the back, is the most common: it feeds on oysters, and is very destructive to the beds. See Plate Nat. Hist. fig. 42.

5. Asterias *hispida*, with five rays, broad, angulated at top, and rough with short bristles, is of a brown colour, and is found about Anglesea.

6. Asterias *oculata*, with five smooth rays, dotted or punctured, is of a fine purple colour, and is also found about Anglesea.

7. Asterias *placenta*, with five very broad and membraneous rays, extremely thin and flat, is found about Weymouth.

8. Asterias *spherulata*, with a pentagonal indented body; a small globular bead between the base of each ray; the rays slender, jointed, taper, and hirsute on their sides: is found off Anglesea.

ASTEROIDES, in astronomy, a name given by Dr. Herschel to the new planets, or three small planetary bodies, discovered by the foreign astronomers Piazzi, Olbers, and Harding, which are defined as "celestial bodies either of little or considerable eccentricity round the sun, the plane of which may be inclined to the ecliptic in any angle whatever. The motion may be direct or retrograde; and they may or may not have considerable atmospheres, very small comas, disks, or nuclei." From the observations already made on these bodies, they appear to partake of the several properties by which the planets in general are known and described; and therefore, with justice, some astronomers have objected to this new definition of Dr. Herschel.

ASTEROPODIUM, a kind of extraneous fossil, of the same substance with the asteriæ, or star stones, to which they serve as a base.

ASTHENIA, in medicine, a term employed to denote bodily debility. See Medicine.

ASTHMA, in medicine, a painful, difficult, and laborious respiration, occasioned by intolerable straitness of the lungs, which, as it disturbs the free circulation of the blood through the lungs, endangers a suffocation.

This disorder is attended with violent motions of the diaphragm, abdominal and intercostal muscles, to the very scapula and pinnæ of the nostrils. It is usually divided into pneumonic and convulsive; and is also either continual, or intermitting and periodical, and returns commonly when a sober regimen is not observed.

This disorder proves most violent while the patient is in bed, and in a prone posture, as in that case the contents of the lower belly bearing against the diaphragm, lessen the capacity of the breast, and leave the lungs less room to play. See Medicine.

ASTRAGAL, in architecture, a little round moulding, in form of a ring, serving as an ornament at the tops and bottoms of columns. See ARCHITECTURE.

ASTRAGAL, in gunnery, a round moulding encompassing a cannon, about half a foot from its mouth.

ASTRAGALUS, in botany, *milk vetch*, or *liquorice vetch*, a genus of the decandria order and diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ; the pod is gibbous and bilocular. Of this genus there are 63 species.

ASTRAGALUS *communis*. The common species grows wild upon dry uncultivated places, and is recommended by Mr. Anderson to be cultivated as proper food for cattle.

The astragalus tragacantha is a thorny bush growing in Crete, Asia, and Greece, which yields the gum tragacanth. This is of so strong a body, that a drachm of it will give a pint of water the consistence of a syrup, which a whole ounce of gum arabic is scarcely sufficient to do. Hence its use for forming troches, and for similar purposes, in preference to the other gums.

ASTRAGALUS, in anatomy, called also the *talus*, is the superior and first bone of the foot. See ANATOMY.

ASTRANTIA, *masterwort*, a genus of the digynia order and pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The involucrum is lanceolated, open, equal, and coloured. The species are five, but possess no remarkable properties.

ASTRARIUS *hæres*, in law, is where an ancestor, by conveyance, has settled his heir apparent and family in a house in his life time.

ASTRÆA, in astronomy, the same as Virgo.

ASTRINGENTS, *astringentia*, in pharmacy, medicines of the corroborative class. See PHARMACY.

Astringents are thought by some to act nearly in a similar manner on the simple or dead animal fibre as on the living solid; in both cases thickening and hardening: when applied to the living solid, they produce increase of tone and strength, restrain inordinate actions, and check excessive discharges from any vessels or cavities; and to the dead fibre occasion that density, toughness, imperviousness to water in a greater or lesser degree, and insusceptibility to the common causes of putrefaction, in which consists the process of tanning, or preparation of leather. See TANNING.

ASTRODICTICUM, an astronomical instrument, by means of which many persons are able to view the same star at the same time.

ASTROITES, or *star stone*, in natural history, is so called on account of its resemblance to a star. It is controverted among naturalists, whether they are parts of a petrified marine animal, or, as is more probable, a species of coral buried in the earth. The corals forming these stars are sometimes round, sometimes angular, and their columns are sometimes separated, and sometimes the striæ run into one another.

ASTROLABE, the name for a stereographic projection of the sphere, either upon the plane of the equator, the eye being supposed to be in the pole of the world; or upon the plane of the meridian, when the eye is supposed in the point of intersection of the equinoctial and horizon.

ASTROLABE is also an instrument for taking the altitude of the sun or stars at sea, being a large brass ring, A C B D, Plate XIV. Miscel. fig. 5. the limb of which, or a convenient part thereof A C, is divided into degrees and minutes, with a moveable index F G, which turns upon the centre, and turns two sights; at the zenith is a ring A, to hang it by in time of observation, when you need only to turn the index to the sun, that the rays may pass freely through both sights, and the edge of the index cuts the altitude upon the divided limb. This instrument, though not much in use now, if well made, and of great weight that it may hang the steadier, is as good as most instruments that are used at sea for taking altitudes, especially between the tropics, when the sun comes near the zenith, and in calm weather.

ASTROLOGY, a conjectural science, which absurdly pretended to foretell future events by the situation and different aspects of the heavenly bodies.

ASTROLUS, in natural history, a name given by authors to a white splendid stone, small in size, roundish, and resembling the eyes of fishes.

ASTROMETEOROLOGIA, the art of foretelling the weather and its changes from the aspect of the moon and stars. This is sometimes called meteorological astrology. There is however but little reason to believe that the heavenly bodies have any great influence on our atmosphere. See METEOROLOGY.

ASTRONIUM, in botany, a genus of the class and order dioecia pentandria. The essential character is, male, calyx five leaved; corolla five petalled; female, calyx five leaved; corolla five petalled; styles three; seed one.

There is but one species, a tree, a native of New Spain, abounding in a slight glutinous terebinthine juice, which has a disagreeable smell.

ASTRONOMICAL *place* of a star or planet, is its longitude or place in the ecliptic, reckoned from the beginning of Aries, according to the natural order of the signs.

ASTRONOMY, is a mixed mathematical science, which treats of the heavenly bodies, their motions, periods, eclipses, magnitudes, &c. and of the causes on which they depend.

History of Astronomy. The origin of astronomy is very obscure, and appears to be also very ancient. "There is no doubt," says Cassini, "that astronomy was known even from the commencement of the world. It was not only curiosity which led man to the study of astronomy, but it may be said that necessity itself obliged him to it. For if he did not observe the seasons which result from the apparent changes of the sun's place, it would be impossible to succeed in the practice of agriculture and other useful arts." But astronomy, even if it could be considered as useless to man, derives from its very nature a certain degree of dignity. It is, moreover, upon this that navigation, geography, and chronology, depend. By its aid man passes the seas, and penetrates into foreign climes, becomes acquainted with those which he inhabits, and regulates the dates of ages past.

Hipparchus laid the principal foundation of a methodical astronomy, 147 years before Christ. When an opportunity was given him to observe a new fixed star, he directly made a list of such stars, so that in the next age

they were able to know if one had appeared more than usual. Ptolemy, about 280 years afterward, added his observations to those of Hipparchus, and by the natural advantage which he possessed over his predecessor, he was enabled to rectify greatly the observations that he had made.

Astronomy was very much neglected from this period till after the middle of the 13th century, at which time Alphonsus, king of Castile, formed tables more exact than the preceding. Indeed, a celebrated astronomer having at an early period been sufficiently attentive to observe all the planets in one night, found not one in the place of another, but all according to the tables which had been made by order of the king of Castile. It was not, however, till the 16th century that astronomy derived fresh lustre from the system of Copernicus, published at Nuremberg in 1543, and brought to perfection by Kepler and Galileo; a system so bold and daring, that it produced general astonishment, and yet its truth has been confirmed by the observations of every succeeding age. The surface of the heavens seems to us to be studded with stars; between the fixed stars and us there seem to be other stars which change their situations respectively one toward another, and these all astronomers have agreed in calling *planets*, or wandering stars. The ancient philosophers, who knew so very little even of the movements of the planets, had no evident means to know the true disposition of their orbits; and this is the reason that they vary so greatly in their opinions. They supposed, at first, the earth to be immoveable, as the centre of the universe, and that all the celestial bodies turned about her; which, indeed, was natural for them to believe, without having discussed the proofs to the contrary.

The Babylonians, however, and afterward Pythagoras and his disciples, are said to have considered the earth as a planet, and the sun as immoveable, and the centre of our planetary system. Plato was the reviver of the system of the immobility of the earth, and many philosophers followed his sentiment; among others was Claudius Ptolemy, the celebrated astronomer and mathematician of Pelusium in Egypt, already mentioned, who lived in the beginning of the second century of the Christian æra. It is, however, incredible that the true system of the world having been once discovered, the hypothesis by which the earth is supposed to be the centre of the celestial movements should have again prevailed; for though this hypothesis accords with appearances, and seems to agree at first with the simplicity of nature, yet it is impossible on that system to account for the celestial movements. Ptolemy, who has given the name to this system, endeavours to prove that the earth is truly immoveable as the centre of the universe; and he places the other planets round about her in the following order, beginning by those which he believes the next to the Earth; the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn, till he comes at length to the fixed stars. His principal reason for placing Mercury and Venus beneath the Sun, though they are often seen further from the Earth than from the Sun, was, without doubt, because the duration of their revolution was shorter than the apparent revolution of the Sun. When, however, astronomers had begun to observe the planets, they remarked that Mercury and Venus are sometimes nearer, and sometimes further, than we are from the Sun; and that Venus never departs from the Sun more than about 47 degrees and a half; and Mercury about 28 degrees and a half, and sometimes much less. But it is evident that if these two planets turned about the Earth, as they suppose the Sun himself turned, they would sometimes appear opposite to the Sun, or further from him than 180 degrees, which never happens. This is the reason why the Egyptians regarded these two planets as satellites of the Sun, and thought that they turned about him, their orbits being carried with this star in his revolutions about the Earth. They therefore supposed the Earth immoveable, as the centre of the system; and they supposed the other celestial bodies to turn round her: first, the Moon; secondly, the Sun, about which they made Mercury and Venus turn, without ever touching the Earth in their revolution, till they come to Mars, Jupiter, and to Saturn, the whole of their movements being determined by the fixed stars.

At the present day, when we know the immense distances which separate these stars, both of these systems become insupportable, because of the prodigious rapidity which they require in the movements of the celestial bodies: for if we take a view of these distances, it will be found necessary for these stars to go through the whole course of their orbits in about 24 hours, and that the Sun should run through, in a second of time, more than the space of 2500 leagues. Toward the year 1530, Copernicus, with a view of obviating the inconveniencies of the imaginary systems that preceded him, commenced at first by admitting the diurnal motion of the Earth, or her motion round her own axis; which rendered useless that prodigious celerity in the motions of the heavenly bodies, of which we have just spoken, and by these means simplified the system. This motion being once admitted, it was no violent step to admit a second motion of the Earth in the ecliptic. These two motions explain, with the utmost facility, the phenomena of the stations and motion of the planets, According to Copernicus, then, the Sun is the centre of our planetary system, and the planets turn about him in the order following; Mercury, Venus, the Earth, Mars, Ceres, Pallas, Juno, Vesta, and Jupiter, Saturn, the Herschel, at a distance from the Sun nearly as the numbers 4, 7, 10, 15, 28, 28, 32, *, 52, 95, 191. The Moon also he supposed to be carried round the Earth, in an orbit which goes along with the Earth in her annual motion round the Sun. In like manner about Jupiter, Saturn, and the Herschel, are the four satellites of the first, the seven satellites of the second, and the six satellites of the third. Although the celestial phenomena explain themselves with the greatest facility according to the system of Copernicus, and though observation and reason are equally favourable to it, yet he found in his time an able astronomer who rejected the evidence of his discoveries. Tycho Brahe, from the experiment that a stone thrown from a high tower fell at its feet, argued that the Earth must be without motion; never reflecting that the Earth, in that case, is like a vessel in full sail; where if a stone is thrown from the mast, it will fall at the foot of that mast, provided the motion of the vessel was neither accelerated nor retarded. Tycho Brahe, therefore, invented a system between that of Ptolemy and that of Copernicus. He supposed that the Earth was at rest, and that the other planets turn round the Sun, turning also with him round the Earth in

twenty-four hours. It was toward the end of the sixteenth century that he proposed his system. He placed the Earth immoveable as the centre, and made the Moon turn round her, the Sun also, and the fixed stars: the planets, *viz.* Mercury, Venus, Mars, Jupiter, and Saturn, turning round the Sun, in orbits which are carried with him in his revolution round the Earth.

Celestial Phenomena. Upon examining the heavens, the first and most obvious phenomenon that presents itself to observation, is the apparent diurnal motion of the sun, moon, and stars, or that by which they are seen to rise and set once in twenty-four hours.

If, to consider more attentively the circumstances of this diurnal motion, we place ourselves in an elevated situation, we shall perceive a circle terminating our view on all sides, by the apparent meeting of the earth and heavens. This circle is called the horizon: it divides the heavens into two parts; that which is above the horizon only is visible; and this appears to us like a concave hemisphere, which we call the sky, in which we see the heavenly bodies move. The sky is not a real substance; its blue colour is only owing to the refraction of the rays of light which pass through it.

On considering with attention for one or more nights the motions of the stars, we find each star describing a circle in about twenty-four hours. Those stars that appear northward describe smaller circles than those that are more to the south. If we look toward the south, we observe some stars just appearing above the horizon, grazing this circle, but not rising above it, and then vanishing; others a little further from the south, rise above the horizon, making a small arc, and then go down; while some again describe a larger arc, and take a longer time in setting. If we now turn to the north, we shall find that some just skim the horizon, mount to the top of the heavens, and then descend, and again touch the horizon, and mount without ever disappearing. Others, that are higher, describe complete circles in the sky, without coming to the horizon; and these circles diminish, till at last we arrive at a star that scarcely seems to move from the point where it is stationed, the rest wheeling round it.

It may be easily conceived, that as there is a hemisphere above, there is also another beneath, though invisible; and that, of course, the horizon is a great circle of the sphere, dividing the concave heavens into two parts, the visible above, and the invisible below. The general appearance, therefore, of the starry heavens, is that of a vast concave sphere turning round two fixed points diametrically opposite to each other; the one in the northern hemisphere visible to us; and the other in the southern hemisphere.

The fixed points round which this sphere is supposed to turn, are the poles, and a line drawn from one to the other is called the axis of the sphere; and round this line the heavens seem to turn every day.

To understand this more clearly, we must have recourse to a figure, or diagram. Let H O, see Astronomy, Plate XII. fig. 1, represent the circle of the horizon, seen edgewise, when it will appear as a straight line; let H P F O R Q be the complete sphere of the heavens, of which we shall suppose H P E O to be the visible hemisphere, and H Q R O the invisible hemisphere: then P will be the pole, or fixed point, among the stars visible to us, round which they all appear to turn, and R will be the opposite pole, or fixed point, in the sphere; a line from P to R will be the axis of the sphere. If through the centre of the sphere C, there is drawn a line Q E, it will represent the edge of a great circle, at equal distances from both poles, and at right angles to the axis, called the equator, because it divides the heavens into two equal parts.

If H O be the horizon, the highest point, or that immediately over our heads, as M, is called the zenith; and the opposite point in the sphere, or lowest point N, is called the nadir.

The rising and setting of the sun are the two most remarkable circumstances to be observed in the heavens. He rises in the east, mounts to the highest point in the arch which he describes, and descends in the west. The highest point to which he reaches, is naturally called the mid day point. If a great circle is traced through this point and the zenith, it is called the meridian of the place; and all the stars must cross this circle, or meridian, twice in the twenty-four hours; but those that go below the horizon are seen only to cross it once, because when they cross it a second time they are invisible.

Three great circles are now established in the heavens; the horizon, the equator, and the meridian. The first determines the rising and setting of the heavenly bodies; and also the altitude of any of them, at any time of their course. For this purpose we must suppose another great circle to pass through the star and the zenith; it will consequently be perpendicular to the horizon. This is called a vertical circle, and upon this circle we reckon the number of degrees which the star is distant from the horizon. The quadrant is an instrument for measuring the number of degrees of altitude which any body has.

The three great circles already mentioned form the basis of all observations upon the heavenly bodies, and to them all their situations must be referred. It is necessary, therefore, to determine the relative situations of these circles. If the polar star had been accurately at the pole of the heavens, nothing more would be necessary, in order to obtain the altitude of the pole, than to take the altitude of this star; but this star is situated two degrees distant from the pole; two degrees must therefore be added to this altitude, to find that of the pole.

The elevation of the pole being discovered, it is easy to find that of the equator. Thus, in the diagram, fig. I. H M O, or the visible part of the heavens, contains 180 degrees; but it is 90 degrees from the pole P, to E the equator. If we take away P E from the semicircle H M O, there remains 90 degrees for the other two arcs; or, in other words, the elevation of the pole and the equator, are together equal to 90 degrees; so that the one being known, and subtracted from 90 degrees, it will give the other; therefore, the elevation of the pole at any place, is the complement of the elevation of the equator, or what that elevation wants of 90 degrees. Hence it follows, that the elevation of the equator is equal to the distance from the pole to the zenith; for the elevation of the equator is the difference between that of the pole and 90 degrees: the same elevation subtracted from 90 degrees gives its distance from the zenith. A little attention will soon convince us that the sun does not always rise at the same point of the heavens. Thus, if we commence our observations on the sun, for instance in the beginning of March, we shall find him appear to rise more to the northward every day, to continue longer above the horizon,

and to be more vertical or higher at mid day. This continues till toward the end of June, when he moves backward in the same manner, and continues this retrograde motion till near the end of December, when he begins to move forward, and so on. It is from this change in the sun's place, and from his height being so much greater in summer than in winter, that the different length of the days and nights, and the vicissitudes of seasons, are owing. We cannot observe the sun's motion among the fixed stars, because he darkens the heavens by his splendour, and effaces the feeble light of those stars that are in his neighbourhood; but we can observe the instant of his coming to the meridian, and his meridional altitude; we can also compute what point of the starry heavens comes to the same meridian at the same time, and with the same altitude. The sun must be at that point of the starry heavens, thus discovered. Or we can observe that point in the heavens which comes to the meridian at midnight, with a declination as far from the equator on one side as the sun's is on the other side; and it is evident the sun must be in that part of the heavens which is diametrically opposite to this point. By either of these methods we may obtain a series of points in the heavens, through which the sun passes, forming a circle called the ecliptic. This circle has its name from the circumstance, that all the eclipses of the sun and moon are performed either actually in, or very near, the circumference of that circle.

The ecliptic, or annual path of the sun, differs in situation from the equator; for the sun rises above the equator in summer, and does not rise so high in winter. The points of the ecliptic where the sun is situated when he is most distant from the equator, are called solstitial points; and the distance between the equator and the ecliptic at the solstitial points, is called the obliquity of the ecliptic; this is found to be about twenty-three and a half degrees. A B, fig. 1. represents the ecliptic, inclined twenty-three and a half degrees to the equator E Q.

The equinoctial colure is the great circle which passes at right angles to the equator, through those two points of it that are intercepted by the ecliptic, called the equinoctial points. The solstitial colure is the other great circle at right angles to the equator, cutting it in the solstitial points. It passes through the poles of the ecliptic.

If smaller circles of the sphere are described touching the solstitial points, and at right angles to the axis, as A C, B D, they are tropics; of which that on the south side of the equator is called the tropic of Capricorn, and that on the north side of the equator the tropic of Cancer. The two polar circles F G, I K, are at the same distance from the two poles as the tropics are from the equator; that is, twenty-three and a half degrees.

It is necessary here to mention the difference between what is called the sensible and rational horizon. If we suppose that part of the surface of the earth on which we stand to be a plane, and to be extended every way till it reaches the heavens, this plane forms the sensible horizon. The rational horizon is a circle, the plane of which is parallel to the former, but passing through the centre of the earth. Though the globe of the earth appears so large to those who inhabit it, yet it is so small when compared with the immense sphere of the heavens, that the distance between the sensible and rational horizons is nothing in comparison with it.

The zodiac is a broad portion of the heavens, which stretches about eight degrees on each side of the ecliptic; it is divided into twelve parts, called signs; and each sign into thirty parts, called degrees. If we imagine a number of great circles of the sphere standing at right angles to the plane of the ecliptic, and consequently intersecting each other in its poles, these are called circles of celestial longitude, and they will divide the ecliptic into equal parts. Upon the ecliptic is reckoned the longitude of any fixed star, beginning to reckon at that point where the ecliptic and the equator intersect each other in the vernal equinox, called the first point of Aries; and the arch of any of the circles of celestial longitude, intercepted between a star and the ecliptic, is the latitude of that star. The equator is divided into degrees, but they are called degrees of right ascension, and from it to the poles the degrees of declination are reckoned upon the meridian of the place.

Having now described the principal lines and points on the celestial sphere, as generated by the apparent motions of the heavenly bodies, in which we have supposed what appears at first sight to be the case, *viz.* that the earth stands still while all the heavenly bodies revolve round it. This will make no difference with regard to these circles in the heavens; for it will be the same thing with respect to them, whether the earth is at rest, and the heavenly bodies move round it, or whether the latter remain still, and the earth, as we shall afterward see, moves round on its axis once every twenty-four hours.

Of the Solar System. If we examine the heavens in a clear night, we shall discover some stars which have brighter and steadier light than the rest; and if we continue to observe these for several nights, we shall find that they do not appear in the same place among the rest of the stars every night, but that they have motions peculiar to themselves. All the rest of the stars, rising and setting always exactly in the same places, are called fixed stars. Those wandering or moving stars, are called planets.

It is now fully proved, that these planets, with the earth which we inhabit, and also the moon, revolve round the sun, which is fixed in the centre of the system. There are two kinds of planets, primary and secondary. The first move round the sun, and respect him only as the centre of their motions. The secondary planets, called also satellites or moons, are smaller planets, revolving round the primary; while they, with the primary planet about which they move, are carried round the sun. The planets move round the sun at various distances, some being much nearer to him than our earth, and others being much further off.

Of these, our earth is accompanied by one moon, Jupiter has four moons, Saturn has seven, and the Herschel planet has six moons. None of these moons, except our own, can be seen without a good telescope. The other five planets do not appear to have any satellites or moons.

There are eleven primary planets, which are situated with respect to their distances from the sun as follows: Mercury ☿, Venus ♀, the Earth ⊕, Mars ♂, Ceres, Pallas, Juno, Vesta, Jupiter ♃, Saturn ♄, and the Herschel or Georgium Sidus ♅. See Plate II. Solar System.

All the planets move round the sun from east to west, and in the same direction do the moons revolve round their primaries; excepting those of the Herschel planet, which seem to move in a contrary direction. The paths in

which they move round the sun are called their orbits. These orbits are elliptical; but the eccentricity of the ellipses is so small, that they approach very nearly to circles. They perform their revolutions also in very different periods of time. The time of performing their revolutions is called their year.

TABLE OF THE SOLAR SYSTEM.

	Apparent mean diameters, as seen from the Earth.	Mean diameters in English miles.	Mean distances from the Sun in round numbers of miles.	Diurnal rotations, or round their own axes.	Time of revolving round the Sun.	Inclination of the orbits of the Ecliptic.	Inclination of the axes to the orbits.
The Sun,	32′.1″,5	813,246	———	25d. 14h. 8m.	——	——	82° 44 0″
Mercury,	10″	3,224	37,000,000	unknown.	83d. 23h. 16m.	7° 0′ 0″	unknown.

The planets are evidently opaque bodies, and they shine only by reflecting the light which they receive from the sun; for Mercury and Venus, when viewed by a telescope, often appear to be only partly illuminated, and have the appearance of our moon when she is horned, having the illumined part always turned toward us. From the appearance of the boundary of light and shadow upon their surfaces, we conclude that they are spherical; which is confirmed by most of them having been found to turn periodically on their axes.

Venus and Mercury being nearer to the sun than our earth, are called inferior planets; and all the rest, which are without the earth's orbit, are called superior planets. That the first go round the sun is certain, because they are seen sometimes passing between us and the sun, and sometimes they go behind it. That their orbits are within that of the Earth is evident, because they are never seen in opposition to the sun, that is, appearing to rise from the horizon when the sun is setting. On the contrary, the orbits of all the other planets surround that of the earth; for they sometimes are seen in opposition to the sun, and they never appear to be horned, but always nearly or quite full, though sometimes they appear a little gibbous, or somewhat deficient from full.

We mentioned above, that all the planets move round the sun in elliptical orbits. The sun is situated in one of the foci of each of them. That focus is called the lower focus. If we suppose the plane of the earth's orbit, which passes through the centre of the sun, to be extended in every direction, as far as the fixed stars, it will mark out among them a great circle, which is the ecliptic; and with this the situations of the orbits of all the other planets are compared.

The planes of the orbits of all the other planets must necessarily pass through the centre of the sun; but if extended as far as the fixed stars, they form circles different from one another, as also from the ecliptic; one part of each orbit being on the north, and the other on the south side of the ecliptic. The orbit therefore of each planet cuts the ecliptic in two opposite points, which are called the nodes of that particular planet, and different from the nodes of another planet. A line passing from one node of a planet to the opposite node, or the line in which the plane of the orbit cuts the ecliptic, is called the line of nodes. That node, where the planet passes from the south to the north side of the ecliptic, is called the ascending node, and the other is the descending node. The angle which the plane of a planet's orbit makes with the plane of the ecliptic, is called the inclination of that planet's orbit. Thus, Astronomy, Plate XII. fig. 2. where F represents the sun, the points A and B represent the nodes, and the line A B the line of nodes formed by the intersection of the planes of the orbits C and D. The angle E F G is the angle of inclination of the planes of the two orbits to each other. The distance of either focus from the centre of the orbit, is called its eccentricity.

The two points in a planet's orbit which are furthest and nearest to the body round which it moves, are called the apsides; the former of which is called the higher apsis, or aphelion; the latter is called the lower apsis or perihelion. The diameter which joins these two points, is called the line of the apsides. When the sun and moon are nearest to the earth, they are said to be in perigee. When at their greatest distance from the earth, they are said to be in apogee.

When a planet is situated so as to be between the sun and the earth, or so that the sun is between the earth and the planet, then that planet is said to be in conjunction with the sun. When the earth is between the sun and any planet, then that planet is said to be in opposition. It is evident that the two inferior planets must have two conjunctions with the sun; and the superior planets can have only one, because they can never come between the earth and the sun. When a planet comes directly between us and the sun, it appears to pass over the sun's disc, or surface, and this is called the transit of the planet. When a

planet moves from west to east, *viz.* according to the order of the signs, it is said to have direct motion, or to be in consequentia. Its retrograde motion, or motion in antecedentia, is when it appears to move from east to west, *viz.* contrary to the order of the signs.

The place that any planet appears to occupy in the celestial hemisphere, when seen by an observer supposed to be placed in the sun, is called its heliocentric place. The place it occupies when seen from the earth, is called its geocentric place.

The planets do not move with equal velocity in every part of their orbits, but they move faster when they are nearest to the sun, and slower in the remotest part of their orbits; and they all observe this remarkable law, that if a straight line is drawn from the planet to the sun, and this line is supposed to be carried along by the periodical motion of the planet, then the areas which are described by this right line and the path of the planet, are proportional to the times of the planet's motion. That is, the area described in two days, is double that which is described in one day, and a third part of that which is described in six days; though the arcs, or portions of the orbit described, are not in that ratio.

The planets being at different distances from the sun, perform their periodical revolutions in different times; but it has been found that the cubes of their mean distances are constantly as the squares of their periodical times, *viz.* of the times of their performing their periodical revolutions.

These two last propositions were discovered by Kepler, by observations on the planets: but sir Isaac Newton demonstrated, that it must have been so on the principle of gravitation, which formed the basis of his theory. This law of universal attraction, or gravitation, discovered by Newton, completely confirms the system of Copernicus, and accounts for all the phenomena which were inexplicable on any other theory.

The sun, as the largest body in our system, forms the centre of attraction, round which all the planets move; but it must not be considered as the only body endued with attractive power, for all the planets also have the property of attraction, and act upon each other, as well as upon the sun. The actual point, therefore, about which they move, will be the common centre of gravity of all the bodies which are included in our system; that is, the sun, with the primary and secondary planets. But because the bulk of the sun greatly exceeds that of all the planets put together, this point is in the body of the sun. The attraction of the planets on each other, also disturbs their motions, and causes some irregularities.

It is this mutual attraction between them and the sun, that prevents them from flying off from their orbits by the centrifugal force which is generated by their revolving in a curve; while the centrifugal force keeps them from falling into the sun by the force of gravity, as they would do if it were not for this motion impressed upon them. Thus these two powers balance each other, and preserve order and regularity in the system.

It is an established maxim in philosophy, that if, when a body is projected in a straight line, it is acted upon by another force, drawing it toward a centre, it will be made to describe a curve, which will be either a circle or an ellipsis, according to the proportion between the projectile and centripetal force. If a planet at B, fig. 3. gravitates or is attracted toward the sun S, so as to fall from B to y in the time that the projectile force would have carried it from B to X, it will describe the curve B Y, by the combined action of these two forces, in the same time that the projectile force singly would have carried it from B to X, or the gravitating power singly have caused it to descend from B to y; and these two forces being duly proportioned, the planet, obeying them both, will move in the circle B Y T V.

But if, whilst the projectile force would carry the planet from B to b, the sun's attraction should bring it down from B to 1, the gravitating power would then be too strong for the projectile force, and would cause the planet to describe the curve B C. When the planet comes to C, the gravitating power, which always increases as the square of the distance from the sun S diminishes, will be yet stronger for the projectile force, and by conspiring in some degree with it, will accelerate the planet's motion all the way from C to K, causing it to describe the arcs B C, C D, D E, E F, &c. all in equal times.

Having its motion thus accelerated, it thereby acquires so much centrifugal force, or tendency to fly off at K, in the line K k, as overcomes the sun's attraction; and the centrifugal force being too great to allow the planet to be brought nearer to the sun, or even to move round him in the circle k m n, &c. it goes off, and ascends in the curve K L M N, &c. its motion decreasing as gradually from K to B, as it increased from B to K; because the sun's attraction now acts against the planet's projectile motion, just as much as it acted with it before.

When the planet has got round to B, its projectile force is as much diminished from its mean state as it was augmented at K; and so the sun's attraction being more than sufficient to keep the planet from going off at B, it describes the same orbit over again, by virtue of the same forces or powers.

A double projectile force will always balance a quadruple power of gravity. Let the planet at B, have twice as great an impulse thence toward X, as it had before; that is, in the same length of time that it was projected from B to b, as in the last example, let it now be projected from B to c; and it will require four times as much gravity to retain it in its orbit; that is, it must fall as far from B to 4, in the time that the projectile force would carry it from B to c, otherwise it would not describe the curve B D, as is evident from the figure. But in as much time as the planet moves from B to C, in the higher part of its orbit, it moves from I to K, or from K to L, in the lower part of it; because from the joint action of these two forces, it must always describe equal areas in equal times throughout its annual course. These areas are represented by the triangles B S C, C S D, D S E, E S F, &c. whose contents are equal to one another from the properties of the ellipsis.

We have now given a general idea of the solar system, and shall next describe the bodies that compose it.

Of the Sun. The Sun is considered, from its constant emanation of heat and light, to be an immense globe of fire. When viewed through a telescope, several dark spots are visible on its surface, which are of various sizes and duration. From the motion of these spots, the Sun has been found to move round its axis in twenty-five days, which i

two days less than its apparent revolution, in consequence of the Earth's motion in its orbit in the same direction; and its axis is found to be inclined to the ecliptic, in an angle of about eighty-two degrees and a half.

Various opinions have been formed respecting these spots; they have been considered as opaque islands in the liquid igneous matter, and by some as pits or cavities in the body of the Sun. But from whatever cause they may arise, they evidently adhere to its surface: for if one of them appears upon the eastern limb or edge of the Sun's disc, it is seen to move thence toward the western edge in about thirteen days and a half, then the spot disappears, and in about the same time it is seen again upon the eastern edge, and so continues to go round, completing its apparent revolution in twenty-seven days, during one half of which time we see it on the disc of the Sun, and during the other half it disappears, which could not happen if the spots did not adhere to the Sun. The following particulars respecting the Sun are given by sir Isaac Newton.

1. That the density of the Sun's heat, which is proportional to his light, is seven times as great in Mercury as with us, and that water there would be all carried off in the shape of steam; for he found, by experiments with the thermometer, that a heat seven times greater than that of the Sun's beams in summer will serve to make water boil.

2. That the quantity of matter in the Sun is to that in Jupiter nearly as 1100 to 1, and that the distance of that planet from the Sun is in the same ratio to the Sun's semidiameter; consequently, that the centre of gravity of the Sun and Jupiter is nearly in the superficies of the Sun.

3. That the quantity of matter in the Sun is to that in Saturn as 2360 to 1, and that the distance of Saturn from the Sun is in a ratio but little less than that of the Sun's semidiameter. And hence the common centre of gravity of Saturn and the Sun is a little within the Sun.

4. By the same method of calculation it will be found, that the common centre of gravity of all the planets cannot be more than the length of the solar diameter distant from the centre of the Sun.

5. The Sun's diameter is equal to 100 diameters of the Earth, and therefore its magnitude must exceed that of the earth one million of times.

6. If 360 degrees, the whole ecliptic, is divided by the quantity of the solar year, it will give 59′ 8″ which therefore is the medium quantity of the sun's apparent daily motion; hence his horary motion is equal to 2′ 27″. By this method the tables of the Sun's mean motion are constructed as found in astronomical books.

Of the inferior planets. Mercury being the planet nearest to the Sun, and the least in magnitude, is very seldom visible. It never appears more than a few degrees from the Sun's disc, and is generally lost in the splendour of the solar beams. On this account, astronomers have had few opportunities of making accurate observations upon it; no spots have been observed upon it, consequently the time of its rotation on its axis is not known. Being an inferior planet it must show phases like the moon, Plate XII. fig. 7; and it never appears quite full to us. It is seen sometimes passing over the Sun's disc, which is called its transit.

Venus is the brightest and largest to appearance of all the planets, and is distinguished from the rest by her superiority of lustre. It is generally called the Morning or Evening Star, according as it precedes or follows the apparent course of the Sun. There have been spots observed on its disc, by different astronomers, changing their position with respect to one another. The time of its diurnal revolution about its axis is nearly 23h. 20m. Venus also appears with phases; and transits sometimes take place, which are of very great importance in astronomy.

The *elongation* of any planet is its apparent distance from the Sun.

An inferior planet is at its greatest elongation, when a line drawn from the Earth through the planet is a tangent to the orbit of the planet; when the planet is at M, Plate XII. fig. 4, being in conjunction with the Sun, it has no elongation; as it moves from M to V, its elongation increases till at V, when E V drawn from the earth to the orbit of the planet is a tangent to that orbit, its apparent place in the ecliptic is C, and its elongation is S C, which is the greatest it can have, for in passing from V to N it decreases, and at N it is nothing. From N to U it increases, and at U the elongation is again at the greatest. This will hold equally in elliptical as in circular orbits. If the orbits of the planets were circular, the distance of each from the Sun would be to the Earth's distance, as the Sun at its greatest elongation to the radius, that is, as V S to E S. By examining the figure it will be seen, that the inferior planets are never in opposition to the Sun, and are never in quadrature. For in opposition, the Earth is between the Sun and the planets, which can never happen when the orbit of the planet M G B is included within that of the Earth. They are never in quadrature, because the greatest angle of elongation is contained by S E and E V, and if the angle S E V was a right angle, E V would be a tangent at E the Earth's orbit: but it is a tangent, as has been seen, to an orbit less than that of the Earth; it therefore makes an angle with S E, less than a right angle. Hence the reason that the inferior planets never appear far from the Sun; and as the orbit of Mercury is included within that of Venus, the former must, when visible, always appear nearer to the Sun, than the latter. We may also observe that the apparent velocity of Venus is greatest at the times of conjunction. Since the plane of her orbit is oblique to the Earth, those parts of it which are viewed by a spectator directly, will appear longer than other equal parts viewed obliquely. Of course, the motions of the planet, if uniform, will appear unequal.

The time when an inferior planet will come again into a given situation with respect to the Sun and the Earth, may be thus found. Whilst Venus performs one revolution, the Earth, whose periodical time is longer than that of Venus, will not have completed its revolution. Before Venus and the Earth can be again in the inferior conjunction, Venus must, therefore, besides its entire revolution, describe an arc equal to that which the Earth has passed over: consequently, the number of degrees passed over by each, or their angular motions, in the same time, will be reciprocally as their periodical times; that is, as the periodical time of the Earth is to the periodical time of Venus, so is the angular motion of Venus, which is equal to four right angles added to the angular motion of the Earth between two inferior conjunctions, to the angular motion of the Earth in the same time; whence, El. V. 17. as the difference between the periodical times of the Earth and Venus, is to the periodical time of Venus, so are four right angles, or 360°, to the number of degrees over which the Earth passes in her orbit from one inferior conjunction to another. This is only true upon the sup-

position that the planets move in circular orbits, in which case the following general rule would apply to the finding the time from conjunction to conjunction, or from opposition to opposition, of any two planets. "Multiply their periodic times together, and divide the product by their difference, and you have the time sought." For let P = the periodic time of the earth, p = that of the planet, suppose an inferior, t = time required: then P : 1 day :: $360°$: $\frac{360°}{P}$, the angle described by the earth in one day: for the same reason $\frac{360°}{p}$ is the angle described by the planet in 1 day: hence $\frac{360°}{p} - \frac{360°}{P}$ is the daily angular velocity of the planet from the Earth. Now if they set out from conjunction, they will return into conjunction again, after the planet has gained $360°$: hence $\frac{360°}{\frac{360}{p} - \frac{360}{P}}$: $360°$ :: 1 day : $t = \frac{P\,p}{P-p}$. For a superior planet $t = \frac{p\,P}{p-P}$.

When the inferior planets are passing from their greatest elongation V. fig. 4. through N their superior conjunction, to their greatest elongation U, they appear to a spectator on the Earth to move from west to east; for when the planet is at G it will appear to have moved from C to H, and when at A and B it will appear to have passed from H through L to *a* and *b*; of course the motion of the planet is *direct*, or from west to east; but while it moves from U to V, its motion will appear to us retrograde or from east to west; for when it has passed from U to J and K, it will appear to have moved in the heavens from D through d to *b* and *a*, that is, from east to west. When the inferior planets are at their greatest elongation, they appear stationary; because when the planets are at U and V, the line drawn from E the Earth to the planet, is a tangent to the orbit, which so nearly coincides with a small arc of the curve, that a spectator at the Earth cannot distinguish the tangent from the curve, when the planet is at V and U, of course it will in those positions seem to be stationary.

When Venus or Mercury is in its superior conjunction, or at N, the whole enlightened hemisphere is toward the Earth, and its entire disc is visible: as it passes toward its inferior conjunction, its enlightened hemisphere turns by degrees, from the Earth, till at the inferior conjunction M, its enlightened part is wholly turned from the Earth, and the planet becomes invisible, unless it appears on the Sun's disc; it is then called a transit.

Of the Earth. The Earth which we inhabit is a globular body, as may be proved from a variety of circumstances, the chief of which we shall here enumerate. It is always observed by mariners, that as they sail from any high objects, such as mountains, steeples, &c. they first begin to lose sight of the lower part of those objects, and then gradually of the higher parts: also, persons on shore first discover the upper parts of the masts of approaching vessels. This could not be the case, if the Earth was a plane; but is very easily accounted for, on the supposition of its being a sphere, as will be easily understood by examining fig. 5. Plate XII. Various navigators have also sailed completely round the earth, by continuing in the same direction, at last coming to the same place from which they set out.

The Earth, however, is not a perfect sphere, but a spheroid, having its equatorial diameter longer than the polar diameter, or axis. It is consequently flattest at the poles, and more protuberant at the equator. The diameter at the equator is 7977 English miles; that at the poles is 7940 miles. The surface of the Earth is much diversified with mountains and vallies, land and water. The highest mountains in it, are the Andes in South America, some of which are about four miles in perpendicular altitude. About two thirds of the globe are covered with water.

In consequence of the Earth's being a globe, people standing upon opposite sides of it, must have their feet toward each other. When in this situation they are called *antipodes* to each other. Hence it appears that there is no real *up* or *down;* for what is up to one country, is down to another. It must seem strange to those who are ignorant of the shape of the earth, to suppose that, if we could bore a hole downward, deep enough, we should come to the other side of the world, where we should find a surface and sky like our own; yet if we reflect a moment, we shall perceive that this is perfectly true. As we are preserved in our situations by the power of attraction, which draws us toward the centre of the earth, we call that direction down, which tends to the centre, and the contrary.

We mentioned before, that the Earth has two motions; the one a diurnal motion, round its own axis, in twenty-four hours; the other an annual motion, round the Sun, in 365 days, 6 hours, 56 minutes, 4 seconds. It is the former which causes light and darkness, day and night; for when one side of the Earth is turned toward the Sun, it receives his rays, and is illuminated, causing day: on the contrary, when one side of the Earth is turned from the Sun, we are in darkness, and then we have night. By the diurnal revolution of the Earth round its own axis from west to east, the heavenly bodies appear to us to revolve in the same time from east to west. And since the Sun and fixed stars are bodies immensely larger than the Earth, and at almost inconceivably great distances from it, we see upon how much more simple principles the alternate succession of day and night is effected by the revolution of the earth about its axis, than by supposing the Earth fixed, and the Sun and stars whirled round it, with an indefinite velocity.

The natural days are not equal to one another: for a natural day is the time in which the Earth performs one revolution round its axis, and such a portion of the second revolution, as is equal to the space which the Sun has apparently travelled that day; but these spaces are unequal, therefore, the additional portion of the second revolution, will be sometimes greater and sometimes less, and consequently the times in which the natural days are completed will be unequal. Hence arises the difference between a sundial and a well regulated clock, as measures of time; the former measuring the length of the natural day, the latter dividing time into equal portions of twelve hours

each: the clock will be *before* the dial, when the natural day is more than twenty-four hours: and after it, when the natural day is less than twenty-four hours; and they will be together, only when the natural day is exactly twenty-four hours.

The *equation* of time is the difference between the mean length of the natural day, or twenty-four hours, and the length of any single day measured by the sun's apparent motion, or between *mean* and *apparent* time. And the hour of the day by apparent time being known, in order to determine what is then true time, the equation is to be added to apparent time, if the day by the clock is shorter than the day by the dial: and the equation is to be subtracted from the apparent time when the day by the clock is longer than the day by the sundial. If the natural day is twenty-four hours three minutes long, the day by the clock being twenty-four hours in length, it will be 12 by a good clock 3 minutes before it is 12 by the dial; in this case mean time precedes apparent.

The difference between mean and apparent time, depends upon two causes: 1. the obliquity of the ecliptic with respect to the equator: and, 2. the unequal motion of the earth in an elliptical orbit. The obliquity of the ecliptic to the equator would make the sun and clocks agree on four days of the year, *viz.* when the sun enters Aries, Cancer, Libra, and Capricorn. But the other cause which arises from his unequal motion in his orbit would make the sun and clocks agree only twice a year, that is, when he is in perigee, and apogee; consequently, when these two points fall in the beginnings of Cancer and Capricorn, or of Aries and Libra, they will concur in making the sun and clocks agree in those points. But the apogee, at present, is in the ninth degree of Cancer, and the perigee in the ninth degree of Capricorn; and, therefore, the sun and clocks cannot be equal at the beginnings of these signs, nor, indeed, at any time of the year, except when the swiftness and slowness of the equation resulting from one of the causes, just balances the slowness or swiftness arising from the other; which happens about the 15th of April, the 15th of June, the 31st of August, and the 24th of December; at all other times the sun is too fast or too slow for equal time by a certain number of minutes and seconds, which at the greatest is 16 minutes, 14 seconds, and happens about the first of November: every other day throughout the year having a certain quantity of this difference belonging to it, which, however, is not exactly the same every year, but only every fourth year, for which reason, it is necessary, where great accuracy is required, to have four tables of this equation, *viz.* one for each of the four years in the period of leap year. The following concise table, adapted to the second year after leap year, will always be found within about a minute of the truth, and therefore sufficiently accurate for common clocks and watches.

TABLE FOR THE EQUATION OF TIME.

Those columns that are marked +, show that the clock or watch is, or ought to be, before the sun; and those marked —, that it is slower. To regulate a clock or watch on the first of January, the moment the sundial is 12, the clock or watch must be put 4 minutes after. On the 13th of May, when the dial is 12, the clock to be right must want 4 minutes of that hour. See Ferguson's Astronomy, ch. 13. Phil. Trans. vol. 54.

Twilight is owing to the refraction of the rays of light by our atmosphere, through which they pass; and which, by bending them, occasions some to arrive at a part of the earth that could not receive any direct rays from the sun, or so as to bring him into sight, every clear day, before he rises in the horizon, and to keep him in view for some minutes after he is really set below it. The effect of this refraction is about six minutes every day at a mean rate.

From the same cause, the heavenly bodies appear higher than they really are, so that to bring the apparent altitudes to the true ones, the quantity of refraction must be subtracted. The higher they rise the less are the rays refracted, and when the heavenly bodies are in the zenith, they suffer no refraction, according to the principles of optics hereafter to be demonstrated. Tables of refractions have been calculated by various astronomers, as sir I. Newton, Mr. Thomas Simpson, Dr. Bradley, Mr. Mayer, &c. The following specimen is taken from Dr. Bradley's table, which is esteemed the most correct, and chiefly used by astronomers. For the method of calculating these tables, see Mr. Simpson's Dissert. p. 46, 4to. Gregory's Astron. Vol. I. Pa. 66, and Vince's Astron. Vol. I. 4to. ch. 7.

Dr. Keill, in his Lectures on Astronomy, observes, that it is entirely owing to the atmosphere that the heavens appear bright in the day time. For without it, only that part of the heavens would be luminous in which the sun is placed; and if we could live without air, and should turn our backs to the sun, the whole heavens would appear as dark as in the night. In this case also we should have no twilight, but a sudden transition from the brightest sunshine to dark night immediately upon the setting of the sun; which would be extremely inconvenient, if not fatal to the eyes of mortals. See Keill's Astron. Lect. xx.

The twilight is longest in a parallel sphere, and shortest in a right sphere: and in an oblique sphere, the nearer the sphere approaches to parallel, the longer is the twilight.

In a parallel sphere, the twilight will continue till the sun's declination toward the depressed pole is 18°: but in this sphere his declination is never more than 23½ degrees; whence the twilight will only cease, whilst the sun's declination is increasing from 18° to 23½ degrees, and decreasing again till in its decrease it becomes 18 degrees. The twilight is here caused by the annual motion of the earth. In a right sphere, the sun appears to be carried, by the daily motion of the earth, in circles perpendicular to the horizon; whence it is carried directly downward by the whole daily motion, and will arrive at 18 degrees below the horizon the soonest possible; whereas, in an oblique sphere, its path is oblique to the plane of the horizon, and therefore will be longer before it has descended 18 degrees below the horizon: and the difference of the time of twilight will increase with the degree of obliquity. As the sun sets more obliquely at some parts of the year than others, the twilight varies in its duration.

Of the Seasons. It is the annual motion of the earth round the sun, which occasions the diversity of seasons. To understand this, it must be remembered, that the axis of the earth is inclined to the plane of its orbit about 23½ degrees, and it keeps always parallel to itself; that is, it is always directed to the same point of the heavens.

The obliquity of the ecliptic is not permanent, but is perpetually diminishing, by the ecliptic approaching nearer to a parallelism with the equator, at the rate of about half a second in a year, or from 50 seconds to 55 seconds in a hundred years. The inclination at this time is rather less than 23 degrees, 28 minutes. The diminution of the obliquity of the ecliptic to the equator is owing to the action of the planets upon the earth, especially the planets Venus and Jupiter. The obliquity of the ecliptic is found by observing with great accuracy the meridian altitude of the sun's centre, on the days of the summer and winter solstice: then the difference of the two, will be the distance between the tropics; the half of which is the obliquity sought.

Let Fig. 6. Plate XII. represent the earth in different parts of its elliptic orbit.

In the spring, the circle which separates the light from the dark side of the globe, called the terminator, passes through the poles as appears in the position A. The earth then, in its diurnal rotation about its axis, has every part of its surface as long in light as in shade; therefore the days are equal to the nights all over the world, the sun being at that time vertical to the equatorial parts of the earth.

As the earth proceeds in its orbit, and comes into the position B, the sun becomes vertical to those parts of the earth under the tropic, and the inhabitants of the northern hemisphere will enjoy summer, on account of the solar rays falling more perpendicularly upon them; they will also have their days longer than their nights, in propor-

tionas they are more distant from the equator; and those within the polar circle, as will be perceived by the figure, will have constant daylight. At the same time, the inhabitants of the southern hemisphere have winter, their days being shorter than their nights, in proportion as they are further from the equator; and the inhabitants of the polar regions will have constant night.

The earth then continues its course to the position C, when the terminator again passes through the poles, and the days and nights are equal.

After this, the earth advances to the position D, at which time the inhabitants of the northern hemisphere have winter, and their days are shorter than their nights.

The positions B and D, are the solstitial points; and A and C, the equinoctial points; they are not equidistant from each other, because the sun is not in the centre, but in the focus of the ellipsis. In summer, when the earth is at B, the sun is further from it than in the winter, when the earth is at D; and in fact, the diameter of the sun appears longer in winter than in summer. The difference of heat is not owing to the sun's being nearer to us, or more remote, but to the degree of obliquity with which its rays strike any part of the earth.

Of the Moon. The moon is, next to the sun, the most remarkable of the celestial objects. Its form is spherical like that of the earth, round which it revolves, and by which it is carried round the sun. Its orbit is also elliptical, having the earth in one of the foci of the ellipsis. The moon always keeps the same side toward the earth, showing only at one time a little more of one side, and at another time a little more of the other. Hence as the moon revolves about its axis, its periodical time must be equal to that of its revolution in its orbit round the earth. This is found to be the case with the fifth satellite of Saturn as it regards its primary. And though the year is of the same absolute length, both to the earth and moon, yet the number of days in each is very different: the former having $365\frac{1}{4}$ natural days in its year, but the latter has only about $12\frac{7}{8}$, every day and night in the moon being as long as $29\frac{1}{2}$ on the earth.

The face of the moon, as seen through a telescope, appears diversified with hills and vallies. This is proved by viewing her at any other time than when she is full; for then there is no regular line bounding light and darkness; but the edge or border of the moon appears jagged; and even in the dark part near the borders of the lucid surface, there are seen some small spaces enlightened by the sun's beams.

Besides, it is moreover evident, that the spots in the moon taken for mountains and vallies, are really such from their shadows. For in all situations of the moon, the elevated parts are constantly found to cast a triangular shadow in a direction from the sun; and the cavities are always dark on the side next to the sun, and illuminated on the opposite side. Hence astronomers are enabled to find the height of the lunar mountains. Dr. Keill, in his Astronomical Lectures, has calculated the height of St. Catherine's hill to be nine miles. Since, however, the loftiest mountains upon the earth are but about three miles in height, it has been long considered as very improbable that those of a planet so much inferior in size to the earth should exceed in such vast proportion the highest of our mountains.

By the observations of Dr. Herschel, made in November, 1779, and the four following months, we learn, that the altitude of the lunar mountains has been very much exaggerated. His observations were made with great caution, by means of a Newtonian reflector, six feet eight inches long, and with a magnifying power of 222 times, determined by experiment; and the method which he made use of to ascertain the altitude of those mountains which, during that time, he had an opportunity of examining, seems liable to no objection. The rock situated near Lacus Niger, was found to be about one mile in height, but none of the other mountains which he measured proved to be more than half that altitude; and Dr. Herschel concludes, that with a very few exceptions, the generality of the lunar mountains do not exceed half a mile in their perpendicular elevation. See Keill's Astron. Lect. x. Phil. Trans. Vol. LXX.

To Dr. Herschel also we are indebted for an account of several burning volcanoes, which he saw at different times in the moon. In the 77th vol. of the Phil. Trans. he says, "April 19, 10 hours, 36 minutes, sidereal time. I perceive three volcanoes in different places of the dark part of the new moon. Two of them are nearly extinct; or, otherwise, in a state of going to break out, which perhaps may be decided next lunation. The third shows an actual eruption of fire, or luminous matter." On the next night Dr. Herschel saw the volcano burn with greater violence than on the preceding evening. He considered the eruption to resemble a small piece of burning charcoal when it is covered by a thin coat of white ashes, which frequently adhere to it, when it has been some time ignited; and it had a degree of brightness about as strong as that with which such a coal would be seen to glow in faint daylight. It is generally admitted that the moon has an atmosphere.

The moon is seen by means of the light which comes to it from the sun being reflected from it. Its changes or phases depend upon its situation relatively to the earth and the sun. When the moon is in opposition to the sun at A, fig. 7. Plate XII. the enlightened side is turned toward the earth, as *a*, and it appears full. When the moon is in conjunction at E with the sun, its dark side is turned toward us, and it is invisible, as at *e*. As it proceeds in its orbit, as at F, a small part of the enlightened side is seen, and then we have what is called a new moon; and we continue to see more and more of the enlightened side, as the moon approaches at G and H, to the state of opposition or full moon. The waning or decreasing of the moon takes place in the same manner, but in a contrary order. The earth must perform the same office to the moon that the moon does to us; and it will appear to the inhabitants of the moon, if there be any, like a very magnificent moon, being to them about thirteen times as large as the moon to us, and it will also have the same changes or phases. Hence it is evident, that one half of the moon is never in darkness, the earth constantly affording it a strong light, during the absence of the sun; but the other half has a fortnight's light and darkness by turns.

When the moon is near the first of Aries, and moving toward the tropic of Cancer, the time of its rising will vary but little for several days together. If the moon were to move in the equator, its motion in its orbit, by which it describes a revolution, in respect of the sun, in 29 days, 12 hours, would carry it every day eastward from the sun about 12 degrees 11 minutes, whence its time of rising would vary daily about 50 minutes. But, because the moon's orbit is oblique to the equator, nearly coinciding with the ecliptic, different parts of it make dif-

ferent angles with the horizon, as they rise or set; those parts which rise with the smallest angles setting with the greatest, and the reverse. Now the less this angle is, the greater portion of the orbit rises in the same time. Consequently, when the moon is in those parts which rise or set with the smallest angles, it rises or sets with the least difference of time, and the reverse. But in northern latitudes, the smallest angle of the ecliptic and horizon is made when Aries rises and Libra sets, and the greatest when Libra rises and Aries sets; and therefore, when the moon rises in Aries, it rises with the least difference of time. Now the moon is in conjunction in or near Aries, when the sun is in or near Libra, that is, in the autumnal months; when, the moon rising in Aries, whilst the sun is setting in Libra, the time of its rising is observed to vary only two hours in six days in the latitude of London. This is called the harvest moon.

This circumstance takes place every month; but as it does not happen at the time of full moon, there is no notice taken of it. When the moon's right ascension is equal to six signs, that is, when she is in or about the beginning of Libra, there is the greatest difference of the times of rising, *viz.* about an hour and 15 minutes. Those signs which rise with the least angle set with the greatest, and the contrary; therefore, when there is the least difference in the times of rising, there is the greatest in setting, and vice versa.

The following table shows the daily mean difference of the moon's rising and setting, on the parallel of London, for 28 days; in which time the moon finishes her period round the ecliptic, and gets nine degrees into the same sign from the beginning of which she set out.

The Moon's motion is subject to many irregularities, on account of the inclination of its orbit to the plane of the ecliptic, and the attraction of the Sun and the other planets.

Of the superior planets.

Mars is not so bright as Venus, nor even as Jupiter, though nearer to the sun. Its colour is a little reddish. Some spots have been observed upon its surface, from which its rotation round its axis, and the inclination of its axis to the plane of its orbit, have been determined.

The following particulars respecting Mars are given by Dr. Herschel, after long and accurate observations.

The axis of Mars is inclined to the ecliptic 59° 42.

The node of the axis is in 17° 47′ of Pisces.

The obliquity of the ecliptic on the globe of Mars is 28° 42′.

The point Aries on the Martial ecliptic answers to our 19° 28′ of Sagittarius.

The figure of Mars is that of an oblate spheroid, whose equatorial diameter is to the polar one as 1355 to 1272, or as 16 to 15 nearly.

The equatorial diameter of Mars, reduced to the mean distance of the earth from the Sun, is 9″ 8‴.

And that planet has a considerable but moderate atmosphere; so that its inhabitants, probably, enjoy a situation, in many respects, similar to ours.

Phil. Trans. Vol. lxxiv. Part 2.

Ceres Ferdinandea is a very small planet, situated next without Mars: it was discovered on the first day of the present century by Mr. Piazzi, an Italian astronomer.

Pallas is another very small planet, discovered by Dr. Olbers of Bremen, on the 28th of March, 1802. Juno is likewise a very small planet, discovered by M. Harding, as he was engaged at Lilienthal, in examining the catalogue of the stars published by M. Lalande. This planet and the two former ones, Dr. Herschel proposes to call asteroides, because they are so much smaller than any of the other planets.

Juno is the twelfth planet discovered within these few years. Dr. Herschel discovered the planet that goes by his own name, March 18, 1781. In January 1787 he perceived that this planet had two satellites, and some time after he discovered four others belonging to his planet. In the autumn of 1789 he observed two new satellites belonging to Saturn. The Ceres was discovered in 1801; the Pallas in 1802; and the Juno in 1804.

Jupiter is the brightest planet next to Venus. When viewed by a telescope, several belts are observed across its disc, parallel to its equator: these belts are variable, and have been supposed to be ranges of clouds in the atmosphere of the planet. They are sometimes of different breadths, and sometimes nearly of the same breadth. Large spots have been seen in these belts; and when one of them vanishes, the contiguous spots disappear with it. Dr. Herschel has paid attention to the rotation of these spots, and has found that the rotation of the same spot diminished; thus in February 1778 one revolved in nine hours fifty-five minutes and twenty seconds, but the same spot in April revolved in nine hours fifty-one minutes and thirty-five seconds. This he observes is agreeable to the theory of equinoctial winds, as it may be some time before the spot can acquire the velocity of the wind; and if Jupiter's spots should be observed in different parts of its

year to be accelerated and retarded, it would almost amount to a demonstration of its monsoons, and their periodical changes. The ecliptic and equator of Jupiter are nearly parallel to each other, that is, the axis of the planet is nearly perpendicular to its orbit, and on that account its inhabitants experience no sensible change of seasons. This is a wise provision, for if the axis of Jupiter were inclined any considerable number of degrees, just so many degrees round each pole would, by turns, be almost six years in darkness. Jupiter is surrounded by four moons of different sizes, which move about it in different times. These moons are sometimes eclipsed by the shadow of Jupiter falling upon them. The eclipses have been found of great use in determining the longitudes of places on the earth.

Saturn can hardly be seen by the naked eye. When examined by a telescope, it exhibits a very remarkable appearance. It is surrounded by a thin, flat, broad luminous ring, which surrounds the body of the planet, but does not touch it. This ring casts a strong shadow upon the planet; and appears to be divided into two, by a distinct line in the middle of its breadth. This ring is circular, but appears elliptical from its being viewed obliquely. Besides this ring, Saturn has seven moons of different sizes; and its body is surrounded also by belts, like those of Jupiter.

The Herschel, with its six satellites, have been entirely discovered by Dr. Herschel. It cannot be seen without a telescope, but it does not require a powerful one. The satellites cannot be seen without the most powerful telescopes.

Having given a brief account of the Sun and planets, we shall show by what means we can ascertain their apparent and real diameters.

On the apparent and real diameters of the Sun and Planets. It is obvious from the principles of optics, that the determination of the real diameters of the heavenly bodies will depend conjointly on a knowledge of their apparent diameters, and their real distances from the earth. For, suppose A P B, Plate XII. fig. 8. a section of such body made by a plane passing through the place O of the eye, and the centre C of the body: then A O B will be the angle, which will measure the apparent diameter of the body; this being known, A O C, its half, will be known. And A O being a tangent to the surface, the angle C A O will be a right angle; whence, cosine A O C: sine A O C :: A O : A C, the semidiameter of the body. Now A C or O C, may be found by observation; or, when the body is in opposition or conjunction with the Sun, by taking the difference or sum of its distance from the Sun, and the earth's distance from that luminary, according to the respective cases; taking care to attend to the different operations required for a superior and inferior planet. And as to the apparent diameters, it may be worth while to point out a few methods of ascertaining them.

The Sun's vertical or perpendicular diameter may be found by two observers taking, the one the height of the upper edge of the disc, the other that of the lower, at the same instant. This is most conveniently done when the Sun is at or near the meridian; because there is then no sensible change in his altitude during the space of two or three minutes. The height of each edge must be corrected, by allowing for parallax and refraction; and the apparent diameter will be equal to the difference of the corrected altitudes of the upper and lower edge. This method is very simple, and gives the apparent diameter with exactness proportional to the accuracy of the instruments made use of.

Another method of determining the Sun's apparent diameter, is to observe by a good clock the time in which the sun's disc passes over the plane of the meridian, or some other hour circle. At, or very near, one of the equinoxes, when the sun's apparent diurnal motion is in the equator, or a parallel very near it, say, as the time between the Sun's leaving the meridian and returning to it again : 360° :: the time in which he passes over the meridian : his apparent semidiameter. At any other time of the year, when the Sun is in a parallel at some distance from the equator, his diameter measures a greater number of minutes and seconds in that parallel, than it would do in a great circle, and takes up proportionally more time in passing over the meridian; we may then use this analogy, as radius : cosine of the Sun's declination :: the time in which the Sun passes the meridian, converted into motion, at the rate of four minutes in time to 1° : the arc of the great circle which measures the Sun's apparent horizontal diameter. This method may be easily put in practice by two observers; or indeed by one, if he have an half second pendulum placed near enough for him to hear the beats of it, whilst he observes the transit. But the diameters of the planets are best taken by the micrometer, an instrument so contrived that two parallel wires being placed in the focus of a telescope, one fixed and the other moveable, or both moveable, they may be made to approach or recede one from the other till they appear to touch exactly two opposite points in the disc of the planet, and then the index shows the apparent diameter in minutes and seconds. The apparent diameters of the planets when at about their respective mean distances from the earth, are as we have seen: Mercury, 10″; Venus, 58″; Mars, 27;″ Jupiter, 39″; Saturn, 18″; Georgium Sidus, 3″ 54‴. And from these apparent diameters, and the respective distances from the earth, the diameters of the Sun and planets have been determined in English miles as here stated: Mercury, 3224; Venus, 7867; Mars, 4189; Jupiter, 89170; Saturn, 79042; the Herschel, 35112; the Sun, 883246. Observations upon the planets Herschel, Saturn, Jupiter, and Mars, prove that there is a sensible difference between their equatorial and polar diameters; and it is probable that there is a like difference between the diameters of the other planets, but this has not yet been determined by observation.

Since the apparent diameters of distant bodies vary inversely as their distances, we may, having the distances from the earth at which the respective planets subtended the above angles, and knowing their mean distances from the Sun, find the mean apparent diameters of all the planets, as seen from the Sun; they have been thus given: Mercury, 20″; Venus, 30″; Earth, 17″; Mars 10″; Jupiter, 37″; Saturn, 16″; Georgium Sidus, 4″.

To measure the quantity of matter in distant bodies appears a problem of insuperable difficulty: but this has been effected to a considerable degree, by the principles of the Newtonian philosophy. Since the quantity of matter in a globe is proportional to the mean density multiplied into the cube of the diameter, and the diameters of

the planets are known, the mean densities are all that are required for the solution of the problem. Now, in homogeneous, unequal, spherical bodies, the gravities on their surfaces are as their diameters, when the densities are equal; or the gravities are as the densities, when the bulks are equal: therefore, in spheres of unequal magnitude and density, the gravity is in the compound ratio of the diameters and densities; or the densities are as the gravities divided by the diameters. But the diameters are known, and the gravities at the surface are nearly found, either by means of the revolutions of the satellites, or by calculations deduced from the effects the planets are found to produce upon each other; consequently the relation of the densities becomes known. The mean density of the earth was calculated by Dr. Hutton, from observations made by Dr. Maskelyne at the mountain Schehallien; he made it to that of water as 9 to 2, and to common stone, as 9 to 5, on the supposition that the hill is only of the density of common stone. He also states the mean densities of the Sun and planets to that of water, thus: Sun, $1\frac{2}{15}$; Mercury, $9\frac{1}{6}$; Venus, $5\frac{11}{15}$; Earth, $4\frac{1}{2}$; Mars, $3\frac{2}{7}$; Jupiter, $1\frac{1}{24}$; Saturn, $0\frac{3}{32}$; and the Herschel $0\frac{99}{100}$. These densities are such as the bodies would have if they were homogeneal; and may be admitted as a fair estimate of the whole, although the density of each planet may vary considerably at different distances from the surface. From the densities, as thus estimated, and the known diameters, we may readily find the proportions of the quantities of matter; they are as under: the Sun, 333928; Mercury, 1654; Venus, ·8899; the Earth, 1; Mars, ·0875; Jupiter, 312·1; Saturn, 97·76; Georgium Sidus, 16·84.

Of the Satellites.

We have observed that Jupiter, Saturn, and the Herschel planet, are attended by satellites; of which Jupiter has four, Saturn seven, and the Herschel six. In order to arrive at certainty concerning the laws of these bodies, it is necessary to consider facts; we therefore briefly describe the chief phenomena. 1. These satellites are sometimes to the eastward, sometimes to the westward, of their respective planets, moving successively from one side to the other: each at its greatest excursion, as observed from the earth, is nearly as far distant from the one side as it was from the other, and is found on the same side again in much about the same interval of time; from which it is inferred that the orbits of the satellites are curves returning into themselves. 2. All the satellites, except those of the Herschel, in going from the western excursion to the eastern, are often hid by the planet's disc, and consequently pass behind it: sometimes one or other of them passes above or below, but never on, the planet's disc. On the contrary, in going from the eastern excursion to the western, those which passed behind, now pass over the disc; and those which passed above, now pass below, and reciprocally; which proves that they move with the primary as their centre. 3. The paths of the satellites being reduced to their respective planet's centre, sometimes appear in a right line passing through that centre, and inclined in a certain direction to its orbit. Afterward, they change more and more into ellipses, during one quarter of the planet's annual revolution; and all the superior conjunctions are then made above the planet's centre, and the inferior conjunctions below it: during a second quarter of the planet's revolution, these ellipses become narrower, the satellites are nearer the centre in their conjunctions, and at the end of a second quarter of the revolution, all the ellipses are again become right lines with equal inclination, but in a contrary direction. In the third quarter of the revolution, they are formed anew into ellipses, the superior conjunctions are made below the centre, and the inferior ones above; lastly, in the fourth quarter of the revolution, when the planet is returning to the same point of its orbit, these ellipses again decrease in breadth, and all return to the first state. 4. The times of the superior and inferior conjunctions of the satellites being compared, their intervals are nearly equal to their semirevolution.

Since, then, the satellites uniformly describe orbits nearly circular or elliptical, with their respective primary at their centre or focus, they are probably moved by a force of the same nature with that which moves their planets round the Sun; that is, they revolve about their primaries in consequence of a central force, and of a constant impulsive force: if so, which indeed observations render certain, they must follow Kepler's two rules, namely, 1. the satellites must describe areas of their orbits proportional to the times; 2. their mean distances from the centres of their respective primaries, must be as the cube roots of the squares of the times of their revolutions.

The time of a synodic revolution of a satellite may be found in the following manner: Observe, when the primary planet is in opposition, the passage of a satellite over its body; and mark the time when it is half way between the two opposite edges of the planet's disc, for then it will be nearly in conjunction with the centre of the planet, and also in conjunction with the Sun. After a long space of time, observe again when the primary planet is in opposition, and the secondary in conjunction with its centre; and divide the intervening space of time between the two observations, by the number of conjunctions of the Sun in that space, the quotient is the time of a synodic revolution. Or, the same thing may be found by means of the eclipses of the satellite: Observe when the satellite enters the shadow of its primary, called its immersion; or when it comes out of the shadow, called its emersion; and after a very long interval of time, when an eclipse happens as nearly as possible in the same situation both with respect to the node and to the place of the primary planet, again mark the time of the emersion or immersion, which ever was used in the former observation; and from the interval of these times, and the number of eclipses in that interval, the mean time of a synodic revolution will be obtained by division.

To determine the time of a periodic revolution, it must be considered, that in the return of a satellite to its mean conjunction, it describes a revolution in its orbit, together with the main angle m, described by the primary planet in that time: hence this analogy, as $360° + m$: 360:: time of a synodic revolution : the time of a periodic revolution.

The distance of a satellite from its primary may be easily found by means of its greatest elongation, as seen from the earth, in the following manner: let S, Plate XIII. fig. 9, represent the Sun, E the Earth, P any planet, one of its satellites at A, and the angle of elongation P E A a

maximum; then the distances P E and E S are known from the theory of the planet, and the time of observation; and since the angle P E A is known in the right angled triangle A E P, also the side P E, the side A P is readily obtained. After the same manner, when the earth and planet are in any other situations, e, p, and the satellite at a at its greatest elongation, find $e\ p$ by the theory of the earth and planet, and the given time, whence from the angle of elongation $p\ e\ a$, determine the distance $p\ a$. Make a series of such observations at all suitable opportunities, and calculate $a\ p$ or A P from each of them; for thus we may ascertain the greatest and least distance of the satellite from its primary, and half the difference of these will give the eccentricity of the orbit. These elements, if not determined accurately, may be corrected by subsequent observations.

The distances of a satellite from the centre of its primary may also be found, by measuring with a micrometer, at the time of the satellite's greatest elongation, its distance from the centre of the planet, also the semidiameter of the planet: for then the distance is known in terms of that semidiameter. Or, if the planet and satellite cannot at once be brought into the field of view of a telescope, which may sometimes happen, the distance of the satellite may be measured, at its greatest elongation, by observing the time of the passage of the planet's disc over a wire adjusted as an hour circle in the field of a telescope; and comparing it with the interval between the passage of the planet's centre, and that of the satellite. To give this method the greatest degree of accuracy, the observations should be repeated so long as the interval from the passages of the planet to that of the satellite continues increasing; for when it begins to decrease, the satellite will have passed its greatest elongation. The methods given in this article may also be applied to the determination of the distances when in the apsides, the eccentricity, and the greatest equation, by means of a long series of observations.

Or, when the periodic times of all the satellites of a planet are known, and the mean distance of one of them; the mean distances of the others may be found from the proportion between the squares of the periodic times, and the cubes of the distances. And, on the contrary, if the relative distances of all the satellites from their primary be known, and the periodic time of one of them, the periodic times of the others may be found by the same proportion.

The eclipses of the satellites are of considerable importance to astronomy and geography; it therefore becomes requisite to explain them. To this end, let S, fig. 10, be the Sun; E e the orbit of the Earth; P the place of the planet; $v\ s\ o$ the orbit of a satellite; then, it is evident, that whenever the satellite, in its orbit, passes through the shadow of the primary, its light is obscured, and it becomes eclipsed. The duration of the eclipse will depend upon the obliquity of the satellite's orbit to that of the planet, and the distance of the satellite from the node: for, fig. 11. a less proportion $m\ n$ of the inclined orbit will pass through the shadow O I $m\ n$, than if the orbit coincided with O N; and in the nodes the satellite is both in its own orbit, and that of the planet, and $n\ m$ becomes equal to O I. Now, fig. 10, when the earth is at E before the opposition of the planet, the spectator will see the immersion at i, and in some particular instances, the emersion at o also: when the earth is at e after opposition, an observer will see the emersion at o; but whether he sees the immersion, will depend upon the position of the earth with respect to the plane of the planet's orbit. When the earth is at E, the conjunction of the satellite happens later at the earth than at the Sun; but when it is at e, the conjunction occurs later at the Sun than at the earth. If the earth be at e, and the satellite at v, it cannot be seen by an observer at e, because the body of the planet intervenes; this is not an eclipse but an occultation. In order to find the diameter of the planet's shadow at the distance of any of the satellites, let the time of an eclipse, that is, the time occupied from the immersion to the emersion, be observed when the satellite is in one of its nodes; for then the satellite passes through the centre of the shadow, and the eclipse is called central: then use this analogy. As the time of a synodic revolution of the satellite : the duration of the eclipse :: 360° : the diameter of the shadow, in degrees of the satellite's orbit. But should it so happen that both the immersion and emersion cannot be seen when the satellites are in the nodes, which is always the case with the first and second of Jupiter's satellites, then it is usual to compare the immersion some days before the opposition of the planet, with the emersions some days after; and hence, knowing how many synodic revolutions have been made in the intervening time, the time of the transit through the shadow, and consequently the corresponding measure in degrees, become known.

The eclipses of the satellites afford us a manifest proof of the velocity of light. For, if the motion of light were infinite, or if it came to us from immense distances in an instant, it is evident we should see the commencement of an eclipse of a satellite, at the same moment, whatever distance we might be from it; but, on the contrary, if light move progressively, then it is equally evident, that the further we are from a planet, the later it will be before we perceive the beginning of an eclipse of one of its satellites, because the light will occupy a longer time in travelling to us. M. Roemer was the first who deduced from actual observations, the real velocity of light: he found, and it has since been confirmed by repeated experiments, that when the earth is exactly between Jupiter and the Sun, his satellites are seen eclipsed about $8\frac{1}{4}$ minutes sooner than they would be according to the tables; but that when the earth is at its greatest distance from Jupiter, these eclipses happen about $8\frac{1}{4}$ minutes later than the tables predict them. Hence it follows that light takes up about $16\frac{1}{2}$ minutes of time in passing over the diameter of the earth's orbit, which is, at a mean, 190 millions of miles; this is very nearly at the astonishing rate of 200,000 miles in a second. Dr. Bradley found very nearly the same velocity from observations on the fixed stars. Hence also it appears, that in determining the time of an eclipse of a satellite as seen from the earth, an allowance must be made, corresponding with the different distances of the earth and planet; this allowance is called the equation of light.

The satellites of Jupiter, Saturn, and Herschel, are subject to changes in their orbits, with respect to the situation of the apsides and nodes, the inclination of their orbits, their eccentricity, &c. similar to those of the moon, and from similar causes. But in many instances they

prevail to a greater degree, in consequence of the disturbing forces of the satellites upon each other; hence, therefore, a frequent revision of the tables is necessary.

The satellites of Jupiter, being situated nearer to the earth than those of any other planet, and being of very considerable importance in astronomy and navigation, have been more regularly and carefully observed than the other satellites; in consequence of which the elements of their orbits are determined with greater precision than those of the other satellites. The chief of these elements, as given by M. de Lalande, are exhibited in the following table.

SATELLITES OF JUPITER.

Of Eclipses.

The eclipses of the Sun and Moon are phenomena that command the attention even of the vulgar; who have always retained a superstitious veneration for the science of astronomy, chiefly on account of the means it affords of foretelling events of this nature. And though in reality the knowledge required in calculating an eclipse does not essentially differ from that employed in determining the time of the rising and setting of the Sun or Moon, yet there is no doubt that a more particular attention to this subject will be acceptable to the reader.

As the shadows of the Moon and Earth are the causes of eclipses, it will be necessary first to determine the figure of those shadows. Because the Sun, the Earth, and the Moon are spherical bodies, it follows that the shadows of the two latter must be either conical or cylindrical; that is to say, fig. 12, Plate XIII. if the Sun I K be less than the Earth C D, the shadow of the latter will be part of a cone, whose section is terminated by the lines C E, D F, and whose base is indefinitely distant: or, if the Sun A B be equal to the Earth C D, the shadow will be a cylinder between the lines C G, D H, whose base is indefinitely distant. In either case the shadows of the Earth must occasionally fall upon and eclipse the superior planets, when in opposition to the Sun. But this never happens; and therefore the Sun is neither less than, nor equal to, the Earth, but greater. We know moreover, from the Sun's parallax, that it is much greater than the Earth; because the Sun's diameter seen from the Earth is about 32 minutes, whereas the Earth's diameter seen from the Sun is only about 17 seconds, a quantity that may be regarded as insensible or inconsiderable in many observations. And since the Sun exceeds the Earth in so high a proportion, it must of necessity be yet greater with regard to the Moon, because this last is less than the Earth. Let A B, fig. 13, represent the Sun greater than the Earth C D. The rays of light A C, B D, passing from the extreme edges of the Sun, and in contact with the Earth on the same side, will afterward meet or cross in the point K. No part of the Sun's light will appear within the cone C K D; which is therefore the shadow in which an observer, being placed, would be totally deprived of the Sun. But there will be a partial shadow or penumbra between those rays A D M, B C L, that pass from the extreme edges of the Sun, and touch the opposite extremes of the Earth; that is to say, an observer between the lines C L and D M, but without the dark cone, C K D, will see only a part of the Sun, the rest being hidden by the interposition of the Earth: the quantity of the Sun thus obscured will be greater, and the penumbra darker, the nearer the observer is placed to the cone C K D. Lastly, if the observer be situated beyond the vertex of the dark shadow K, between the lines K N, K O, formed by the continuation of the extreme rays, he will behold the exterior parts of the Sun forming a lucid ring, environing the Earth on all sides.

The angle C K D, at the vertex of the Earth's shadow, is, by Euclid I. 32, equal to the difference between the diameter of the Sun seen from the Earth, or angle A C B, and the diameter of the Earth seen from the Sun, or angle C B D. Or, if the earth's apparent diameter from the

Sun be rejected as inconsiderable, the angle of the shadow will be equal to the Sun's apparent diameter.

The angle C I D, at the vertex of the penumbra, is equal to the sum of the diameter of the Sun seen from the Earth, or angle A C B, and the diameter of the Earth seen from the Sun, or angle C A D: or, if the Earth's apparent diameter from the Sun be rejected as inconsiderable, the angle of the penumbra is equal to the Sun's apparent diameter. Every thing that has been here shown respecting the shadows of the Earth, is true in like circumstances of the Moon.

To apply these observations to the facts, let A B, fig. 14, Plate XIII. represent the Sun, C D the Earth, and I K or L the Moon in its orbit K M N; let the Moon be at I K, between the Sun and the Earth; its total shadow may then entirely deprive a part of the Earth at O of the Sun's light, and its penumbra will cause a partial eclipse of the Sun to the inhabitants between G and H. Again, suppose the Moon to be at L, and it will itself be eclipsed by the interposition of the Earth between it and the Sun. In lunar eclipses, the Earth's penumbra is not attended to, because its effects in obscuring the Moon cannot be observed with precision by a spectator placed on the Earth.

Eclipses can only happen when the Moon is near one of the nodes of its orbit. Let A B M, fig. 15, represent the Sun, viewed from the earth; C D a portion of the ecliptic, or Sun's apparent path; and E F a part of the orbit of the Moon, which planet is represented at different times by the circles, G, H, I. It is evident, that the eclipse or obscuration of the Sun entirely depends on the position of the node N, and the angle of inclination F N D. If the angle of inclination remain unaltered while the node N is very remote from the centre K of the Sun, the points K and L may be further apart than to permit any occultation or apparent contact; and it is clear, that an enlargement of the angle F N D may produce the same effect: on the contrary, an approach or coincidence of N with K, or a diminution of the angle F N K, may cause an eclipse, the quantity of obscuration in which will be so much greater, as these circcumstances are more prevalent.

The Sun's place K in the ecliptic being known from tables, together with the inclination of the Moon's orbit, the place of the node, and of the Moon itself, and likewise the apparent diameters of the luminaries respectively, it will be easy to find the velocity of the Moon in elongation, and consequently the beginning, middle, end, quantity of obscuration, and other requisites, concerning the eclipse. If the computation be made from the tabular places of the heavenly bodies, the result will give the eclipse as seen from the centre of the Earth; because, in all tables where the earth is spoken of, that centre is meant, except otherwise mentioned. But it is required to determine the particulars of the eclipse for a given place on the Earth's surface, and this includes the consideration of parallax. The Sun's parallax being very minute, may in this, and most other cases, be rejected: but the Moon's parallax is so great, that it is at least of as much consequence as any other element whatever. For, on this account, the Moon's apparent path, as seen from the surface of the Earth, is so different from that which it would have when beheld from the centre, that the same conjunction which gives a total eclipse at one place, shall not occasion the smallest obscuration of the Sun when beheld at the same instant from another part of the Earth.

We are now to consider an eclipse of the Moon. It is evident, that the difference in the phenomena of a solar eclipse would not take place if the parallax of each luminary were the same; because, whatever mutation of place the parallax might occasion in the one, the same would be produced in the other, and they would neither approach nor recede from each other on that account. Now the section of the Earth's shadow passed through by the Moon in a lunar eclipse, being at the same distance from the Earth as the Moon itself, must be subject to the same parallax at equal altitudes; and since the individual points of immersion, emersion, or other periods of the eclipse, must in the shadow have the same altitudes as the parts of the Moon they, as it were, lie on and obscure, the effects of parallax must be the same on both. Rejecting, therefore, the consideration of parallax, the Earth's shadow A B, fig. 16. may be taken to occupy a place in the heavens diametrically opposite to the Sun, and having an equal and similar motion to the apparent motion of that luminary: its apparent diameter, seen from the Earth, will be equal to the difference between the apparent diameters of the Earth and Sun, as seen from the moon; or it will be equal to twice the horizontal parallax of the Moon, diminished by the subtraction of the Sun's apparent diameter. And if the inclination of the orbit of the Moon be found, there will be a certain distance of the node N from the centre of the shadow C, that will require the Moon near the opposition to pass through the Earth's shadow, and be consequently eclipsed. From the greater or less distance of the node N, or M, it will be determined whether the eclipse will be partial or total; and from the respective places, the quantity and direction of the relative velocity, together with the apparent magnitudes of the shadow and the Moon, all the particulars of the eclipse may be known without difficulty.

It may with great reason be demanded, how it happens that the Moon, which is affirmed to emit no light of itself, but only by reflection of the Sun, is nevertheless sufficiently luminous, even in the very middle of a total eclipse, to be distinctly seen of a dusky reddish colour. The Earth's atmosphere, or body of air that surrounds it, is the cause of this phenomenon. In fact, the shadow of the Earth itself never extends so far as the Moon's orbit; though the shadow occasioned by the dispersion or reflection of the light that falls on the atmosphere may, with a very small allowance, be taken for the shadow which the Earth would have had if the light had passed close by it without interruption. We cannot with regularity explain the refraction of light in this place. It will therefore be sufficient to observe, that in the event now under consideration the Sun's light falling obliquely on the atmosphere, is bent or turned out of its course, so as to converge sooner to a point than it would otherwise have done; the spherical atmosphere performing, in some measure, the office of a large convex lens, or burning glass. The more obliquely the rays fall, the greater is their deviation from their original course; and those rays that pass close to the Earth are found, by observations on the setting Sun and other heavenly bodies, to suffer a refraction of about 33 minutes of measure. The laws of optics, hereafter to be explained, require that they should undergo an equal

refraction in passing out through the opposite part of the atmosphere. Each exterior ray of the real shadow, will therefore pass 66 minutes within the rays that would have formed the cone C K D, fig. 13, and consequently, the angle at the vertex of the cone will be 132 minutes, or 2° 12′, greater than it would have been; that is, it will be equal to the diameter of the Sun 32, added to 2° 12′, which gives 2° 44′. Hence the axis of the cone, or length of the shadow, is found to be no more than 42 semidiameters of the Earth; whereas the radius of the Moon's orbit, or mean distance of the moon, is about 60 semidiameters of the Earth. In the space between the penumbra and the Earth's real shadow, it is much darker than the penumbra, though that space is illuminated by the rays of the Sun; which are variously refracted, according to the density of the air they pass through. Many rays are reflected back, and the rays that go forward are such whose nature does not admit of their being easily reflected. Hence it is that the Moon in an eclipse appears red; and a spectator on the Moon would, after losing sight of the Sun, behold the Earth environed with a narrow luminous edge of bright red light, shaded off with yellow on the outside.

Of the Tides.

The first person who clearly pointed out the cause of the tides, and showed its agreement with the effects, was sir Isaac Newton. The Moon he presently saw was the principal agent which produces these motions of the waters; and, by applying his new principles of geometry and attraction, he soon showed the manner in which they are effected. To follow him through all his calculations and inquiries, would carry us beyond our limits.

The ocean, it is well known, covers more than one half the globe; and this large body of water is found to be in continual motion, ebbing and flowing alternately, without the least intermission. For instance, if the tide is now at high water mark, in any port or harbour which lies open to the ocean, it will presently subside, and flow regularly back for about six hours, when it will be found at low water mark. After this, it will again gradually advance for six hours; and then return back, in the same time, to its former situation, rising and falling alternately twice a day, or in the space of about twenty-four hours. The interval between its flux and reflux is, however, not precisely six hours, but there is a little difference in each tide; so that the time of high water does not always happen at the same hour, but is about three quarters of an hour later every day, for about thirty days, when it again recurs as before. For example, if it is high water today at noon, it will be low water at eleven minutes after six in the evening; and consequently, after two changes more, the time of high water the next day will be at about three quarters of an hour after noon; the day following it will be at about half an hour after one, the day after that at a quarter past two, and so on for thirty days; when it will again be found to be high water at noon, as on the day the observation was first made. And this exactly answers to the motion of the moon: she rises every day about three quarters of an hour later than upon the preceding one; and, by moving in this manner round the earth, completes her revolution in about thirty days, and then begins to rise again at the same time as before.

To make the matter still plainer; suppose, at a certain place, it is high water at three o'clock in the afternoon, upon the day of the new moon; the following day it will be high water at three quarters of an hour after three; the day after that at half an hour past four; and so on till the next new moon, when it will again be high water exactly at three o'clock, as before. And by observing the tides continually at the same place, they will always be found to follow the same rule; the time of high water, upon the day of every new moon, being exactly at the same hour; and three quarters of an hour later every succeeding day.

The nature of the tides is in such exact conformity with the motion of the Moon, that, independent of all mathematical considerations, a considerate person would certainly be induced to look to her as their cause.

Neglecting therefore, for the present, all such exceptions as affect not the truth of the theory, we shall now proceed to show, from the Newtonian principles, that these phenomena are occasioned principally by the Moon's attraction.

The waters at Z on the side of the earth, ABCDEFGH, next the Moon M, fig. 17, are more attracted than the central parts of the earth O, by the Moon, and the central parts are more attracted by her than the waters on the opposite side of the earth at *n*; and therefore the distance between the earth's centre and the waters on its surface under and opposite to the Moon will be increased. For, let there be three bodies at H, O, and D; if they are all equally attracted by the body M, they will all move equally fast toward it, their mutual distances from each other continuing the same. If the attraction of M is unequal, then that body which is most strongly attracted will move fastest, and this will increase its distance from the other body. M will attract H more strongly than it does O, by which the distance between H and O will be increased, and a spectator on O will perceive H rising higher toward Z. In like manner O being more strongly attracted than D it will move further toward M than D does; consequently the distance between O and D will be increased; and a spectator on O, not perceiving his own motion, will see D receding further from him toward *n*; all effects and appearances being the same, whether D recedes from O, or O from D.

Suppose now there is a number of bodies, as A, B, C, D, E, F, G, H, placed round O, so as to form a flexible or fluid ring: then, as the whole is attracted toward M, the parts at H and D will have their distance from O increased: whilst the parts at B and F being nearly at the same distance from M as O is, these parts will not recede from one another; but rather by the oblique attraction of M, they will approach near to O. Hence, the fluid ring will form itself into an ellipse Z *n* L N, whose longer axis *n* O Z produced, will pass through M, and its shorter axis B O F will terminate in B and F. Let the ring be filled with fluid particles, so as to form a sphere round O; then, as the whole moves toward M, the fluid sphere being lengthened at Z and *n* will assume an oblong or oval form. If M is the Moon, O the Earth's centre, A B C D E F G H the sea covering the earth's surface, it is evident, by the above reasoning, that whilst the Earth by its gravity falls toward the Moon, the water directly below at H will swell and rise gradually toward her; also the water at D will recede from the centre,

strictly speaking, the centre recedes from D; and rise on the opposite side of the Earth; whilst the water at B and F is depressed, and falls below the former level. Hence as the Earth turns round its axis from the Moon to the Moon again in 24$\frac{3}{4}$ hours, there will be two tides of flood and two of ebb in that time, as we find by experience.

That this doctrine may be still more clearly understood, let it be considered, that although the Earth's diameter bears a considerable proportion to the distance of the Earth from the Moon, yet this diameter is almost nothing when compared to the distance of the Earth from the Sun. The difference of the Sun's attraction, therefore, on the sides of the Earth under and opposite to him, will be much less than the difference of the Moon's attraction on the sides of the Earth under and opposite to her; and, for this reason, the Moon must raise the tides much higher than they can be raised by the Sun. Newton has calculated the effect of the Sun's influence, in this case, and found that it is about three times less than that of the Moon. The action of the Sun alone would, therefore, be sufficient to produce a flux and reflux of the sea; but the elevations and depressions occasioned by this means would be about three times less than those produced by the Moon.

The tides, then, are not the sole production of the Moon, but of the joint forces of the Sun and Moon together. Or, properly speaking, there are two tides, a solar one, and a lunar one, which have a joint or opposite effect, according to the situation of the bodies which produce them. When the actions of the Sun and Moon conspire together, as at the time of new and full Moon, the flux and reflux become more considerable; and these are then called the Spring Tides. But one tends to elevate the waters, whilst the other depresses them, as at the Moon's first and third quarters, and then the effect will be exactly the contrary; the flux and reflux, instead of being augmented, as before, will now be diminished; and these are called the Neap Tides.

To explain this more completely, let S represent the Sun, fig. 18, Z H R the Earth, and F and C the Moon at her full and change. Then, because the Sun S, and the new Moon C, are nearly in the same right line with the centre of the Earth O, their actions will conspire together, and raise the water above the zenith Z, or the point immediately under them, to a greater height than if only one of these forces acted alone. But it has been shown that when the ocean is elevated to the zenith Z, it is also elevated at the opposite point, or nadir, at the same time; and therefore, in this situation of the Sun and Moon, the tides will be augmented. And again, whilst the full Moon F raises the waters at N and Z, directly under and opposite to her, the Sun S, acting in the same right line, will also raise the waters at the same point Z and N, directly under and opposite to him; and therefore, in this situation also, the tides will be augmented; their joint effect being nearly the same at the change as at the full; and in both cases they occasion what are called the Spring Tides.

On this theory, the tides ought to be highest directly under and opposite to the Moon; that is, when the Moon is due north and south. But we find that in open seas, where the waters flow freely, the Moon is generally past the north and south meridian of the place where it is high water. The reason is obvious; for though the Moon's attraction was to cease altogether when she was past the meridian, yet the motion of ascent communicated to the water before that time would make it continue to rise for some time after; much more must it do so when the attraction is only diminished; as a little impulse given to a moving ball will cause it still to move further than otherwise it could have done; and as experience shows that the day is hotter about three in the afternoon, than when the Sun is on the meridian, because of the increase made to the heat already imparted.

Tides answer not always to the same distance of the Moon from the meridian at the same places, but are variously affected by the action of the Sun, which brings them on sooner when the Moon is in her first and third quarters, and keeps them back later when she is in her third and fourth; because, in the former case, the tide raised by the Sun alone would be earlier than the tides raised by the Moon; and in the latter case later.

The Sun, being nearer our hemisphere in winter than in summer, is of course nearer to it in February and October than in March and September, and therefore the greatest tides happen not till some time after the autumnal equinox, and return a little before the vernal.

The sea, being put in motion, would continue to ebb and flow for several times, even though the Sun and Moon were annihilated, and their influence should cease; as if a basin of water was agitated, the water would continue to move for some time after the basin was left to stand still; or like a pendulum, which having been put in motion by the hand, continues to make several vibrations without any new impulse. When the Moon is in the equator, the tides are equally high in both parts of the lunar day, or time of the Moon's revolving from the meridian to the meridian again, which is 24 hours 50 minutes. But as the Moon declines from the equator toward either pole, the tides are alternately higher and lower at places having north or south latitude. For one of the highest elevations, which is that under the Moon, follows her toward the pole to which she is nearest, and the other declines toward the opposite pole; each elevation describing parallels as far distant from the equator, on opposite sides, as the Moon declines from it to either side; and consequently the parallels described by those elevations of the water are twice as many degrees from one another as the Moon is from the equator; increasing their distance as the Moon increases her declination, till it is at the greatest, when these parallels are, at a mean state, 47 degrees from one another; and on that day the tides are most unequal in their heights. As the Moon returns toward the equator, the parallels described by the opposite elevations approach toward each other, until the Moon comes to the equator, and then they coincide. As the Moon declines toward the opposite pole, at equal distances, each elevation describes the same parallel in the other part of the lunar day, which its opposite elevation described before. Whilst the Moon has north declination, the great tides in the northern hemisphere are when she is above the horizon; and the reverse whilst her declination is south.

In open seas the tides rise but to very small heights, in proportion to what they do in wide mouthed rivers, opening in the direction of the stream of tide. For in channels growing narrower gradually, the water is accumulated by the opposition of the contracting bank; like a gentle wind, little felt on an open plain, but strong and brisk in a street;

especially if the wider end of the street is next the plain, and in the way of the wind.

The tides are so retarded in their passage through different shoals and channels, and otherwise so variously affected by striking against capes and headlands, that to different places they happen at all distances of the Moon from the meridian, consequently at all hours of the lunar day. The tide propagated by the Moon in the German Ocean, when she is three hours past the meridian, takes twelve hours to come thence to London bridge, where it arrives by the time that a new tide is raised in the ocean. There are no tides in lakes, because they are generally so small, that when the Moon is vertical she attracts every part of them alike; and therefore, by rendering all the waters equally light, no part of them can be raised higher than another. The Mediterranean and Baltic Seas suffer very small elevations, because the inlets by which they communicate with the ocean are so narrow, that they cannot, in so short a time, receive or discharge enough to raise or sink their surface sensibly.

Air being lighter than water, and the surface of the atmosphere being nearer to the Moon than the surface of the sea, it cannot be doubted that the Moon raises much higher tides in the air than in the sea. And therefore many have wondered why the mercury does not sink in the barometer when the Moon's action on the particles of air makes them lighter as she passes over the meridian. But we must consider, that as these particles are rendered lighter, a greater number of them is accumulated, until the deficiency of gravity is made up by the height of the column; and then there is an equilibrium, and consequently an equal pressure upon the mercury as before; so that it cannot be effected by the aërial tides. It it very probable, however, that the stars which are seen through an aërial tide of this kind will have their light more refracted than those which are seen through the common depth of the atmosphere; and this may account for the supposed refractions by the lunar atmosphere that have been sometimes observed.

Of Comets. Tycho Brahe and Cassini were the first among the modern astronomers who assigned these bodies a place in our system; but they appear to be unacquainted both with their motion round the sun, and the true figure of their orbits. These particulars were left for the determination of Newton, who has discovered the paths they describe, and the laws to which they are subject. Their revolutions are now known to be performed in very long ellipses, whose lower focus is very near the sun; being governed throughout by the same law, of describing equal areas in equal times, which is known to regulate the motions of all the other bodies in the system. By observations of the parallax it is also found, that at their first appearance they are nearer to us than Jupiter; whence it is concluded that they are in general less than that planet; for if they were as large they would be seen at as great a distance. In their motions round the sun they are also subject to the same irregularities as the planets; but as their orbits are extremely eccentric, those variations are much more considerable. When they are near the sun their motion is very rapid, and in the more distant parts of their orbits extremely slow; so that their vicissitudes, in this respect, are as much in the extreme, as what they must undergo from heat and cold.

When a comet arrives within a certain distance of the sun, it emits a fume or vapour called its tail; which shows that they contain a portion of matter considerably more rare and volatile than any on the earth; for the tail begins to appear when they are yet in a higher, and consequently a colder region than Mars. In every situation of the comet, the tail is always directed to that part of the heavens which is nearly opposite to the sun; and it is always greater after the comet has passed its perihelium, than during its approach toward it, being greatest of all when it has just left that point.

The celebrated Dr. Halley, from the theory of Newton, has calculated tables for determining the orbits of the comets, which in several instances have been found agreeable to observation. That remarkable comet which was observed in the year 1680, is shown to be the same with the one that appeared in the year 1106, its period being 575 years. The distance of this comet from the sun when in its perihelium, was to the distance of the earth from the sun, as 6 to 1000; its heat, therefore, at that time, was to the heat of the summer's sun with us, in the ratio of about 28000 to 1; so that, according to Newton, the surface of this comet, supposing it to be composed of a matter like our earth, would have acquired a heat about 2000 times greater than that of red hot iron; which is so intense, that vapours, exhalations, and every volatile matter, must have been immediately consumed and dissipated.

In order to describe the course of a comet, let A B C, fig. 19, be the very long orbit of a comet, in one of whose foci S is placed the Sun; the aphelium in A; the perihelium in P. The comet is not visible to us but when it approaches toward B, and during the time which it passes the arc from B to C of its orbit. But the time is considerably shorter than that which it employs to pass the other portion of its orbit C A B, for these two reasons: first, because the arc B P C is much shorter than the arc C A B; and in the second place, because the comets, like the other planets, are slower in their course while they depart further from the Sun; and on the contrary they are swifter as they approach the Sun. It requires much less time to pass over the portion B P C of their orbit which is visible to us, than the other portion C A B.

As the great eccentricity of the orbits of comets renders them very liable to be disturbed by the attraction of the planets and other comets, it is probably to prevent too great disturbances from these, that while all the planets revolve nearly in the same plane, the comets are disposed in very different cones, and disposed all over the heavens; that when at their greatest distance from the Sun, and moving slowest, they might be removed as far as possible out of the reach of each other's action.

The number of comets belonging to our system is unknown; but from the accounts of the ancients, and the more accurate observations of the moderns, it is ascertained that more than 450 had been seen, previous to the year 1771, and when the attention of astronomers was called to this object, by the expectation of the return of the comet of 1759, no less than seven were observed in the course of as many years. Hence we may reasonably conclude, that their number is considerably beyond any estimate that can be made from the observations of which we are now in possession. For further information on

comets, see vol. 3. of Mott's translation of Newton's Principia.

Of the fixed Stars. The fixed stars are so called, because they are observed not to change their places in the heavens as the planets do. They appear of an infinite variety of sizes, yet for convenience it is usual to class them into six or seven magnitudes: thus they are called stars of the first, second, &c. magnitude. To the naked eye they appear innumerable, but this is only a deception, caused probably by the refraction of our atmosphere. The whole number of stars visible to the naked eye is about 3186; but seldom above one third of that number can be seen by most people.

The ancients, that they might the better distinguish the stars with regard to their situation in the heavens, divided them into several constellations, that is, systems of stars, each system consisting of such as are near each other. And to distinguish these systems from one another, they gave them the names of such men or things as they fancied the space they took up in the heavens represented. To these, several new constellations have been added by modern astronomers.

The following table contains the names of the constellations, and the number of stars observed in each by different astronomers.

The Ancient Constellations.		*Ptolemy.*	*Tycho.*	*Hevelius.*	*Flamsteed.*
Ursa minor	The Little Bear	8	7	12	24
Ursa major	The Great Bear	35	29	73	87
Draco	The Dragon	31	32	40	80
Cepheus	Cepheus	13	4	51	35
Bootes, *Arctophilax*	Bootes	23	18	52	54
Corona Borealis	The Northern Crown	8	8	8	21
Hercules, *Engonasin*	Hercules kneeling	29	28	45	113
Lyra	The Harp	10	11	17	21
Cygnus, *Gallina*	The Swan	19	18	47	81
Cassiopeia	The Lady in her Chair	13	26	37	55
Perseus	Perseus	29	29	46	59
Auriga	The Waggoner	14	9	40	66
Serpentarius, *Ophiuchus*	Serpentarius	29	15	40	74
Serpens	The Serpent	18	13	22	64
Sagitta	The Arrow	5	5	5	18
Aquila, *Vultur* / Antinous	The Eagle / Antinous	15	12 / 3	23 / 19	71
Delphinus	The Dolphin	10	10	14	18
Equulus, *Equi sectio*	The Horse's Head	4	4	6	10
Pegasus, *Equus*	The Flying Horse	20	19	38	89
Andromeda	Andromeda	23	23	47	66
Triangulum	The Triangle	4	4	12	16
Aries	The Ram	18	21	27	66
Taurus	The Bull	44	43	51	141
Gemini	The Twins	25	25	38	85
Cancer	The Crab	23	15	29	83
Leo / Coma Berenices	The Lion / Berenice's Hair	35	30 / 14	49 / 21	95 / 43
Virgo	The Virgin	32	33	50	110
Libra, *Chelæ*	The Scales	17	10	20	51
Scorpio	The Scorpion	24	10	20	44
Sagittarius	The Archer	31	14	22	69
Capricornus	The Goat	28	28	29	51
Aquarius	The Water bearer	45	41	47	108
Pisces	The Fishes	38	36	39	113
Cetus	The Whale	22	21	45	97
Orion	Orion	38	42	62	78
Eridanus, *Fluvius*	Eridanus, *the River*	34	10	27	84
Lepus	The Hare	12	13	16	19
Canis major	The Great Dog	29	13	21	31
Canis minor	The Little Dog	2	2	13	14
Argo Navis	The Ship	45	3	4	64
Hydra	The Hydra	27	19	31	60
Crater	The Cup	7	3	10	31
Corvus	The Crow	7	4	0	9
Centaurus	The Centaur	37	0	0	35
Lupus	The Wolf	19	0	0	24
Ara	The Altar	7	0	0	9
Corona Australis	The Southern Crown	13	0	0	12
Piscis Australis	The Southern Fish	18	0	0	24

The New Southern Constellations.

Columba Noachi	Noah's Dove	10
Robur Carolinum	The Royal Oak	12
Grus	The Crane	13
Phœnix	The Phenix	13
Indus	The Indian	12
Pavo	The Peacock	14
Apus, *Avis Indica*	The Bird of Paradise	11
Apis, *Musca*	The Bee or Fly	4
Chamæleon	The Chameleon	10
Triangulum Australis	The South Triangle	5
Piscis volans, *Passer*	The Flying Fish	8
Dorado, *Xiphias*	The Sword Fish	6
Toucan	The American Goose	9
Hydrus	The Water Snake	10

Hevelius's Constellations made out of the unformed Stars.

		Hevelius.	*Flamsteed.*
Lynx	The Lynx	19	44
Leo minor	The Little Lion		53
Asterion & Ghara	The Greyhound	23	25
Cerberus	Cerberus	4	
Vulpecula & Anser	The Fox and Goose	27	35
Scutum Sobieski.	Sobieski's Shield	7	
Lacerta	The Lizard	10	16
Camelopardalus	The Camelopard	32	58
Monoceros	The Unicorn	19	31
Sextans	The Sextant	11	41

Stars not included in any constellation are called unformed stars. Besides the names of the constellations, the ancient Greeks gave particular names to some single stars, or small collections of stars: thus, the cluster of small stars in the neck of the bull was called Pleiades; five stars in the bull's face the Hyades; a bright star in the breast of Leo, the Lion's Heart; and a large star between the knees of Bootes, Arcturus.

The constellations may be represented on two plane spheres projected on a great circle, or on the convex surface of a solid sphere, as on the celestial globe, or most perfectly on the concave surface of a hollow sphere. If the celestial globe is made use of, after rectifying it to the time of the night, the stars may be found, by conceiving a line drawn from the centre of the globe through any star in the heavens, and its representation upon the globe. Greek letters have been added by Bayer to stars in the several constellations of his catalogue, α being affixed to the largest star, by means of which any star may be easily found.

Twelve of these constellations lie upon the ecliptic, including a space about 15°, broad, called the Zodiac, within which all the planets move. The constellation Aries, about 2000 years ago, lay in the first sign of the ecliptic; but, on account of the precession of the equinoxes, it now lies in the second. In the foregoing table, Antinous was made out of the unformed stars near Aquila: and Coma Berenices, out of the unformed stars near the Lion's Tail. They are both mentioned by Ptolemy, but as unformed stars. The constellations as far as the triangle, with Coma Berenices, are northern; those after Pisces are southern.

The fixed stars are placed at a distance from us so great, that it cannot be ascertained by any means yet known; hence they must shine by their own light, and not by the light which they receive from our sun, as the planets do. Though it has been said that the relative situations of the fixed stars do not vary, yet in the course of several ages, some variations have been observed among them. Some of the larger stars have not the same precise situations that ancient observations attribute to them, and new stars have appeared, while some others which have been described are now no longer to be found. Some stars are likewise found to have a periodical increase and decrease. Many of the fixed stars, upon examination with the telescope, are found to consist of two.

Besides the phenomena already mentioned, there are many nebulæ, or parts of the heavens, which are brighter than the rest. The most remarkable of these is a broad irregular zone or belt, called the milky way. There are others much smaller; and some so small, that they can be seen only by telescopes. If the telescope is directed to these nebulæ, they are resolvable into clusters of stars, which appear as white clouds in instruments of less force.

Dr. Herschel has rendered it highly probable, both from observation and well grounded conjecture, that the starry heaven is replete with these nebulæ or systems of stars, and that the milky way is that particular nebula in which our sun is placed. Reasoning analogically from the circumstances with which we are acquainted, we may deduce, that the universe consists of nebulæ or distinct systems of stars; that each nebula is composed of a prodigious number of suns, or bodies that shine by their own native splendour, and that each individual sun is destined to give light to numbers of worlds that revolve about it. See Vince's Astronomy, Gregory's Astronomy, &c.

ASTROSCOPE, an instrument composed of two cones, having the constellations delineated on their surfaces, whereby the stars may be easily known.

ASTRUM, a constellation or assemblage of stars. This term is often applied to the canis major, or rather to the bright star in his mouth.

ASTYNOMI, in Grecian antiquity, magistrates in Athens, corresponding to the ædiles of the Romans; they were ten in number.

ASYLUM, a sanctuary or place of refuge, where criminals sheltered themselves from the hands of justice. It is pretended that the first asylum was built at Athens by the Heraclidæ, as a refuge for those who fled from the oppression of their fathers. Romulus, when he built Rome, left a certain space as an asylum to all persons, whether freemen or slaves. The Jews had their asyla, the most remarkable of which were the six cities of refuge, the temple, and the altar of burnt offerings. This privilege began likewise to be enjoyed by the Christian churches in the reign of Constantine, at which time the altar only and the inward fabric of the church were a place of refuge; but afterward the whole precincts, nay, even the graves of the dead, crosses, schools, &c. were comprehended in that privilege. As asyla were not intended originally to patronize wickedness, but as a refuge for the innocent, the injured, and the oppressed, several crimes were excepted by law, for which the church could grant no protection; as, 1. Protection was denied to public debtors. 2. To Jews who pretended to turn Christians, in order to avoid suffering legal punishment for their crimes. 3. To heretics and apostates. 4. To slaves who fled from their masters. And, 5. to robbers, murderers, conspirators, ravishers, &c.

ASYMPTOTE, in geometry, a line which continually approaches nearer to another, but though continued infinitely will never meet with it; of these there are many kinds. In strictness, however, the term asymptotes is appropriated to right lines, which approach nearer and nearer to some curve, of which they are said to be the asymptotes; but if they and their curve are indefinitely continued, they will never meet. See Conic Sections.

Concerning asymptotes and asymptotical curves, it may be remarked, 1. that although such curves as have asymptotes are of the number of those which do not include a space; yet it is not true, on the other hand, that wherever we have a curve of that nature, we have an asymptote also. 2. Of these curves that have an asymptote, some have only one, as the conchoid, cissoid, and logarithmic curve; and others too, as the hyperbola. 3. As a right line and a curve may be asymptotical to one another, so also may curves and curves; such are two parabolas, whose axes are in the same right line. 4. No right line can ever be an asymptote to a curve that is every where concave to that right line. 5. But a right line may be an asymptote to a mixed curve, that is partly concave, and partly convex, toward the same line. And, 6. all curves that have one and the same common asymptote are also asymptotical to one another.

ASYNDETON, in grammar, a figure which omits the conjunction in a sentence.

ATCHE, in commerce, a small silver coin used in Turkey, and worth only one third of the English penny.

ATCHIEVEMENT, in heraldry, denotes the arms of a person, or family; together with all the exterior ornaments of the shield, as helmet, mantle, crest, scrolls, and motto, together with such quarterings as may have been acquired by alliances, all marshalled in order. It is vulgarly called hatchment; and such are the arms which are commonly hung up in the fronts of houses, and in churches, on the death of persons.

ATHAMADULET, the prime minister of the Persian empire, as the grand vizier is of the Turkish empire.

ATHAMANTA, in botany, a genus of the pentandria digynia class and order, and in the natural method ranking under the 45th order, umbellatæ. The fruit is oblong and striated, and the petals are inflected and emarginated. Of this genus there are nine species, but none of them merit particular notice, except the athamanta cretensis, or daucus creticus, which grows wild in the Levant and the warmer parts of Europe. The flower stalk rises about two feet high, sending out many branches. These have white flowers. The seeds have a warm biting taste, with an agreeable aromatic smell. They are said to be carminative and diuretic, but are little used in practice.

ATHANASIA, *goldilocks*, a genus of the polygamia æqualis order, and syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ discoides. The receptacle is chaffy; the pappus or down chaffy, and very short; and the calyx is imbricated. There are 20 species, all tender plants except one; and none of them possessed of beauty, or any remarkable property yet discovered.

ATHANATI, in Persian antiquity, a body of cavalry consisting of 10,000 men, always complete. They were called athanati because when one of them happened to die, another was immediately appointed to succeed him.

ATHANOR. See Chymistry.

ATHELING, *adeling*, *edling*, *ethling*, or *etheling*, among our Saxon ancestors, was a title of honour properly belonging to the heir apparent, or presumptive, to the crown.

ATHENÆA, in botany, a genus of the class and order octandria monogynia; the cal. is coloured, five parted; corolla none; bristles eight, feathered between the filaments; stigma five parted; caps. globose, one celled, three valved; seeds three to five.

There is one species, a branching shrub of Guinea; the bark, leaves, and fruit, are sharp and aromatic, called caffé diable by the Creoles.

ATHENÆUM, in antiquity, a public place where the professors of the liberal arts held their assemblies, the rhetoricians declaimed, and the poets rehearsed their performances. The three most celebrated athenæa were those at Athens, at Rome, and at Lyons, the second of which was built by the emperor Adrian.

ATHERINA, in ichthyology, a genus of abdominal fishes, distinguished by having the upper jaw rather flat, six rays in the gill membrane, and a silvery stripe on each side of the body. There are five species of this genus: the most remarkable are;

1. Atherina hepsetus, with about 12 rays in the fin next the anus. It is found in the Mediterranean. It is also very common in the sea near Southampton, where it is called a smelt. The highest season is from March to the latter end of May, or beginning of June; in which month it spawns. It never deserts the place; and is con-

stantly taken, except in hard frost. It is also found on other coasts of our island. The length is above 4¼ inches, and the tail is much forked. The fish is semipellucid, covered with scales; the colour silvery, tinged with yellow; beneath the side line is a row of small black spots.

2. Atherina menidea, has 24 rays in the fin next the anus. This is a very pellucid fish, with many black points interspersed; it has many teeth in the lips, but none in the tongue or jaws. It is found in the fresh waters of Carolina, and spawns in April.

ATHEROMA, in medicine, a tumour without pain or discolouring of the skin; containing, in a membranaceous bag, matter like pap, intermixed with hard and stony corpuscles, &c. It is cured by incision.

ATHEROPOGON, in botany, a genus of the class polygamia, order monoecia; there is but one species, the A. apludoides; its essential character is, calyx one valve, two florets, corolla two valves, persisting; flowers in September. It is a native of Pennsylvania. (*a*)

ATHLETÆ, in antiquity, men of remarkable strength and agility, disciplined to perform in the public games.

ATLANTIDES, in astronomy, the same with Pleiades. They are so called as being supposed by the poets to be the daughters of Atlas, who were translated into heaven.

ATLAS, in anatomy, the name by which some call the first vertebra of the neck; so called in allusion to Atlas.

Atlas denotes a book of universal geography, containing maps of all the known parts of the world.

Atlas, in commerce, a sort of silk or satin manufactured in the East Indies, in which gold and silk are so wrought together, as no workman in Europe can imitate. In China they weave long slips of gilt paper into their silks. The same slips of paper are twisted about silk threads so artificially, as to look finer than gold thread, though of no great value.

ATMOSPHERE, a term used to signify the whole of the fluid mass, consisting of air, aqueous and other vapours, electric fluids, &c. which surrounds the earth to a considerable height; and partaking of all its motions, both annual and diurnal.

The composition of that part of our atmosphere properly called air, was till within a few years but very little known. Formerly it was supposed to be a simple, homogeneous, and elementary fluid; but the experiments of Dr. Priestley and others have discovered, that the atmospheric air is in reality a compound, and may be artificially produced by the union of two other kinds of air, *viz.* oxygen, or pure air, and nitrogen or azotic gas. By accurate experiments, the air that we usually breathe is composed of only one fourth part of oxygen air, or perhaps less; the other three parts, or more, consisting of azotic gas or nitrogen.

Atmosphere, *uses of.* The uses of the atmosphere are so many and great, that it seems indeed absolutely necessary, not only to the comfort and convenience of men, but even to the existence of all animal and vegetable life, and to the very constitution of all kinds of matter whatever, and without which they would not be what they are; for by it we live, breathe, and have our being; and by insinuating itself into all the vacuities of bodies, it becomes the great spring of most of the mutations here below; as generation, corruption, dissolution, &c. and without which none of these operations could be carried on.

By the mechanical force of the atmosphere too, as well as its chymical virtues, many necessary purposes are answered. We employ it as a moving power, in the motion of ships, to turn mills, and for other such uses. And it is one of the great discoveries of the modern philosophers, that the several motions attributed by the ancients to a *fuga vacui*, are really owing to the pressure of the atmosphere. Galileo, having observed that there was a certain standard altitude, beyond which no water could be elevated by pumping, took an occasion then to call in question the doctrine of the schools, which ascribed the ascent of water in pumps, to the abhorrence of a vacuum, and instead of it he happily substituted the hypothesis of the weight and pressure of the air. It was with him indeed little better than an hypothesis; since it had not then those confirmations from experiment, afterward found out by his pupil Torricelli, and other succeeding philosophers, particularly Mr. Boyle.

Atmosphere, *salubrity of.* On the tops of mountains, the air is generally more salubrious than in pits or very deep places. Besides the difference arising from the mere difference of altitude, the salubrity of the atmosphere is greatly affected by many other circumstances. The air, when confined or stagnant, is commonly more impure than when agitated and shifted: thus, all close places are unhealthy; and even the air in a bed chamber is less salubrious in a morning, after it has been slept in, than in the evening. Dr. White, in vol. 68. Philos. Trans. gives an account of experiments on this quality of the air; and remarks one instance when the air was particularly impure, *viz.* Sept. 13, 1777; when the barometer stood at 30° 30′, the thermometer at 69 degrees; the air being then dry and sultry, and no rain having fallen for more than two weeks. A slight shock of an earthquake was perceived that day. In vol. 70 of the same Transactions, Dr. Ingenhousz gives an account of some experiments on this head, made in various places and situations: he finds, "that the air at sea, and close to it, is in general purer, and fitter for animal life, than the air on the land;" but the doctor did not find much difference between the air of the towns and of the country, nor between one town and another. The abbé Fontana made nearly the same conclusions, from accurate experiments, asserting, "that the difference between the air of one country and that of another, at different times, is much less than what is commonly believed; and yet that this difference in the purity of the air at different times, is much greater than the difference between the air of the different places observed by him." Finally, M. Fontana concludes, that "nature is not so partial as we commonly believe. She has not only given us an air almost equally good every where at every time, but has allowed us a certain latitude, or a power of living and being in health, in qualities of air which differ to a certain degree. By this it is not meant to deny the existence of certain kinds of noxious air in some particular places; but to own that in general the air is good every where, and that the small differences are not to be feared so much as some people would make us believe. Nor is it meant to speak here of those vapours and other bodies which are accidentally joined to the common air in particular places, but do not change its nature and intrinsical property. This state of the air cannot be known by the test of nitrous air; and those va-

pours are to be considered in the same manner as we should consider so many particles of arsenic swimming in the atmosphere. In this case it is the arsenic, and not the degenerated air, that would kill the animals who ventured to breathe it." See CHYMISTRY.

ATMOSPHERE, *figure of.* As the atmosphere envelops all parts of the surface of our globe, if they both continued at rest, and were not endowed with a diurnal motion about their common axis, then the atmosphere would be exactly globular, according to the laws of gravity; for all the parts of the surface of a fluid in a state of rest must be equally removed from its centre. But as the earth and the ambient parts of the atmosphere revolve uniformly together about their axis, the different parts of both have a centrifugal force; the tendency of which is more considerable, and that of the centripetal less, as the parts are more remote from the axis; and hence the figure of the atmosphere must become an oblate spheroid, since the parts that correspond to the equator are further removed from the axis than the parts which correspond to the poles. Besides, the figure of the atmosphere must, on another account, represent a flattened spheroid; namely, because the sun strikes more directly the air which encompasses the equator, and is comprehended between the two tropics, than that which pertains to the polar regions; for from this it follows, that the mass of air, or part of the atmosphere, adjoining to the poles, being less heated, cannot expand so much, nor reach so high. And yet, notwithstanding, as the same force which contributes to elevate the air diminishes its gravity and pressure on the surface of the earth, higher columns of it about the equatorial parts, all other circumstances being the same, may not be heavier than those about the poles.

In the transactions of the Royal Irish Academy for 1788, Mr. Kirwin has an ingenious dissertation on the figure, height, weight, &c. of the atmosphere. He observes, that in the natural state of the atmosphere, that is, when the barometer would every where, at the level of the sea, stand at 30 inches, the weight of the atmosphere, at the surface of the sea, must be equal all over the globe; and in order to produce this equality, as the weight proceeds from its density and height, it must be lowest where the density is greatest, and highest where the density is least; that is, highest at the equator and lowest at the poles, with several intermediate gradations.

ATMOSPHERE, *weight or pressure of.* It is evident that the mass of the atmosphere, in common with all other matter, must be endowed with weight and pressure; and this principle was asserted by almost all philosophers, both ancient and modern. But it was only by means of the experiments made with pumps and the barometrical tube, by Galileo and Torricelli, that we came to the proof, not only that the atmosphere is endued with a pressure, but also what the measure and quantity of that pressure is. Thus it is found that the pressure of the atmosphere sustains a column of quicksilver in the tube of the barometer, of about 30 inches in height; it therefore follows, that the whole pressure of the atmosphere is equal to the weight of a column of quicksilver of an equal base, and 30 inches height; and because a cubical inch of quicksilver is found to weigh nearly half a pound avoirdupoise, therefore the whole 30 inches, or the weight of the atmosphere on every square inch of surface, is equal to 15 pounds. Again, it has been found that the pressure of the atmosphere balances, in the case of pumps, &c. a column of water of about $34\frac{1}{2}$ feet high; and the cubical foot of water weighing just 1000 ounces, or $62\frac{1}{2}$ pounds, $34\frac{1}{2}$ times $62\frac{1}{2}$, or $2158lb.$ will be the weight of the column of water, or of the atmosphere, on a base of a square foot; and consequently the 144th part of this, or $15lb.$ is the weight of the atmosphere on a square inch, the same as before. Hence Mr. Cotes computed, that the pressure of this ambient fluid on the whole surface of the earth, is equivalent to that of a globe of lead of 60 miles in diameter. And hence also it appears, that the pressure upon the human body must be very considerable; for as every square inch of surface sustains a pressure of 15 pounds, every square foot will sustain 144 times as much, or 2160 pounds; then if the whole surface of a man's body is supposed to contain 15 square feet, which is pretty near the truth, he must sustain 15 times 2160, or 32400 pounds, that is, nearly $14\frac{1}{2}$ tons weight, for his ordinary load. By this enormous pressure we should undoubtedly be crushed in a moment, if all parts of our bodies were not filled either with air or some other elastic fluid, the spring of which is just sufficient to counterbalance the weight of the atmosphere. But whatever this fluid may be, it is certain that it is just able to counteract the weight of the atmosphere, and no more; for if any considerable pressure is superadded to that of the air, as by going into deep water, it is always severely felt, let it be ever so equable, at least when the change is made suddenly; and if, on the other hand, the pressure of the atmosphere is taken off from any part of the human body, as the hand for instance, when put over an open receiver, whence the air is afterward extracted, the weight of the external atmosphere then prevails, and we imagine the hand strongly sucked down into the glass.

The difference in the weight of the air which our bodies sustain at one time more than another, is also very considerable, from the natural changes in the state of the atmosphere. This change takes place chiefly in countries at some distance from the equator; and as the barometer varies at times from 28 to 31 inches, or about one tenth of the whole quantity, it follows that this difference amounts to about a ton and a half on the whole body of a man, which he therefore sustains at one time more than at another. On the increase of this natural weight, the weather is commonly fine, and we feel ourselves what we call braced and more alert and active; but on the contrary, when the weight of the air diminishes, the weather is bad, and people feel a listlessness and inactivity about them. And hence it is no wonder that persons suffer very much in their health, from such changes in the atmosphere, especially when they take place very suddenly, for it is to this circumstance chiefly that a sensation of uneasiness and indisposition is to be attributed: thus, when the variations of the barometer and atmosphere are sudden and great, we feel the alteration and effect on our bodies and spirits very much; but when the change takes place by very slow degrees, and by a long continuance, we are scarcely sensible of it; owing, undoubtedly, to the power with which the body is naturally endowed, of accommodating itself to this change in the state of the air, as well as to the change of many other circumstances of life; the body requiring a certain interval of time to effect the

alteration in its state, proper to that of the air, &c. Thus, in going up to the tops of mountains, where the pressure of the atmosphere is diminished two or three times more than on the plain below, little or no inconvenience is felt from the rarity of the air, if it is not mixed with other noxious vapours, &c. because in the ascent the body has had sufficient time to accommodate itself gradually to the slow variation in the state of the atmosphere; but when a person ascends with a balloon very rapidly to a great height in the atmosphere, he feels a difficulty in breathing and an uneasiness of body; and the same is soon felt by an animal when enclosed in a receiver, and the air suddenly drawn or pumped out of it. So also, on the condensation of the air, we feel little or no alteration in ourselves, except when the change happens suddenly; as in very rapid changes in the weather, and in descending to great depths in a diving bell.

It is not easy to assign the true reason for the variations that happen in the gravity of the atmosphere in the same place. One cause of it, however, either immediate or otherwise, it seems, is the heat of the sun; for where this is uniform, the changes are small and regular: thus between the tropics it seems the change depends on the heat of the sun, as the barometer constantly sinks about half an inch every day, and rises again to its former station in the night time; but in the temperate zones the barometer ranges from 28 to near 31 inches, showing by its various altitudes the changes that are about to take place in the weather. If we could know, therefore, the causes by which the weather is influenced, we should also know those by which the gravity of the atmosphere is affected. These may perhaps be reduced to immediate ones, *viz.* an emission of latent heat from the vapour contained in the atmosphere, or of electric fluid from the same, or from the earth; as it is observed that both produce the same effect with the solar heat in the tropical climates, *viz.* to rarefy the air, by mixing with it, or setting loose a lighter fluid, which did not before act in such large proportion in any particular place.

Atmosphere, *height and density of.* Various attempts have been made to ascertain the height to which the atmosphere is extended all round the earth. These commenced soon after it was discovered, by means of the Torricellanian tube, that air is endued with weight and pressure. And had not the air an elastic power, but was it every where of the same density, from the surface of the earth to the extreme limit of the atmosphere, like water, which is equally dense at all depths, it would be a very easy matter to determine its height from its density, and the column of mercury which it would counterbalance in the barometer tube; for it having been observed that the weight of the atmosphere is equivalent to a column of 30 inches, or $2\frac{1}{2}$ feet of quicksilver, and the density of the former to that of the latter as 1 to 11040; therefore the height of the uniform atmosphere would be 11040 times $2\frac{1}{2}$ feet; that is, 27600 feet, or little more than five miles and a quarter. But the air, by its elastic quality, expands and contracts, and it being found by repeated experiments in most countries of Europe, that the spaces it occupies, when compressed by different weights, are reciprocally proportional to those weights themselves; or that the more the air is pressed, so much the less space it occupies; it follows that the air in the upper regions of the atmosphere must grow continually more and more rare, as it ascends higher; and indeed that, according to that law, it must necessarily be extended to an indefinite height. Now, if we suppose the height of the whole divided into innumerable equal parts, the quantity of each part will be as its density: and the weight of the whole incumbent atmosphere being also as its density; it follows that the weight of the incumbent air is every where as the quantity contained in the subjacent part; which causes a difference between the weights of each two contiguous parts of air. But by a theorem in arithmetic, when a magnitude is continually diminished by the like part of itself, and the remainders the same, these will be a series of continued quantities decreasing in geometrical progression; therefore if, according to the supposition, the altitude of the air, by the addition of new parts into which it is divided, continually increases in arithmetical progression, its density will be diminished, or, which is the same thing, its gravity decreased, in continued geometrical proportion. And hence, again, it appears that, according to the hypothesis of the density being always proportional to the compressing force, the height of the atmosphere must necessarily be extended indefinitely. And further, as an arithmetical series adapted to a geometrical one, is analogous to the logarithms of the geometrical one; it follows therefore that the altitudes are proportional to the logarithms of the densities, or weights, of air; and that any height taken from the earth's surface, which is the difference of two altitudes to the top of the atmosphere, is proportional to the difference of the logarithms of the two densities there, or to the logarithm of the ratio of those densities, or their corresponding compressing forces, as measured by the two heights of the barometer there. This law was first observed and demonstrated by Dr. Halley, from the nature of the hyperbola; and afterward by Dr. Gregory, by means of the logarithmic curve. See Philos. Trans. No. 181, or Abridg. vol. 2. p. 13, and Greg. Astron. lib. v. prop. 3.

It is now easy, from the foregoing property, and two or three experiments, or barometrical observations, made at known altitudes, to deduce a general rule to determine the absolute height answering to any density, or the density answering to any given altitude above the earth. And accordingly calculations were made upon this plan by many philosophers, particularly by the French; but it having been found that the barometrical observations did not correspond with the altitudes as measured in a geometrical manner, it was suspected that the upper parts of the atmospherical regions were not subject to the same laws with the lower ones, in regard to the density and elasticity. It has, however, been discovered, that the law above given holds very well for all such altitudes as are within our reach, or as far as to the tops of the highest mountains on the earth, when a correction is made for the difference of the heat or temperature of the air only; as was fully evinced by M. De Luc, in a long series of observations, in which he determined the altitudes of hills both by the barometer and by geometrical measurement, from which he deduced a practical rule to allow for the difference of temperature. See his Treatise on the Modifications of the Atmosphere. Similar rules have also been deduced from accurate experiments, by Sir George Shuckburgh and general Roy, both concurring to

show that such a rule for the altitudes and densities, holds true for all heights that are accessible to us, when the elasticity of the air is corrected on account of its density: and the result of their experiments showed, that the difference of the logarithms of the heights of the mercury in the barometer, at two stations, when multiplied by 10000, is equal to the altitude in English fathoms, of the one place above the other; that is, when the temperature of the air is about 31 or 32 degrees of Fahrenheit's thermometer, and a certain quantity, more or less, according as the actual temperature is different from that degree.

But it may here be shown, that the same rule may be deduced independent of such a train of experiments as those above, merely by the density of the air at the surface of the earth alone. Thus, let D denote the density of the air at one place, and d the density at the other; both measured by the column of mercury in the barometrical tube: then the difference of altitude between the two places will be proportional to the log. of D — the log. of d, or to the log. of $\frac{D}{d}$. But as this formula expresses only the relation between different altitudes, and not the absolute quantity of them, assume some indeterminate, but constant quantity h, which multiplying the expression log. $\frac{D}{d}$, may be equal to the real difference of altitude a; that is, $a = h \times \text{log. of } \frac{D}{d}$. Then, to determine the value of the general quantity h, let us take a case in which we know the altitude a, which corresponds to a known density d; as for instance, taking $a = 1$ foot, or 1 inch, or some such small altitude: then, because the density D may be measured by the pressure of the whole atmosphere, or the uniform column of 27600 feet, when the temperature is 55°; therefore 27600 feet will denote the density D at the lower place, and 27599 the less density d at 1 foot above it; consequently $1 = h \times \text{log. of } \frac{27600}{27599}$, which, by the nature of logarithms, is nearly $= h \times \frac{.43429448}{27600}$, or $\frac{1}{63551}$ nearly; and hence we find $h = 63551$ feet; which gives us this formula for any altitude a in general, *viz.* $a = 63551 \times \text{log. of } \frac{D}{d}$, or $a = 63551 \times \text{log. of } \frac{M}{m}$ feet, or $10592 \times \text{log. of } \frac{M}{m}$ fathoms; where M denotes the column of mercury in the tube at the lower place, and m that at the upper. This formula is adapted to the mean temperature of the air 55°: but it has been found, by the experiments of sir George Shuckburgh and general Roy, that for every degree of the thermometer, different from 55°, the altitude a will vary by its 435th part; hence, if we would change the factor h from 10592 to 10000, because the difference 592 is the 18th part of the whole factor 10592, and because 18 is the 24th part of 435; therefore the change of temperature, answering to the change of the factor h, is 24°; which reduces the 55° to 31°. So that, $a = 10000 \times \text{log. of } \frac{M}{m}$ fathoms, is the easiest expression for the altitude, and answers to the temperature of 31°, or very nearly the freezing point: and for every degree above that, the result must be increased by so many times its 435th part, and diminished when below it.

From this theorem it follows, that, at the height of $3\frac{1}{2}$ miles, the density of the atmosphere is nearly twice rarer than it is at the surface of the earth; at the height of 7 miles, 4 times rarer; and so on, according to the following table:

Height in miles.	Number of times rarer.
$3\frac{1}{2}$	2
7	4
14	16
21	64
28	256
35	1024
42	4096
49	16384
56	65536
63	262144
70	1048576

And, by pursuing the calculations in this table, it might be easily shown, that a cubic inch of the air we breathe would be so much rarefied at the height of 500 miles, that it would fill a sphere equal in diameter to the orbit of Saturn.

ATOM, in philosophy, a particle of matter, so minute as to admit of no division.

ATONIA, or ATONY, in medicine, a word that signifies want of firmness, or strength, in the muscular fibre. This condition takes place in most forms of chronic diseases, and in the convalescent period of acute diseases.

ATONICS, in grammar, words not accented.

ATRA BILIS, the black bile, one of the humours of the ancient physicians; which the moderns call melancholy. See MEDICINE.

ATRACTYLIS, in botany, a genus of the syngenesia polygamia class of plants. The corolla is radiated; and each of the little corollæ of the radius has 2 teeth. There are 8 species.

1. Atractylis cancellata, or small cnicus, is an annual plant, rising about eight or nine inches high, with a slender stem; at the top of the branches are sent out two or three slender stalks, each terminated by a head of flowers, like those of the thistle, and of a purplish colour.

2. Atractylis gummifera, or prickly gum bearing cnicus, known among physicians by the name of carline thistle, is a perennial plant. It has many florets enclosed in a prickly empalement. Those on the border are white; but such as compose the disk, are of a yellowish colour. It flowers in July, but never perfects seeds in Britain. Its roots were formerly used as a warm diaphoretic and alexipharmic; but the present practice has entirely rejected them.

3. Atractylis humilis, or purple prickly cnicus, rises about a foot high, with purple flowers. All these plants are natives of the warm parts of Europe; as Spain, Sicily, and the Archipelago islands.

ATRAGENE, in botany: a genus of the polyandria order, and polygamia class of plants. The calyx has four leaves; the petals are twelve; and the seeds are caudated. There are five species, all natives of the East.

ATRAPHAXES, in botany, a genus of the digynia order and hexandria class of plants; and in the natural method ranking under the 12th order, holoracæ. The calyx has two leaves; the petals are two, and sinuated; and there is but one seed. There are two species, both natives of warm countries.

ATRESIA, the state of persons who want some natural aperture.

ATRETI, persons in whom the anus, vagina, urethra, &c. are imperforate, whether naturally or occasioned by disease.

ATRIPLEX, ORACH, or ARRACH: a genus of the monoecia order, and polygamia class; and, in the natural method, ranking under the twelfth order, holoracæ. The calyx of the hermaphrodite flower is five parted; there is no corolla; the stamina are five, and the stylus is bifid; the seed is one, and depressed. There are 14 species, of which the following are the most remarkable.

1. Atriplex halimus, the broad leaved orach, was formerly cultivated in gardens as a shrub, by some formed into hedges, and constantly sheared to keep them thick; but this is a purpose to which it is by no means adapted, as the shoots grow so numerous, that it is impossible to keep the hedge in any tolerable order; and, what is worse, in severe winters, the plants are often destroyed.

2. Atriplex hortensis, the garden orach, was formerly cultivated in gardens, and used as a substitute for spinach; to which it is still preferred by some, though in general it is disliked by the English. There are three or four varieties of this plant, whose only difference is their colour; one is a deep green, another a dark purple, and a third has green leaves and purple borders. They are all annual, and must be propagated by seeds.

3. Atriplex petulacoides, the shrubby sea orach, grows wild by the sea side, in many places of Britain. It may have a place in gardens among other low shrubs, where it will make a pretty diversity. This species requires little culture. It thrives in a poor gravelly soil, and may be propagated from cuttings.

ATROPA, DEADLY NIGHT SHADE: a genus of the monogynia order, and pentandria class of plants; and in the natural method, ranking under the 25th order, luridæ. The corolla is campanulated; the stamina are distant; the berry is globular, and consists of two cells. There are eight species; of which the following are the most remarkable.

1. Atropa belladonna, grows wild in many parts of Britain. It has a perennial root, which sends out strong herbaceous stalks of a purplish colour. These rise to the height of four or five feet, garnished with entire oblong leaves, which toward autumn change to a purple. The flowers are large, and come out singly between the leaves, upon long foot stalks; bell shaped, and of a dusky colour on the outside, but purplish within. After the flower is past, the germen turns to a round berry, a little flatted at the top, about the size of a cherry. It is first green; but when ripe, turns to a shining black, sits close upon the empalement, and contains a purple juice of a nauseous sweet taste, and full of small kidney shaped seeds. This species, being remarkable for its poisonous qualities, is very seldom admitted into gardens. Mr. Ray gives an account of the symptoms that follow the taking of it inwardly, by what happened to a mendicant friar, upon his drinking a glass of mallow wine, in which the herb was infused. In a short time, he became delirious, and soon after was seized with a grinning laughter; then with several irregular motions, and at last, with a real madness, and such a stupidity as those have who are sottishly drunk; but after all, he was cured by a draught of vinegar. Buchanan also gives an account of the destruction of the Danes under Sueno, when they invaded Scotland, by mixing a quantity of the belladonna berries with the drink which the Scots were, according to a treaty of truce, to supply them with. This so intoxicated the Danes, that the Scots fell upon them in their sleep, and killed the greatest part of them, so that there were scarcely men enough left to carry off their king. There have also been many instances in Britain, of children being killed by eating the berries of the belladonna. When an accident of this kind is discovered in time, a glass of warm vinegar will prevent the bad effects.

2. Atropa frutescens, is a native of Spain, and rises with a shrubby stem to the height of six or eight feet. The flowers come out between the leaves, on short foot stalks, shaped like those of the former, but much less; of a dirty yellowish colour, with a few brown stripes; but these are never succeeded by berries in Britain.

3. Atropa herbacea, is a native of Campeachy, and has an herbaceous stalk, rising about two feet. The flowers come out from between the leaves, on short foot stalks; they are white, and shaped like those of the common sort, but smaller. It flowers in July and August, but seldom ripens its fruit in Britain.

4. Atropa mandragora, the mandrake, has been distinguished into the male and female. The male mandrake has a very large, long, and thick root: it is largest at the top or head, and thence gradually grows smaller. Sometimes it is single and undivided to the bottom; but more frequently, it is divided into two or more parts. When only parted into two, it is pretended that it resembles the body and thighs of a man. From this root arise a number of very long leaves, broadest in the middle, and obtusely pointed at the end; they are a foot or more in length, and about five inches in breadth; of a dusky and disagreeable green colour, and of a very fetid smell. The female mandrake perfectly resembles the other in its growth; but the leaves are longer and narrower, and of a darker colour, as are also the seeds and roots. It grows naturally in Spain, Portugal, Italy, and the Levant. These three last species are propagated by seeds, and placed in stoves. This plant has been absurdly recommended as a cure for barrenness. Its fresh root is a violent purge, the dose being from ten to twenty grains in substance, and from half a dram to a dram in infusion. It is also narcotic. It has been found of service in hysteric complaints, but must be used with great caution.

ATROPHY, in medicine, a disease, wherein the body or some of its parts do not receive the necessary nutriment, but waste and decay incessantly. This is a disorder proceeding from the whole habit of the body, and not

from any distemper of the intestines: it is attended with no remarkable fever, and is natural in old age, which is called atrophia senilis. See MEDICINE.

ATTACHMENT, in law, the taking or apprehending of a person, by virtue of a writ, or precept.

It is distinguished from an arrest in this respect; that whereas an arrest lies only on the body of a man, an attachment is often on the goods only, and sometimes on the body and goods; there is this further difference, that an arrest proceeds out of an inferior court by precept only, and an attachment out of a higher court, either by precept or writ.

An attachment by writ differs from distress, insomuch that attachment does not extend to lands, as a distress does; and a distress does not touch the body, as an attachment does.

In the common acceptation, an attachment is the apprehension of a man's body, to bring him to answer the action of the plaintiff.

ATTACHMENT *out of the chancery*, is obtained upon an affidavit made, that the defendant was served with a subpœna, and made no appearance; or it issues upon not performing some order or decree. Upon the return of this attachment by the sheriff, quod non est inventus in balliva sua, another attachment, with a proclamation, issues; and if he appears not thereupon, a commission of rebellion.

ATTACHMENT *of the forest*, is one of the three courts held in the forest. The lowest court is called the court of attachment, or wood mote court; the mean, swan mote; and the highest, the justice in eyre's seat.

This attachment is by three means; by goods and chattels, by body, pledges, and mainprize, or the body only. This court is held every forty days throughout the year, whence it is called forty days court.

ATTACHMENT *of privilege*, is by virtue of a man's privilege to call another to that court whereto he himself belongs, and in respect whereof he is privileged to answer some action.

Foreign ATTACHMENT, is an attachment of money or goods, found within a liberty or city, to satisfy some creditor within such liberty or city.

By the custom of London, and several other places, a man can attach money or goods in the hands of a stranger, to satisfy himself.

ATTACK, in the military art, is an effort made to force a post, break a body of troops, &c.

ATTACK *of a siege*, is a furious assault made by the besiegers with trenches, covers, mines, &c. in order to make themselves masters of a fortress, by storming one of its sides. If there are two or three attacks made at the same time, there should be a communication betwixt them.

ATTACKS, *false*, are never carried on with that vigour and briskness that the other is; the design of them being to favour the true attack, by amusing the enemy, obliging the garrison to a greater duty in dividing their forces, that the true attack may be more successful.

ATTACK *in flank*, is to attack both sides of the bastion.

ATTAINDER, in law, is when a man has committed felony or treason, and sentence is passed upon him for the same. The children of a person attainted of treason, are, thereby, rendered incapable of being heirs to him, or to any other ancestor; and if he was noble before, his posterity are degraded, and made base: nor can this corruption of blood be salved, but by an act of parliament, unless the sentence is reversed by a writ of error.

ATTAINDER, *bill of*, a bill brought into parliament for attainting, condemning, and executing, a person for high treason. A most unconstitutional proceeding.

ATTAINT, in law, attincta, a writ which lies against a jury that have given a false verdict in any court of record, in a real or personal action, where the debt or damages amount to above 40 shillings.

If the verdict is found false, the judgment by common law was, that the jurors' meadows should be ploughed up, their houses broken down, their woods grubbed up, all their lands and tenements forfeited, &c. but by statute the severity of the common law is mitigated, where a petty jury is attainted, and there is a pecuniary penalty appointed.

But if the verdict be affirmed, such plaintiff shall be imprisoned and fined.

ATTELABUS, a genus of coleopterous insects, or beetle kind, distinguished by having the head inclined, and pointed behind; antennæ moniliform, and thickest near the end. The larva of the attalabi attack the leaves, flowers, the fruits, and even the stalks and roots of different plants: but most of the species, of which there are 34, penetrate into the plant, and subsist entirely on the spongy parts within. Preparatory to the pupa state, some species spin a silky web, and others form a little ball of a very solid kind, in which they remain during a second state. The perfect insects inhabit the same plants as the larva, but are deemed less injurious to them. For the character, see Plate. The most remarkable species are:

1. Attelabus apiarius, is bluish, with red elytra, and three black belts. It is a native of Germany.

2. Attelabus avellana, is black; with the breast, feet, and elytra, red.

3. Attelabus betula has springy legs, and the whole body is of a dark red. It frequents the leaves of the birch.

4. Attelabus buprestoides, is of a dark colour, with a globular breast, and nervous elytra. It is a native of Europe.

5. Attelabus ceramboides, is of a blackish red colour, and the elytra is furrowed. It frequents the spongy boletus, a species of mushroom.

6. Attelabus coryli, is black, with red elytra, or crustaceous wings.

7. Attelabus curculionoides, is black, with red elytra and breast. These two last species and the Avellana frequent the leaves of the hazel and filbert nut trees.

8. Attelabus formicarius, is black, with a red elytra, and a double white belt toward the base. It is a native of Europe.

9. Attelabus melanurus, is black, with testaceous elytra, black at the apex. It is a native of Sweden.

10. Attelabus mollis, is hairy and yellowish, with pale elytra, and three belts. It is a native of Europe.

11. Attelabus Pennsylvanicus, is black, with red elytra, a black belt round the middle, and another toward the apex of the elytra. It is a native of Philadelphia.

12. Attelabus sipylus, is green, with a hairy breast, and a double yellow belt upon the elytra.

13. Attelabus Surinamensis, has a double indentation, or two teeth, in the top of the elytra. It is a native of Surinam.

ATTENTION, in regard of hearing, is the stretching the *membrana tympani*, to make it more susceptible of sounds, or adjusting the tension of that membrane to the proper key or tone of the sound.

According to lord Bacon, "sounds are meliorated by the intension of the sense, where the common sense is collected most to the particular sense of hearing, and the sight suspended. Therefore sounds are sweeter and more powerful in the night than in the day, and I suppose they are sweeter to blind men than to others; and it is manifest, that between sleeping and waking, when all the senses are blind and suspended, music is far sweeter than when one is fully waken."

ATTENUANTS, in pharmacy, medicines which resolve the viscosity of the humours in the human body; promoting their circulation, as well as the discharge of all noxious and excrementitious matter.

When these medicines act upon fluids lodged in the capillary vessels, they get the appellation of aperitives, or aperients; as they do that of expectorants, when they promote a discharge of the viscid humours in the lungs.

ATTIC, in architecture, a sort of building wherein the roof or covering is not to be seen; thus named, because the buildings at Athens were generally of this form.

Attic order, a small order raised upon a large one, by way of crowning, or to finish the building: or it is, according to some, a kind of rich pedestal, sometimes used for the conveniency of having a wardrobe, or the like; and instead of columns, has only pilasters of a particular form, and sometimes no pilasters at all.

The name attic is also given to a whole story into which this order enters; this little order being always found over another greater one.

Attic *base*, a peculiar kind of base used by the ancient architects in the Ionic order; and by Palladio, and some others, in the Doric. This is the most beautiful of all bases. See Architecture.

ATTIRE, in hunting, signifies the head and horns of a deer.

ATTITUDE, in painting, &c. the posture or disposition of a figure, expressive of a designed action or end.

ATTOLENS, in anatomy, an appellation given to several muscles, otherwise called levators and elevators. See Anatomy.

ATTORNATO faciendo, &c. a writ commanding a sheriff or steward to admit an attorney to appear for a person who owes suit to the county court, court baron, &c.

ATTORNEY, at law, one who is retained to prosecute, or defend, a law suit.

Attornies, being properly those who sue out writs or process, or commence, carry on, and defend actions, in any of the courts of common law, are distinguished from solicitors, as the latter do the same business in the courts of equity; and none are admitted, either as an attorney or solicitor, unless they have served a clerkship of five years, been enrolled, and taken the oath in that case provided; and the judges of their respective courts are required to examine their several capacities.

By 34 Geo. III. c. 14. a stamp duty of 100*l.* is charged upon all articles of clerkship to an attorney or solicitor. Also, every attorney, solicitor, notary, proctor, or agent, within the bills of mortality, shall annually take out a certificate, charged with a stamp duty of 5*l.* and of 3*l.* in any part of the kingdom.

Attornies may be punished for ill practices; and if an attorney, or his clerks, of which he must have but two at one time articled, do any thing against the express rules of the court, he or they may be committed.

Neither a plaintiff nor defendant may change his attorney without rule of court, whilst the suit is depending: and attornies are not generally obliged to deliver up the writings in their hands, till their fees are satisfied: likewise, an action does not lie against an attorney, for what he advises in the way of his profession: yet if an attorney plead any plea, or appear, without warrant from his client, action of the case lies against him.

Attornies have the privilege to sue and be sued in the courts of Westminster, where they practise; and they shall not be chosen into offices against their will, except the militia.

Attorney, of the duchy of Lancaster, is the second officer in that court.

Attorney general, is a great officer under the king, created by letters patent, whose office it is to exhibit informations, and prosecute for the crown in criminal causes; and to file bills in the exchequer, for any thing concerning the king in inheritance or profits. To him come warrants for making of grants, pardons, &c. his salary from the crown is 1000*l.* per annum.

ATTOURNMENT, or Attornment, in law, a transfer from one lord to another, of the homage and service a tenant makes; or that acknowledgment of duty to a new lord.

ATTRACTION, a general term to denote the principle by which all bodies mutually tend toward each other, without regarding the cause that produces the effect.

It has been found by experience, that all matter, of whatever kind, is subject to certain general laws, and the principal of these are attraction and repulsion. Five different kinds of attraction have been enumerated by modern philosophers. 1. The attraction of cohesion; 2. Of combination, or, as it is called by chymists, elective attraction; 3. Gravity; 4. The magnetic attraction; and, 5. The attraction of electricity. Whether the same principle acts in all these cases, or whether each of these effects depends upon a distinct cause, human sagacity has not been able to discover.

1. The attraction of cohesion may be observed in almost all the common operations of nature, and is exemplified by a variety of easy experiments. Two leaden balls, having each a smooth surface, if strongly compressed together, will cohere almost as strongly as if united by fusion; and even two plates of glass, if the surfaces are even and dry, will require some force to separate them. By the same law of nature the particles of even fluid bodies, in which the attraction is necessarily weaker than in solid substances, indicate a disposition to unite.

The drops of dew that appear in the morning on the leaves of plants assume a globular form, from the mutual attraction between the particles of water. Small portions of quicksilver, when brought near to each other, will run together, and assume the same globular appearance. Also, by the same law, a vessel may be filled with

water, mercury, or any other fluid, above the brim, and the fluid will be observed to rise in a convex form.

To this principle we may very properly refer what is termed capillary attraction. Thus, if a fluid is contained in a vessel not full to the brim, it will always be attracted to the edges of the vessel, and will assume a concave form. Thus, also, if two plates of glass, at a small distance from each other, are immersed perpendicularly in water, the fluid will rise above its level between the two plates, and the height to which it rises will bear a certain proportion to the distance of the plates. A capillary tube is a tube with an exceeding small bore, and by the same law which raises the water between the plates of glass, a fluid will rise to a considerable height in one of these tubes. Both these experiments will answer equally well in the vacuum of an air pump, which proves that the effect is not owing to the pressure of the air. In the same manner also, and by the same law, fluids will ascend in the cavity of a sponge, in the interstices of linen cloth, or any porous body.

2. The attraction of combination, or chymical or elective attraction, is in many respects analogous to the attraction of cohesion. Like the latter, it seems to depend on the minute particles of bodies being brought nearly into contact with each other; and indeed so nearly alike are the effects of these two species of attraction, that if they are different in principle it is difficult to say which is the most essential to the cohesion and solidity of bodies: Chymical attraction may probably be no other than the attraction of cohesion acting in a free and unresisting medium, since its only distinguishing characteristic is the disposition which bodies in solution indicate to unite with certain substances in preference to others. To make this clear by an experiment: If silver is added to a quantity of aquafortis, the cohesion of the particles of silver will be destroyed, and they will unite forcibly with those of the aquafortis. The fluid will however remain perfectly clear; the particles being so extremely minute, that the rays of light will suffer no interruption in passing through them. If however to this solution of silver a quantity of mercury or quicksilver is added, the aquafortis will be attracted by the mercury, and the silver will be precipitated, or thrown to the bottom of the vessel in which the fluid is contained; if again copper is added, it will assume the place of the quicksilver; and if to this solution of copper a bright piece of iron is introduced, the acid will immediately quit the copper, and seize upon the iron, a quantity of which being dissolved in the fluid, and the copper will be deposited in its place on the surface of the bar of iron. The iron may afterward be displaced by the addition of an alkali. This species of attraction is called combination; because the particles of two bodies by those means become so intimately united or combined, that they cannot be separated but by the addition of a third body, which has a greater attraction for one of the component bodies than they have for one another, and it is called elective attraction and affinity, from the superior tendency in substances to unite with certain bodies in preference to others. In all cases of elective attraction it is necessary, that at least one of the bodies should be in a fluid state.

3. The attraction of gravitation materially differs from the two preceding species of attraction, since it requires neither the particles of the bodies, nor the bodies themselves, to be brought into immediate contact, but acts at considerable distances, and in this respect it is analogous to the attraction of magnetism and electricity.

The most obvious effect of gravitation is the general tendency of bodies to the surface, or perhaps to the centre, of the earth. It appears to be one of the great laws of gravitation, that the attraction of bodies is in proportion to the quantity of matter they contain. The earth, therefore, being such an immense aggregate of matter, is supposed to destroy the effect of this attraction between smaller bodies, by forcibly compelling them to itself. The attraction of mountains, however, upon the balls of pendulums, has been found, by repeated observations, to be very considerable.

The efficient cause of this species of attraction is as much a secret as all the other great principles of nature. But first, it appears, that the gravitating force being proportioned always to the quantity of matter, all bodies gravitate from equal distances with equal velocity, except prevented or impeded by some resisting medium. Thus, though a guinea and a feather will not fall to the ground with equal velocity in the open air, because of the resistance of that fluid, yet if the air by any means is removed, as in the vacuum of an air pump, they appear to fall at the very same instant of time: for though the guinea contains considerably more of solid matter than the feather, and consequently requires a more considerable force to put it in motion, yet it appears that the attractive power being proportioned to the quantity of matter, its velocity is equal to that of a body which requires less force to put it in motion.

Secondly, The attractive force of bodies is reciprocally as the square of the distances. Thus, if a body is of the weight of one hundred pounds at the distance of ten diameters of the earth, at half that distance it would have four times that weight, or the force of gravity would be exerted upon it in a quadruple ratio, and so in proportion as it approaches the body of the earth.

4. The attraction of magnetism only differs from that of gravity in its operations being limited to particular substances. The magnet is an ore of iron, and its property of attracting certain portions of that metal at moderate distances is well known. Like the attraction of gravitation, that of magnetism bears a proportion to the distance, and probably to the quantity of magnetic matter in the attracting bodies. But the properties of the magnet are so curious and important in nature, that they well deserve a distinct consideration.

5. The attraction of electricity is also analogous to that of gravity in the property of acting upon bodies at a certain distance; but it differs from it in its operation being confined to a particular state of those bodies, that is, when excited by friction.

Attraction of mountains. See Mountains.

AVADOUTAS, a sect of Indian bramins, distinguished for their austerity and abstinence.

AVAIL of marriage, in Scotch law, denotes a custom, by which the superior was entitled to a certain sum from his vassal, upon his attaining the age of puberty.

AVALANCHES, a name given in Switzerland and Savoy, to those prodigious masses of snow, which are precipitated with a noise like thunder from the mountains,

destroying every thing in their course. They have sometimes overwhelmed whole villages. The best preservative against their effects being the forests with which the Alps abound, there is scarcely a village situated at the foot of a mountain, that is not sheltered by trees, which the people preserve with uncommon reverence. Thus what constitutes one of the principal beauties of the country, affords security also to the inhabitants.

AVANIA, in Turkish customs, a fine for crimes and on deaths, paid to the governor of the place. In cities and towns where several nations live together under a Turkish governor, he takes this profitable method of punishing all crimes among the Christians or Jews, unless it be the murder of a Turk.

AVAST, in the sea language, a term requiring to stop, to hold, or to stay.

AVANTURINE, in natural history, a yellowish stone full of sparkles, resembling gold, very common in France. An artificial imitation of it is made by mixing sparkles of copper with glass whilst it is in fusion, which is used by enamellers, and to sprinkle, as sand, upon writing.

AUBANE, in the old customs of France, a right vested in the sovereign of being heir to a foreigner that died within his dominions. By this right the French sovereign claimed the inheritance of all foreigners that died within his dominions, notwithstanding any testament the deceased could make.

AUBIN, in horsemanship, a broken kind of gait between an amble and a gallop, accounted a defect.

AUBLETIA, in botany, a genus of the class and order polyandria monogynia. The essential character is, cal. five leaved; cor. five petalled; caps. many celled, echinate, with many seeds in each cell. There are three species, all trees, and natives of South America.

AUCTION; sales by auction are subject to many legal regulations: the auctioneer is obliged to take out a license; and is subject to various penalties if he is negligent of certain acts of parliament, made principally since the 19th of the present reign.

AUCUBA, in botany, a genus of the monoecia tetandria class and order. The essential character is: male cal. 4 toothed; cor. 4 petalled; berry 1 seeded; fem. nect. none; nut one celled.

There is but one species of this beautiful tree, the specific name of which is Japonica, to note its native place. Notwithstanding this, it is found to be very hardy; and being easily propagated by cuttings, it is now become very common in our gardens, though it does not seem with us as yet to attain a growth beyond that of a shrub. The leaves are beautifully spotted with white or yellow, and among other shrubs it makes a fine appearance.

AUDIENDO ET TERMINANDO, a commission directed to certain persons when any riotous assembly, insurrection, &c. is committed in any place, for appeasing it, and punishing the offenders.

AUDIENTES, an order of catechumens in the primitive Christian church, consisting of such as were but newly instructed in the mysteries of the Christian religion, and not yet admitted to baptism.

AUDITA QUERELA, a writ that lies where any person has any thing to plead, but has not a day in court for pleading it; or where judgment is given for debt, and the defendant's body in execution; then if he has a release, or other sufficient cause to be discharged therefrom, but wants a day in court to plead the same, this writ may be granted by the lord chancellor, upon view of the exception suggested to the judges of either bench.

AUDITOR *of the receipts*, is an officer of the exchequer who files the tellers' bills, makes an entry of them, and gives the lord treasurer a certificate of the money received the week before. He also makes debentures to every teller, before they receive any money, and takes their accounts. He keeps the black book of receipts, and the treasurer's key of the treasury, and sees every teller's money locked up in the new treasury.

AUDITORY *nerves*, in anatomy, a pair of nerves arising from the medulla oblongata, with two trunks, the one of which is called the portio dura, hard portion, the other portio mollis, or soft portion. See ANATOMY.

AVELLANE, in heraldry, a cross, the quarters of which somewhat resemble a filbert nut.

AVENA, OATS, a genus of the digynia order, belonging to the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The calyx has a double valve, and the awn on the back is contorted. There are 25 species, of which the first six following are natives of England.

1. Avena flatior, tall oat grass.
2. Avena fatua, the bearded oat grass.
3. Avena flavescens, the yellow oat grass.
4. Avena nuda, the naked oat.
5. Avena pratensis, the meadow oat grass.
6. Avena pubescens, the rough oat grass.
7. Avena sativa, the common oats cultivated in our fields. It is remarkable that the original native place of this plant is almost totally unknown. Anson says that he observed it growing wild or spontaneously in the island of Juan Fernandez; but a vague observation from a single author is not to be depended on. Oats are an article of the materia medica. Gruels made from them have a kind of soft mucilaginous quality, by which they obtund acrimonious humours, and prove useful in inflammatory diseases, coughs, hoarseness, and exulcerations of the fauces.

AVENAGE, in law, a certain quantity of oats paid by a tenant to a landlord instead of rent, or some other duties.

AVERAGE, in commerce, is divided into three kinds. 1. The simple or particular average, which consists in the extraordinary expenses incurred for the ship alone, or for the merchandises alone. Such is the loss of anchors, masts, and rigging, occasioned by the common accidents at sea, the damages which happen to merchandise by storm, prize, shipwreck, wet, or rotting; all which must be borne and paid by the thing which suffered the damage. 2. The large and common average, being those expenses incurred, and damages sustained, for the common good and security both of the merchandises and vessels, consequently to be borne by the ship and cargo, and to be regulated upon the whole. Of this number are the goods or money given for the ransom of the ship and cargo, things thrown overboard for the safety of the ship, the expenses of unlading for entering into a river or harbour, and the provisions and hire of the sailors when the ship is put under an embargo. 3. The small averages, which are the expenses for towing and piloting the ship out of or into harbours, creeks, or rivers, one third of which must be charged to the ship, and two thirds to the cargo.

AVERAGE, in agriculture, a term used by farmers, in many parts of England, for the stubble, or remainder of straw and grass left in corn fields after the harvest is carried in. In some counties it is called gratten.

AVERIA, in a general sense, signifies any cattle, but it is used in law for oxen or horses of the plough.

Averia, in commerce, a branch of Spanish revenue that denotes a tax paid on account of convoys to guard the ships sailing to and from America, which was first imposed when sir Francis Drake made his expedition to the South Sea.

AVERMENT, an offer of the defendant to make good an exemption pleaded in abatement, or bar of the plaintiff's action.

Averment, *general*, is the conclusion of every plea to the writ, or in bar of replications, or other pleadings, containing matter affirmative.

Averment, *particular*, is when the life of a tenant for life, or tenant in tail, is averred.

AVERRHOA, in botany, a genus of the decandria order, belonging to the pentagynia class of plants, and in the natural method ranking under the 14th order, gruinales. The calyx has five leaves; the petals are five, opening at top; and the apple or fruit is pentagonous, and divided into five cells. There are two species:

The averrhoa carambola, called in Bengal the camrue or camrunga, is a tree which grows to the height of 14 feet, and is remarkable for possessing a power somewhat similar to those species of mimosa which are termed sensitive plants; its leaves, on being touched, moving very perceptibly. In the mimosa the moving faculty extends to the branches; but from the hardness of the wood this cannot be expected in the carambola. The leaves are alternately pinnated with an odd one; and their most common position in the day time is horizontal. On being touched, they move themselves downward, frequently in so great a degree that the two opposite almost touch one another by their under sides, and the young ones sometimes either come into contact, or even pass each other. The whole of the leaves of one pinna move by striking the branch with the nail of the finger or other hard substance, or each leaf can be moved singly by making an impression that shall not extend beyond that leaf. Notwithstanding this apparent sensibility of the leaf, however, large incisions may be made in it with a pair of sharp scissars, without occasioning the smallest motion; nay, it may even be cut almost entirely off, and the remaining part still continue unmoved, when by touching the wounded leaf with the finger or point of the scissars, motion will take place as if no injury had been offered. The reason is, that although the leaf is the ostensible part which moves, the petiolus is the seat both of sense and action. After sunset the leaves go to sleep, first moving down so as to touch one another by their under sides: they therefore perform more extensive motion at night of themselves than they can be made to do in the day time by external impressions. With a convex lens the rays of the sun may be collected on a leaf, so as to burn a hole in it, without occasioning any motion; but upon trying the experiment on the petiolus, the motion is as quick as if from strong percussion, although the rays be not so much concentrated as to cause pain when applied in the same degree on the back of the hand. The leaves move very fast from the electrical shock, even although very gentle. The fruit of this tree is said to be delicious.

AVERRUNCI, in the ancient heathen theology, an order of deities among the Romans, whose peculiar office it was to avert danger and exile.

AVERSIONE *venire*, in civil law, seems to denote the selling or letting things in the lump, without fixing any particular prices for each piece.

AUGIT, *silex augites*, in mineralogy. The colour of this mineral is a deep olive or pear green: it sometimes occurs in rounded fragments, but more usually crystalized. See Mineralogy.

AUGMENTATION was the name of a court erected 27 Hen. VIII. so called from the augmentation of the revenues of the crown, by the suppression of religious houses; and the office still remains, wherein there are many curious records, though the court has been dissolved long since.

Augmentation, in heraldry, are additional charges to a court armour, frequently given as particular marks of honour.

AUGUR, an officer among the Romans appointed to foretell future events. There was a college or community of them consisting originally of three members, with respect to the three tribes, Luceres, Rhamnenses, and Tatienses: afterward the number was increased to nine, four of whom were patricians, and five plebeians. They bore an augural staff or wand, as the ensign of their authority, and their dignity was so much respected that they were never deposed, nor any substituted in their place, though they should be convicted of the most enormous crimes.

AUGURY, in antiquity, the art of foretelling future events, is distinguished into five sorts. 1. Augury from the heavens. 2. From birds. 3. From chickens. 4. From quadrupeds. 5. From portentous events. When an augury was taken, the augur divided the heavens into four parts, and having sacrificed to the gods, he observed with great attention from what part the sign from heaven appeared. If, for instance, there happened a clap of thunder from the left, it was taken as a good omen. If a flock of birds came about a man, it was a favourable presage, but the flight of vultures was unlucky. If when corn was flung before the sacred chickens, they crowded about it, and ate it greedily, it was looked upon as a favourable omen; but if they refused to eat and drink, it was an unlucky sign.

Augury, in its more general signification, comprises all the different kinds of divination, which Varro distinguishes into four species, according to the four elements, *viz.* pyromancy, or augury by fire; aeromancy, or augury by air; hydromancy, or augury by water; and geomancy, or augury by the earth.

AUGUSTALES, in Roman antiquity, an epithet given to the flamens or priests appointed to sacrifice to Augustus, after his deification, and also to the ludi or games celebrated in honour of the same prince on the fourth of the ides of October.

AUGUSTALIA, a festival instituted by the Romans in honour of Augustus Cæsar, on his return to Rome after having settled peace in Sicily, Greece, Syria, Asia, and Parthia; on which occasion they likewise built an altar to him, inscribed *Fortunæ reduci.*

AUGUSTALIS præfectus, a title peculiar to a Roman magistrate who governed Egypt, with a power much like that of a proconsul in other provinces.

AUGUSTINS, a religious order in the church of Rome, who follow the rule of St. Augustin, prescribed them by pope Alexander IV. Among other things, this rule enjoins to have all things in common; to receive nothing without the leave of the superior; and several other pre-

cepts relating to charity, modesty, and chastity. There are likewise nuns of this order.

The Augustins are clothed in black, and at Paris were known under the name of the religious of St. Genevieve, that abbey being the chief of the order.

AVICIENNA, in botany, a genus of plants of the tetandria monogynia class of Linnæus; the flower of which consists of a single petal, divided into four ovato acuminated segments; the fruit is a coriaceous capsule of one cell, containing a single seed of an elliptic figure. There are three species, natives of the West Indies. The A. tomentose is a tree about 15 feet high, agreeing in many respects with the mangrove.

AVIS, bird, *aves*, among naturalists, the second class of animals, a race of creatures sufficiently distinguished from others in having the body covered with feathers, two feet, and two wings formed for flight. Birds have the mandible protracted and naked; and are destitute of external ears, lips, teeth, scrotum, womb, urinary vessel, or bladder, epiglottis, corpus callosum, or its fornix, and diaphragm. In the Linnæan system birds are divided into six orders, *viz.* accipitres, or falcon kind, picæ, or pies, anseres, or geese and duck kind, grallæ, cranes or waders, gallinæ, the poultry kind, and passeres, sparrows or small birds.

Avis is also the name of an order of knighthood in Portugal, instituted by Sancho the first king, in imitation of the order of Alcantara, whose great cross they wear.

AVISANDUM, in Scotch law, literally signifies advising, or under consideration. A process is said to be under avisandum, when the whole proofs, with the arguments on both sides, are under the consideration of the judge, before he has given an interlocutor or decision upon the cause.

AVISO, *adviso*, Ital. a term chiefly used in matters of commerce, to denote an advertisement, an advice, or a piece of intelligence.

AULIC, an epithet given to certain officers of the Germanic empire, who compose a court, which decides, without appeal, in all processes entered in it.

The aulic council is composed of a president, who is a catholic; of a vice chancellor, presented by the archbishop of Mentz; and of eighteen counsellors, nine of whom are protestants, and nine catholics. They are considered as a bench of lawyers, and always follow the emperor's court; for which reason they are called justitium imperatoris, the emperor's justice, and aulic council. The aulic court ceases at the death of the emperor; whereas the imperial chamber of Spire is perpetual, representing not only the deceased emperor, but the whole Germanic body, which is reputed never to die.

Aulic, in the Sorbonne and foreign universities, is an act which a young divine maintains upon being admitted a doctor in divinity.

It begins by an harangue of the chancellor, addressed to the young doctor; after which he receives the cap, and presides at the aulic, or disputation.

AUME, a Dutch measure for Rhenish wine, containing forty English gallons.

AUMONE, in law, signifies a tenure where lands are given in alms to some church or religious house.

AUNCEL weight, an ancient kind of balance, now out of use, being prohibited by several statutes, on account of the many deceits practised by it. It consisted of scales hanging on hooks, fastened at each end of a beam, which a man lifted up on his hand. In many parts of England auncel weight signifies meat sold by the hand, without scales.

AUNE, a long measure used in France to measure cloth, stuffs, ribands, &c.

At Rouen it is equal to one English ell, at Calais to 1.52, at Lyons to 1.016, and at Paris to 0.95.

AVOCATORIA, a mandate of the emperor of Germany, addressed to some prince in order to stop his unlawful proceedings in any cause appealed to him.

AVOIDANCE, in the canon law, is when a benefice becomes void of an incumbent: which happens either in fact, as by the death of the parson; or in law, as by cession, deprivation, resignation, &c. In the first of these cases, the patron must take notice of the avoidance, at his peril; but in avoidance by law, the ordinary is obliged to give notice to the patron, in order to prevent a lapse.

AVOIRDUPOIS *weight*, a kind of weight used in England, of which the pound weighs 16 ounces. The proportion of a pound avoirdupois to a pound troy, is as 17 to 14: or the avoirdupois pound contains 7000 grains and the troy pound 5760.

All the larger and coarser commodities are weighed by avoirdupois weight; as groceries, cheese, wool, lead, hops, &c.

AVOWRY, in law, is where a person distrained sues out a replevin; for then the distrainer must avow and justify his plea, which is called his avowry. The avowry must contain sufficient matter for judgment to have return, but so much certainty is not required as in a declaration; and if made for rent, though it appears that part of that rent is not due, yet the avowry is good for the rest.

AURANTIUM, the orange tree. See Citrus.

AURANTII *cortex*. See Pharmacy.

AUREA *Alexandrina*, in pharmacy, a kind of opiate, or antidote against the colic and apoplexy, composed of a great number of ingredients, which was in great fame among the ancient writers. It is called aurea from the gold, aurum, which is an ingredient in its composition; and Alexandrina, as having been invented by a physician named Alexander.

AURELIA. See Chrysalis.

AUREOLA, in its original signification, signifies a jewel which is proposed as a reward of victory, in some public dispute. Hence the Roman schoolmen applied it to denote the reward bestowed on martyrs, virgins, and doctors, on account of their works of supererogation: and painters use it to signify the crown of glory, with which they adorn the heads of saints, confessors, &c.

AUREUS, a Roman gold coin, equal in value to twenty-five denarii.

According to Ainsworth, the aurens of the higher empire weighed near five pennyweights, and in the lower empire little more than half that weight.

AURICHALCUM. See Orichalcum.

AURICLE, in anatomy, that part of the ear which is prominent from the head, called by many authors auris externa. See the article Ear. Also the appendages of the heart at its base, which are distinguished by the names of the right and left.

AURICULA. See Primula.

AURIFLAMMA, in the French history, a standard belonging to the abbey of St. Dennis, suspended over the tomb of that saint, which the religious, on occasion of any war in defence of their lands or rights, took down with great ceremony, and gave it to their protector or advocate, to be borne at the head of their forces. Hence the word is sometimes used to denote the chief flag or standard of an army.

AURIGA, the WAGGONER, in astronomy, a constellation of the northern hemisphere, consisting of twenty-seven stars according to Tycho, forty according to Hevelius, and sixty-six in the Britannic catalogue.

This is one of the forty-eight asterisms mentioned by all ancient astronomers; and represented by the figure of an old man in a kind of sitting posture, with a goat and her kids in his left hand, and a bridle in his right. Besides the hœdi, this constellation includes another star, called capella; which is the bright one near the shoulder, and supposed to be the mother of the hœdi, and the nurse of Jupiter. The hœdi, or the two stars in the arm of Auriga, were regarded by the ancients as affording presages of the weather; and these were so much dreaded on account of the storms and tempests that succeeded their rising, that they are said to have shut up the navigation at this season.

AURIUM *abscissio*, in antiquity, cutting off ears, was a punishment inflicted by the Saxon law on those who robbed churches, and afterward on every thief, and at length on other criminals.

AURORA BOREALIS, *northern light*, or *streamers*, a kind of meteor appearing in the northern part of the heavens, mostly in the winter season, and in frosty weather. It is usually of a reddish colour, inclining to yellow; and sends out frequent corruscations of pale light, which seem to rise from the horizon in a pyramidal undulating form, and shooting with great velocity up to the zenith. It appears often in form of an arch, which is partly bright, and partly dark, but generally transparent: and the matter of it is not found to have any effect on the rays of light, which pass freely through it. Dr. Hamilton observes that he could plainly discern the smallest speck in the Pleiades through the density of those clouds which formed part of the aurora borealis in 1763, without the least diminution of its splendour, or increase of twinkling. Philos. Essays, p. 106.

Sometimes it produces an iris. Hence M. Godin judges that most of the extraordinary meteors and phenomena in the skies, related as prodigies by historians, as battles, and the like, may probably enough be reduced to the class of auroræ boreales. Hist. Acad. R. Scien. for 1762, p. 405.

This kind of meteor never appears near the equator; but, it seems, is as frequent toward the south pole as toward the north, having been observed there by voyagers. See Philos. Trans. No. 461, and vol. 54; also Forster's Account of his Voyage round the World with Capt. Cook, in which he describes their appearance as observed for several nights together in sharp frosty weather; which was much the same as those seen in the north, excepting that they were of a lighter colour.

It seems that meteors of this kind have appeared at some times more frequently than at others. They were so rare in England, or else so little regarded, that none are recorded in our annals since that remarkable one of November 14, 1574, till the surprising aurora borealis of March 6, 1716, which appeared for three nights successively, but by far more strongly on the first; except that five small ones were observed in the years 1707 and 1708. Hence it would seem that the air or earth, or both, are not at all times disposed to produce this phenomenon.

The extent of these appearances is also amazingly great. That in March, 1716, was visible from the west of Ireland to the confines of Russia and the east of Poland, extending at least near 30 degrees of longitude, and from about the 50th degree in latitude over almost all the north of Europe: and in all places, at the same time, it exhibited the like wondrous appearances.

Father Boscovich has determined the height of an aurora borealis, which was observed by the marquis of Polini the 16th of December, 1737, and found it was 825 miles high; and Mr. Bergmann, from a mean of 30 computations, makes the average height of the aurora borealis amount to 70 Swedish, or 469 English, miles. But Euler supposes the height to be several thousands of miles; and Mairan also assigns to them a very elevated region.

In Sweden and Lapland the auroræ boreales are not only singularly beautiful, but afford travellers, by their almost constant effulgence, a very fine and brilliant light during the whole night. In Hudson's bay, the light of the aurora borealis is said to be equal to that of a full moon: and in the northeastern parts of Siberia, we are told, these northern lights are observed to begin with single bright pillars, rising in the north, and almost at the same time in the northeast, which, gradually increasing, comprehend a large space of the heavens, rush about from place to place with incredible velocity, and finally almost cover the whole sky up to the zenith, and produce an appearance in the heavens of a vast expanded tent, glittering with gold, rubies and sapphire. A more interesting spectacle cannot be conceived; but whoever sees such a northern light for the first time could not behold it without terror. For however fine the illumination may be, it is attended, as it is said, with a hissing noise through the air, as if the largest fireworks were playing off. To describe what they then hear, the natives make use of the expression *spolochi chodjat*, that is, the raging host is passing. The hunters who pursue the foxes are frequently overtaken with these lights; and their dogs are then so much terrified, that they will not move, but lie obstinately on the ground till the noise is passed. See Philos. Trans. vol. lxxiv.

Many attempts have been made to determine the cause of this phenomenon. Dr. Halley imagines that the watery vapours or effluvia, exceedingly rarefied by subterraneous fire, and tinged with sulphureous streams, which many naturalists have supposed to be the cause of earthquakes, may also be the cause of this appearance; or that it is produced by a kind of subtile matter freely pervading the pores of the earth, and which, entering into it nearer the southern pole, passes out again with some force into the ether, at the same distance from the northern. This subtile matter, by becoming more dense, or having its velocity increased, may perhaps be capable of producing a small degree of light, after the manner of effluvia from electric bodies, which, by a strong and quick friction, emit light in the dark; to which sort of light this seems to have a great affinity. Philos. Trans. No. 347. See also

Mr. Cotes's description of this phenomenon, and his method of explaining it by streams emitted from the heterogeneous and fermenting vapours of the atmosphere, in Smith's Optics, p. 69; or Philos. Trans. abr. vol. 6, part 2.

Ever since the identity of lightning and the electric matter has been determined, however, philosophers have been naturally led to seek for the explication of aerial meteors in the principles of electricity; and there is now no doubt that most of them, and especially the aurora borealis, are electrical phenomena. Besides the more obvious and known appearances which constitute a resemblance between this meteor and the electric matter by which lightning is produced, it has been observed, that the aurora occasions a very sensible fluctuation in the magnetic needle; and that when it has extended lower than usual in the atmosphere, the flashes have been attended with various sounds of rumbling and hissing, especially in Russia and the other more northern parts of Europe, as noticed by Sig. Beccaria and M. Messier. Mr. Canton, soon after he had obtained electricity from the clouds, offered a conjecture that the aurora is occasioned by the dashing of electric fire positive toward negative clouds at a great distance, through the upper part of the atmosphere, where the resistance is least: and he supposes that the aurora which happens at the time when the magnetic needle is disturbed by the heat of the earth, is the electricity of the heated air above it: and this appears chiefly in the northern regions, as the alteration in the heat of the air in those parts is the greatest. Nor is this hypothesis wholly improbable, when it is considered that electricity is the cause of thunder and lightning; that it has been extracted from the air at the time of the aurora borealis; that the inhabitants of the northern countries observe it remarkably strong when a sudden thaw succeeds very cold severe weather; and that the tourmalin is known to emit and absorb the electric fluid only by the increase or diminution of its heat. Positive and negative electricity in the air, with a proper quantity of moisture to serve as a conductor, will account for this and other meteors sometimes seen in a serene sky. Mr. Canton afterward contrived to exhibit this meteor by means of the Torricellian vacuum, in a glass tube about three feet long, and sealed hermetically. When one end of the tube is held in the hand, and the other applied to the conductor, the whole tube will be illuminated from end to end, and will continue luminous without interruption for a considerable time after it has been removed from the conductor. If, after this, it is drawn through the hand either way, the light will be remarkably intense through the whole length of the tube. And, though a great part of the electricity is discharged by this operation, it will still flash at intervals, when held only at one extremity, and kept quite still; but if, at the same time, it is grasped by the other hand in a different place, strong flashes of light will dart from one end to the other; and these will continue 24 hours or more, without a fresh excitation. Sig. Beccaria conjectures that there is a constant and regular circulation of the electric fluid from north to south; and he thinks that the aurora borealis may be this electric matter performing its circulation in such a state of the atmosphere as renders it visible, or approaching nearer than usual to the earth: though probably this is not the mode of its operation, as the meteor is observed in the southern hemisphere with the same appearances as in the northern. Dr. Franklin supposes that the electric fire discharged into the polar regions, from many leagues of vaporized air raised from the ocean between the tropics, accounts for the aurora borealis; and that it appears first where it is first in motion, namely, in the most northern part; and the appearance proceeds southward, though the fire really moves northward. Franklin's Exper. and Obs. 1769, p. 49; Philos. Trans. vol. lviii. p. 358, 784; *Ib.* vol. li. p. 403; Lettere dell' Ellettricismo, p. 269; or Priestley's Hist. of Electricity.

Mr. Dalton, who has paid considerable attention to meteorology, gives the following account of the appearances of the aurora borealis: They come under four different descriptions. 1. A horizontal light, like the break of day. 2. Fine slender luminous beams, well defined, and of dense light, which often continue nearly a minute at rest. 3. Flashes pointing upward, or in the direction of the beams which they succeed. These are only momentary, and have no lateral motion. They appear broad and diffuse, and of a weaker light than the beams; they grow gradually fainter till they disappear, and continue for hours flashing at intervals. 4. Arcs nearly in the form of a rainbow: these when complete go quite across the heavens, from one point of the horizon to the opposite point. These appearances generally succeed each other in the following order: 1. the faint rainbow like arcs; 2. the beams; and, 3. the flashes. The northern horizontal light appears to consist of an abundance of flashes or beams blended together by the situation of the observer. The beams of the aurora appear at all places to be arcs of great circles of the sphere, with the eye in the centre; and these arcs, if prolonged upward, would all meet in a point. The rainbow like arcs cross the magnetic meridian at right angles. When two or more appear at once, they are concentric, and tend to the east and west: also the broad arc of the horizontal light tends to the magnetic east and west, and is bisected by the magnetic meridian: and when the aurora extends over any part of the hemisphere, the line separating the illuminated part of the hemisphere from the clear part is half the circumference of a great circle crossing the magnetic meridian at right angles, and terminating in the east and west. That point in the heavens to which the beams of the aurora appear to converge, at any place, is the same as that to which the south pole of the dipping needle points at that place. The beams appear to rise above each other in succession; so that of any two beams, that which has the higher base has also the higher summit. Every beam appears broadest at or near the base, and to grow narrower as it ascends; so that the continuation of the bounding lines would meet in the common centre to which the beam tends. The height of the rainbow like arcs of the aurora borealis is estimated by Mr. Dalton to be 150 miles above the earth's surface.

AURUM, gold. Gold seems to have been known from the very beginning of the world. Its properties and its scarcity have rendered it more valuable than any other metal.

It is of an orange red or reddish yellow colour, and has no perceptible taste or smell. Its lustre is considerable, yielding only to that of platinum, steel, silver, and mercu-

ry. Its specific gravity 19.3. No other substance is equal to it in ductility and malleability. It may be beaten out into leaves so thin that one grain of gold will cover $56\frac{3}{4}$ square inches. These leaves are only 1-282000th of an inch thick, but the gold leaf with which silver wire is covered has only 1-12th of that thickness. An ounce of gold, upon silver wire, is capable of being extended more than 1300 miles in length. Its tenacity is considerable, though in this respect it yields to iron, copper, platinum, and silver. From the experiments of Sickingen it appears that a gold wire 0.078 inch in diameter is capable of supporting a weight of 150.07lbs. avoirdupois, without breaking. It melts at 32° of Wedgewood's pyrometer. When melted, it assumes a bright bluish green colour. It expands in the act of fusion, and consequently contracts while becoming solid more than most metals; a circumstance which renders it less proper for casting into moulds. It requires a very violent heat to volatilize it; it is, therefore, to use a chymical term, exceedingly *fixed*. Boyle and Kunkel kept it for some months in a glasshouse furnace, and yet it underwent no change; nor did it lose any perceptible weight, after being exposed for some hours to the utmost heat of Mr. Parker's lens. Homberg, however, observed, that when a very small portion of gold is kept in fusion, part of it is volatilized. This observation was confirmed by Macquer; who observed the metal rising in fumes to the height of five or six inches, and attaching itself to a plate of silver, which it gilded very accurately; and Mr. Lavoisier observed the very same thing when a piece of silver was held over gold melted by fire blown by oxygen gas, which produces a much greater heat than common air. After fusion, it is capable of assuming a crystaline form.

Gold is not in the least altered by being kept exposed to the air; it does not even lose its lustre; neither has water the smallest action upon it. It is capable, however, of combining with oxygen, and even of undergoing combustion in particular circumstances. The resulting compound is an oxide of gold. There are two oxides of gold; the protoxide is of a purple or violet, the peroxide of a yellow colour.

Gold must be raised to a very high temperature before it is capable of abstracting oxygen from common air. It may be kept red hot almost any length of time without any such change. Homberg, however, observed, that when placed in the focus of Tschirnhausen's burning glass, its surface became covered with a purple coloured oxide; and the truth of his observations were put beyond doubt by the subsequent experiments of Macquer with a still more powerful burning glass. It was remarked also in 1773 by Camus, that when the electric explosion is transmitted through gold leaf placed between two plates of glass, or when a strong charge is made to fall on a gilded surface; in both cases the metal is oxidized, and assumes a purple colour. The reality of the oxidizement of gold by electricity was disputed by some philosophers, but it has been put beyond the reach of doubt by the experiments of Van Marum. When that celebrated philosopher made electric sparks from the powerful Teylerian machine pass through a gold wire suspended in the air, it took fire, burnt with a green coloured flame, and was completely dissipated in fume, which when collected proved to be a purple coloured oxide of gold. This combustion, according to Van Marum, succeeded not only in common air, but also when the wire was suspended in hydrogen gas and other gases which are not capable of supporting combustion. These singular observations would require to be verified by other experiments before any conclusion can be drawn from them. The combustion of gold is now easily effected by exposing gold leaf to the action of the galvanic pile. It has been made to burn with great brilliancy by exposing a gold wire to the action of a stream of oxygen and hydrogen gas mixed together and burning. In all cases of the combustion of gold, it has been ascertained, that the protoxide or purple coloured oxide only is formed. The peroxide, or yellow coloured oxide, may be procured in the following manner: Equal parts of nitric and muriatic acids are mixed together, and poured upon gold; an effervescence takes place, the gold is gradually dissolved, and the liquid assumes a yellow colour. It is easy to see in what manner this solution is produced. No metal is soluble in acids till it has been reduced to the state of an oxide. There is a strong affinity between the oxide of gold and muriatic acid. The nitric acid furnishes oxygen to the gold, and the muriatic dissolves the oxide as it forms. When nitric acid is deprived of the greater part of its oxygen, it assumes a gaseous form, and is then called nitrous gas, or more properly nitric oxide gas. It is the emission of this gas which causes the effervescence. The oxide of gold may be precipitated from the nitro muriatic acid, by pouring in a little potash dissolved in water, or, which is much better, a little lime; both of which have a stronger affinity for muriatic acid than the oxide has.

The oxides of gold may be decomposed in close vessels by the application of heat. The gold remains fixed, and the oxygen assumes the gaseous form. They may be decomposed, too, by all the substances which have a stronger affinity for oxygen than gold has.

Hitherto gold has not been found capable of combining with sulphur, carbon, or hydrogen. M. Pelletier combined it with phosphorus, by melting together in a crucible half an ounce of gold and an ounce of phosphoric glass, surrounded with charcoal. The phosphuret of gold thus produced was brittle, whiter than gold, and had a crystalized appearance. It was composed of 23 parts of gold and one of phosphorus. He formed the same compound by dropping small pieces of phosphorus into gold in fusion. Phosphorus, then, is the only one of the simple combustibles with which gold at present is supposed capable of combining.

Neither does gold combine, as far as is known, with either of the simple incombustible bodies. But gold combines readily with the greater number of the metals, and forms a variety of alloys.

The affinities of gold and its oxides are placed by Bergmann in the following order:

Gold.	*Oxide of Gold.*
Mercury,	Muriatic acid,
Copper,	Nitric,
Silver,	Sulphuric,
Lead,	Arsenic.
Bismuth,	Fluoric,

Gold.	*Oxide of Gold.*
Tin,	Tartaric,
Antimony,	Phosphoric,
Iron,	Prussic.
Platinum,	
Zinc,	
Nickel,	
Arsenic,	
Cobalt,	
Manganese.	

AURUM, *fulminans*. See CHYMISTRY.

AURUM *potabile*, potable gold, a liquid preparation of this metal, formerly much used in medicine.

AUSCULTARE, in ancient customs. A person was formerly appointed to instruct the monks to read and sing before they were allowed to perform in public. This was called *auscultare*, to *hear* or *listen*.

AUSPICIUM. See AUGURY.

AUSTRALIS *Piscis*, a constellation of the southern hemisphere, not visible in our latitude. The stars in Ptolemy's catalogue are 18, and in the Britannic 24. The star Fomahaut, of the first magnitude, is in the mouth of the fish.

AUTER *droit*, in law, is when persons sue or are sued in another's right, as executors, guardians, &c.

AUTER *fois acquit*, in law, a plea made by a criminal that he has been already acquitted of the same crime with which he is charged. For no man shall be arraigned more than once for the same offence.

AUTHENTIC, in the civil law, a name given to the novels of Justinian, in which *authenticating* is a term used for punishing an adulteress by public whipping and imprisonment for two years; then, if her husband refuses to take her back, she is shaven, veiled, and shut up for life.

AUTHORITY, in law, a power given by word or writing to a second person to transact something, and may be by writ, warrant, commission, letter of attorney, &c. and sometimes by law. An authority given to another to do what a person himself cannot do is void; and it must be for doing a thing that is lawful, otherwise it will be no good authority.

AUTO *da fe*. See ACT OF FAITH.

AUTOMATON, a seemingly self moving machine; or one so constructed, by means of weights, levers, pulleys, springs, &c. as to move for a considerable time as if it was endued with animal life: and according to this description, clocks, watches, and all machines of that kind, are automata.

It is said that Archytas of Tarentum, 400 years before Christ, made a wooden pigeon that could fly; that Archimedes also made such automatons; that Regiomontanus made a wooden eagle that flew forth from the city, met the emperor, saluted him, and returned; also that he made an iron fly, which flew out of his hand at a feast, and returned again after flying about the room; that Dr. Hook made the model of a flying chariot, capable of supporting itself in the air. Many other surprising automatons we have been eye witnesses of in the present age: thus, we have seen figures that could write, and perform many other actions in imitation of animals. M. Vaucanson made a figure that played on the flute: the same gentleman also made a duck which was capable of eating, drinking, and imitating exactly the voice of a natural one; and, what is still more surprising, the food it swallowed was evacuated in a digested state, or considerably altered on the principles of solution; also the wings, viscera, and bones, were formed so as strongly to resemble those of a living duck; and the actions of eating and drinking showed the strongest resemblance, even to the muddling the water with its bill. M. Le Droz, of La Chaux de Fonds, in the province of Neufchatel, has also executed some very curious pieces of mechanism: one was a clock, presented to the king of Spain, which had, among other curiosities, a sheep that imitated the bleating of a natural one, and a dog watching a basket of fruit, that barked and snarled when any one offered to take it away; besides a variety of human figures, exhibiting motions truly surprising.

Another automaton of Droz's was the figure of a man, about the natural size, which held in the hand a metal style, and by touching a spring that released the internal clockwork from its stop, the figure began to draw on a card; and having finished its drawings on the first card, the figure rested, and then proceeded to draw different subjects on five or six other cards. The first card exhibited elegant portraits of the king and queen facing each other; and the figure was observed to lift its pencil with the greatest precision, in the transition from one point to another, without making the least slur.

AUTOUR, in natural history, a sort of bark which resembles cinnamon, but is paler and thicker; it is the colour of a broken nutmeg, and full of spangles. It comes from the Levant, and is an ingredient in the carmine dye.

AUTUMNAL *signs*, in astronomy, are the signs Libra, Scorpio, and Sagittarius, through which the Sun passes during the autumn.

AUXILIARY *verbs*, in grammar, are such as help to form or conjugate others; that is, are prefixed to them, to form or denote the moods or tenses thereof: as *to have* and *to be*.

In the English language the auxiliary verb *am* supplies the want of passive verbs.

AUXILIUM *ad filium militem faciendum, vel filiam maritandam*, a precept or writ directed to the sheriff of every county where the king or other lords had any tenants, to levy of them reasonable aid toward the knighting his eldest son, or the marriage of his eldest daughter.

AWARD, in law, the judgment of an arbitrator for terminating a difference.

AWK. See ALCA.

AXILLA, in anatomy, the armpit, or the cavity under the upper part of the arm.

AXILLA, in botany, the space comprehended betwixt the stems of plants and their leaves.

AXIOM, in philosophy, is such a plain, self evident, and received notion, that it cannot be made more plain and evident by demonstration, because it is itself better known than any thing that can be brought to prove it: as, that nothing can act where it is not; that a thing cannot be and not be at the same time; that the whole is greater than a part thereof; and that from nothing nothing can arise.

AXIS, in geometry, the straight line in a plane figure, about which it revolves, to produce or generate a solid: thus, if a semicircle be moved round its diameter at rest, it will generate a sphere, the axis of which is that diameter.

Axis, in astronomy. 1. Axis of the world, an imaginary right line conceived to pass through the centre of the earth from one pole to the other, about which the sphere of the world, in the Ptolemaic system, revolves in its diurnal rotation. 2. The axis of a planet is that line drawn through the centre about which the planet revolves. The Sun, together with all planets, except Mercury and Saturn, are known by observation to move about their respective axes. The axis of the Earth, during its revolution round the Sun, remains always parallel to itself; and is inclined to the plane of the ecliptic, making with it an angle of 66½ degrees. 3. The axes of the equator, horizon, ecliptic, zodiac, &c. are right lines drawn through the centres of those circles perpendicular to their planes. See Astronomy.

Axis, in conic sections, a right line dividing the section into two equal parts, and cutting all its ordinates at right angles. See Conic Sections.

The axis of the parabola is of an indeterminate length. The axis of the ellipsis is determinate. In the ellipsis and hyperbola, there are two axes and no more; and in the parabola only one.

Axis, in mechanics. The axis of a balance is that line about which it moves, or rather turns. Axis of oscillation is a right line parallel to the horizon, passing through the centre, about which a pendulum vibrates. See Mechanics.

Axis *in peritrochio*, one of the five mechanical powers, consisting of a peritrochium or wheel, and moveable together with it about its axis. The power is applied at the circumference of the wheel, and the weight is raised by a rope that is gathered up on the axis while the machine turns round. The power may be conceived as applied at the extremity of the arm of a lever, equal to the radius of the wheel; and the weight as applied at the extremity of a lever, equal to the radius of the axis; only those arms do not meet at one centre of motion, as in the lever; but in place of this centre, we have an axis of motion, *viz.* the axis of the whole machine. See Mechanics.

The use of this machine is to raise weights to a greater height than the lever can do, because the wheel is capable of being turned several times round, which the lever is not; and also to communicate motion from one part of a machine to another. Accordingly, there are few compound machines without it.

Axis, in optics, is that ray among all others that are sent to the eye, which falls perpendicularly upon it, and which consequently passes through the centre of the eye. Common or mean axis is a right line drawn from the point of concourse of the two optic nerves through the middle of the right line, which joins the extremity of the same optic nerves. Axis of a glass or lens, is a right line joining the middle points of the two opposite surfaces of the glass.

Axis of incidence, in dioptrics, is a right line perpendicular in the point of incidence to the refracting superficies, drawn in the same medium that the ray of incidence comes from.

Axis of refraction, is a right line drawn through the refracting medium, from the point of refraction, perpendicular to the refracting superficies.

Axis, in architecture. Spiral axis is the axis of a twisted column drawn spirally in order to trace the circumvolutions without. Axis of the Ionic capital, is a line passing perpendicularly through the middle of the eye of the volute.

Axis of a vessel, is an imaginary right line passing through the middle of it perpendicularly to its base, and equally distant from its sides.

Axis of a magnet, is a line passing through the middle of a magnet lengthwise in such a manner as that, however the magnet is divided, provided the division is made according to a plane in which such line is found, the magnet will be cut or separated into two loadstones; and the extremes of such lines are called the poles of the magnet.

Axis, in anatomy, the second vertebra of the neck, so called from the head's turning on it like an axis.

Axis, in zoology, an animal of the deer kind. See Cervus.

AXYRIS, in botany, a genus of the triandria order, belonging to the monoecia class of plants, and in the natural method ranking under the twelfth order, holoraceæ. The calyx of the male is tripartite; it has no corolla. The calyx of the female consists of two leaves; it has two styli and one seed. There are three species, all annual, and natives of Siberia.

AYE-AYE, in zoology, a singular quadruped discovered in Madagascar. Its name is an exclamation of the inhabitants, which M. Sonnerat applied to this animal. Both male and female are slothful and gentle animals; and, like owls, they are scarcely able to discern objects in the day time. They live chiefly under ground, feeding on worms and insects which they find in the earth or in crevices in the trunks of trees, whence they extract them by means of their long and slender toe. Sonnini forms a new genus of this animal, the generic character of which is the long toes, the thumb of the hinder pair being turned backward.

AYENIA, in botany, a genus of the pentandria order, belonging to the gynandria class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx has two leaves; the petals are in the form of a star, with long ungues; and the capsule has five cells. There are four species, all natives of the West Indies.

AZAB, in the Turkish armies, a distinct body of soldiery, who are great rivals of the Janizaries.

AZALEA, an American upright honeysuckle, a genus of the monogynia order, and pentandria class of plants; and in the natural method ranking under the 18th order, bicornes. The corolla is bell shaped; the stamina are inserted into the receptacle, and the capsule has 5 cells. There are 7 species, of which the most remarkable are the following:

1. Azalea nudiflora, or red American upright honeysuckle, grows taller than the viscosa, and in its native country will sometimes arrive at the height of 12 feet, but in Britain never rises to above half that height. It has several stems with oblong smooth leaves. The flower stalks arise from the division of the branches, which are long and naked, supporting a cluster of red flowers: these are divided at the top into 5 equal segments, which spread open.

2. Azalea viscosa, with a white flower, is a low shrub, arising with several stems to the height of two or three feet. The leaves come out in clusters without any order

at the end of the shoots, and their edges are set with very short teeth, which are rough. The flowers come out in clusters between the leaves, have much the appearance of honeysuckle, and are as well scented.

3. Azalea Pontica, a native of Pontus, has large and beautiful yellow flowers, very fragrant.

Of the nudiflora there are also some beautiful varieties, particularly the scarlet and the orange. In short, there has not been a greater accession to our gardens than these truly elegant shrubs. They will only thrive in bog earth, and are chiefly propagated by layers, as the finer roots seldom ripen seeds in England. They must be removed with a clump of earth, as disturbing the fibres destroys them.

AZIMUTH, in astronomy, an arch of the horizon, intercepted between the meridian of the place and the azimuth, or vertical circle passing through the centre of the object, which is equal to the angle of the zenith formed by the meridian and vertical circle; or it is found by this proportion; as the radius, to the tangent of the latitude of the place, so is the tangent of the sun's or star's altitude, for instance, to the cosine of the azimuth from the south, at the time of the equinox. To find the azimuth by the globe, see the article GLOBE.

AZIMUTH, *magnetical*, an arch of the horizon intercepted between the azimuth, or vertical circle passing through the centre of any heavenly body, and the magnetical meridian. This is found by observing the object with an azimuth compass.

AZIMUTH *compass*, an instrument adapted to find, in a more accurate manner than by the common sea compass, the sun's or star's magnetical amplitude, or azimuth.

AZIMUTH, *dial*, one whose style or gnomon is at right angles to the plane of the horizon.

AZIMUTH *circles*, called azimuths, or vertical circles, are great circles of the sphere, intersecting each other in the zenith and nadir, and cutting the horizon at right angles in all the points thereof. The horizon being divided into 360°, they usually conceive 360 azimuths. These azimuths are represented by the rhumbs on common sea charts, and on the globe they are represented by the quadrant of altitude when screwed in the zenith. On these azimuths is reckoned the height of the stars, and of the sun, when not in the meridian.

AZOGA SHIPS, Spanish ships, commonly called the quicksilver ships, from their carrying quicksilver to the Spanish West Indies, in order to extract the silver out of the mines of Mexico and Peru. These ships, strictly speaking, are not to carry any goods, unless for the king of Spain's account; but by procuring special licenses, they are enabled to take in a full cargo for merchants, as well as the sovereign.

AZOLLA CAROLINIANA, in botany, a species of the cryptogamia, hepaticæ, class and order. (*a*)

AZOOPHAGUS, a term used by authors to express such animals and insects as never eat the flesh of any creature that has had life.

AZOTE, or *nitrogen*, in chymistry, a substance hitherto considered as elementary, existing abundantly in nature, forming full three fourths of the atmosphere. It is a peculiar and almost characteristic ingredient of animal matter, the basis of nitric acid, and one of the constituents of volatile alkali. Pure azote is known only in the form of gas; it is then synonymous with the phlogisticated air of Scheele and Priestley, the atmospherical mephitis of Lavoisier, and the nitrogen gas of Chaptal.

Azote may be procured by the following processes. If a quantity of iron filings and sulphur, mixed together, and moistened with water, is put into a glass vessel full of air, it will absorb all the oxygen in the course of a few days; but a considerable residuum of air will still remain incapable of any further diminution. This residuum has obtained the appellation of azotic gas. There are other methods of obtaining it more speedily. If phosphorus, for instance, is substituted for the iron filings and sulphur, the absorption is completed in less than 24 hours. The following method, first pointed out by Berthollet, furnishes very pure azotic gas, if the proper precautions are attended to. Very much diluted aquafortis, or nitrous acid, as it is called in chymistry, is poured upon a piece of muscular flesh, and a heat of about 100° applied. A considerable quantity of azotic gas is emitted, which may be received in proper vessels.

The air of the atmosphere contains about 0.78 parts, in bulk, of azotic gas; almost all the rest of it is oxygen gas. Mr. Lavoisier was the first philosopher who published this analysis, and who made azotic gas known as a component part of air. His experiments were published in 1774, or perhaps rather 1775. Scheele undoubtedly was acquainted as early with the composition of air; but his Treatise on Fire, in which that analysis is contained, was not published till 1777.

Mr. Kirwan examined the specific gravity of azotic gas obtained by Scheele's process; it was 0.00120; it is therefore somewhat lighter than atmospheric air; it is to atmospheric air as 985 to 1000. According to the experiments of Lavoisier, its specific gravity is only 0.00115, or it is to common air as 942.6 to 1000.

This gas is invisible and elastic, like common air; and like it too, capable of indefinite condensation and dilation. It is exceedingly noxious to animals; if obliged to respire it, they drop down dead almost instantly. No combustible will burn in it. Hence the reason why a candle is extinguished in atmospherical air as soon as the oxygen near it is consumed.

Azotic gas is capable of combining with oxygen. Take a glass tube, the diameter of which is about the sixth part of an inch; shut one of its ends with a cork, through the middle of which passes a small wire with a ball of metal at each end. Fill the tube with mercury, and then plunge its open end into a basin of that fluid. Throw up into the tube as much of a mixture, composed of 13 parts of azotic and 87 parts of oxygen gas, as will fill three inches. Through this gas make, by means of the wire in the cork, a number of electric explosions pass. The volume of gas gradually diminishes, and in its place there is found a quantity of nitric acid. This acid, therefore, is composed of azote and oxygen; and these two substances are capable of combining; or, which is the same thing, azotic gas is capable of combustion in the temperature produced by electricity, which we know to be high. The combination of azotic gas with oxygen, and the nature of the product were discovered by Mr. Cavendish, and communicated to the Royal Society on the 2d of June, 1785.

When sulphur is melted in azotic gas, part of it is dissolved, and sulphureted azotic gas formed. This gas has a fetid odour. Its properties are still unknown.

Phosphorus plunged into azotic gas is dissolved in a small proportion. Its bulk is increased about 1-40th, and phosphureted azotic gas is the result. When this gas is mixed with oxygen gas, it becomes luminous, in consequence of the combustion of the dissolved phosphorus. The combustion is most rapid when bubbles of phosphureted azotic gas are let up into a jar full of oxygen gas. When phosphureted oxygen gas and phosphureted azotic gas are mixed together, no light is produced, even at the temperature of 82°.

Azotic gas dissolves also a little carbon; for azotic gas obtained from animal substances, by Berthollet's process, when confined long in jars, deposites on the sides of them a black matter, which has the properties of charcoal.

When mixed with hydrogen gas, it undergoes no change. It may, however, be combined with hydrogen, and the compound formed is known by the name of ammonia or volatile alkali.

The affinities of azote are still unknown. It has never yet been decompounded; and must therefore, in the present state of our knowledge, be considered as a simple substance. See Air.

AZURE, in heraldry, the blue colour in the arms of any person below the rank of a baron. In the escutcheon of a nobleman, it is called sapphire; and in that of a sovereign prince, Jupiter. In engraving, this colour is expressed by lines or strokes drawn horizontally.

AZYGOS, in anatomy, a vein rising within the thorax on the right side, having no fellow on the left: whence it is called azygos, or vena sine pari.

AZYMITES, in church history, Christians who administer the eucharist with unleavened bread.

AZYMOUS, something unfermented; as bread, &c. made without leaven. This term has occasioned frequent disputes, and, at length, a rupture between the Latin and the Greek churches; the former of which maintain, that the bread in the mass ought to be azymous, unleavened, in imitation of the paschal bread of the Jews, and of our Saviour, who instituted the sacrament on the day of the passover. The latter as strenuously maintain the contrary, from tradition and the common usage of the church.

B.

B, the second letter of the alphabet, is used as an abbreviation: in music, B stands for the tone above A: B also stands for bass, and B.C. for basso continuo, or thorough bass. As a numeral, B was used by the Greeks and Hebrews to denote 2: but among the Romans, for 300, and with a dash over it (thus, $\overline{B}$) for 3000. The same people likewise used B. for Brutus, B. F. for bonum factum. B, in the old chymical alphabet, signifies Mercury; B.A. stands for bachelor of arts; B.L. for bachelor of laws; and B.D. for bachelor of divinity.

BABOON, in zoology. See Simia.

BABYLONICA, *texta*, a rich sort of weavings, or hangings, so denominated from the city of Babylon, where the practice of interweaving divers colours in their hangings was first invented.

BACA, in botany. See Berry.

BACCHÆ, in antiquity, priestesses of the god Bacchus. They were likewise called mænades, on account of the frantic ceremonies used in their feasts; as also thyades, which signifies impetuous, or furious.

BACCHANALIA, feasts celebrated in honour of Bacchus by the ancient Greeks and Romans; of which the two most remarkable were called the greater and lesser. The latter were held in the open fields about autumn; but the greater, called dionysia, were celebrated in the city in spring time.

BACCHARIS, in botany, *ploughman's spikenard*, a genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ discoides. The characters are; it has a naked receptacle, and hairy pappus; with a cylindrical imbricated calyx, and feminine florets mixed with the hermaphrodite ones. There are 9 species, all natives of warm climates; of which the two following chiefly merit notice.

1. Baccharis halimifolia, or Virginia groundsel tree, a native of Virginia and other parts of North America. It grows about 7 or 8 feet high, with a crooked shrubby stem; and flowers in October. The flowers are white, and not very beautiful; but the leaves continuing green, has occasioned this shrub to be admitted into many curious gardens. It may be propagated by cuttings; and will live very well in the open air, though severe frost will sometimes destroy it.

2. Baccharis ivæfolia, or African tree groundsel, a native of the Cape of Good Hope, as well as of Peru and other warm parts of America. It grows to the height of 5 or 6 feet; and though there is little beauty in the flower, has been long admitted into the gardens of the curious. It is pretty hardy, and will live abroad in moderate winters in England; but is usually kept in green houses, and placed abroad only in summer. It may be propagated either by cuttings or by seeds, which ripen well in this country.

BACCHIUS, in ancient poetry, a kind of foot composed of a short syllable and two long ones.

BACILLARIA, in natural history, a genus of vermes infusoriæ, of which only a single species is described. The body consists of straw like cylinders, placed parallel to each other, and frequently changes its direction and arrangement.

BACK, in brewing, a large flat kind of tub or vessel, in which the wort is put for cooling. The ingredients of beer pass through three kinds of vessels: they are mashed in one, worked in another, and cooled in a third. See Brewing.

Back *the sails*, is to put them in a situation that will occasion the ship to retreat or move astern.

Back, in the manege. To back a horse, or mount a horse *à dos* in French, is to mount him bare backed, or without a saddle.

BACK GAMMON, an ingenious game played with dice and tables, to be learned only by observation and practice. However, the following rules concerning it cannot fail to be acceptable to our readers. In the first place, the men, which are thirty in number, being equally divided between the two gamesters, are placed thus, *viz.* two on the ace point, five on the side of your left hand table, three on the cinque, and five on the ace point of your right hand table, which are answered on the like points by your adversary's men: or they may be disposed thus, *viz.* two on the ace point, five on the double sice or sice cinque point, three on the cinque point in your own tables, and five on the sice point at home; which are to be answered by your adversary. The men being thus disposed, be sure to make good your trey and ace points; hit boldly, and come away as fast as you can. When you come to bearing, have a care of making when you need not; and doublets now will stand you most in stead. If both bear together, he that is first off, without doublets, wins one; if both bear, and one goes off with doublets, he wins two. If your table be clear before your adversary's men are come in, that is a back gammon, which is three; but if you thus go off with doublets, it is four.

The great dexterity of this game is to be forward, if possible, upon safe terms; and so to point the men, that it shall not be possible for the adversary to pass, though you have entered your men, till you give him liberty, after having got two to one of the advantage of the game.

BACK STAFF, in the sea language, an instrument to take the sun's altitude. It consists of two concentric arches, the greater of which is divided into 30 degrees, and every degree into 5 minutes, by means of diagonal lines; and the lesser into 60 degrees. There are likewise 3 vanes belonging to it: that upon the arch of 30 degrees being called the sight vane; that upon the arch of 60 degrees, the shade vane; and the other in the centre of the arches, the horizon vein.

To find the sun's altitude by this instrument, fix the shade vane on the 60 degrees arch, at about 15 or 20 degrees less than the complement of the altitude; and turning your back toward the sun, move the sight vane up and down till the sun's image fall on the horizon vane, and at the same instant you see the horizon through the slit in the horizon vane; then will the degrees cut by the shade vane on the arch, being added to those cut by the sight vane on the other arch, be the sun's zenith distance at that time, which being subtracted from 90 degrees, will give his altitude.

BACOPA, in botany, a genus of the pentandria monogynia class and order: the essential character is, calyx with a short tube, spreading at top; stam. inserted into the tube of the corolla, stigma headed, caps. one celled.

There is but one species, an aquatic plant of Cayenne, celebrated by the inhabitants for its efficacy in curing burns.

BACTRIS, in botany, a genus of the class and order monoecia hexandria. In the male flowers the calyx is 3 parted; corolla 1 petalled, 3 cleft; stam. 6; fem. cal. 1 leafed, 3 toothed; cor. the same, stigma 3 cleft, drupe coriaceous. This genus is classed among the palms: there are two species, the majus and minus, both natives of Carthagena, where the fruit is eaten.

BACULARES, a sect of anabaptists, so called as holding it unlawful to bear a sword, or any other weapon besides a staff.

BACULE, in fortification, a kind of portcullis, or gate, made like a pitfall with a counterpoise, and supported by two great stakes. It is usually made before the corps de garde, not far from the gate of a place.

BADGER, in zoology. See URSUS.

BADGER, in old law books, one that was licensed to buy corn in one place, and carry it to another to sell, without incurring the punishment of an engrosser. They are to be annually licensed by the justices.

BADIAGA, a water plant resembling a sponge, and said to be good for removing the livid marks from blows.

BADIANE, or BADIAN, the seed of a tree which grows in China, and smells like annise seed. The Chinese, and the Dutch, in imitation of them, sometimes use the badiane to give their tea an aromatic taste.

BADIGEON, a mixture of plaster and freestone, used by statuaries to fill up little holes.

BÆCKEA, in botany, a genus of the octandria order and monogynia class of plants. The calyx is a permanent perianthium, consisting of a single funnel shaped leaf, cut into 5 segments at the brim; the corolla consists of 5 roundish petals inserted into the calyx; the pericarpium is a globose capsule, made up of 4 valves, and containing 4 cells, in which are a few roundish angular seeds. There is one species, a native of China.

BÆOBOTRYS, a genus of the pentandria monogynia class and order. The essential character is, cor. tubular; border 5 cleft; cal. double, outer 2 leaved, inner 1 leafed, bell shaped; berry globose, 1 celled, growing to calyx, many seeded. There is but one species, a native of Zanna in the South Seas.

BÆTYLIA, anointed stones, worshipped by the Phenicians, and by other barbarous nations.

BAFFETAS, or BASTAS, a cloth made of coarse white cotton thread, which comes from the East Indies. Those of Surat are the best.

BAG, among farriers, is when, in order to retrieve a horse's lost appetite, they put an ounce of asafœtida, and as much powder of savin, into a bag, to be tied to the bit, keeping him bridled for two hours, several times a day: as soon as the bag is taken off, he will fall to eating. The same bag will serve a long time.

BAGNOLIANS, BAGNOLENSES, in church history, a sect of heretics, who in reality were manichees, though they somewhat disguised their errors. They rejected the Old Testament, and part of the New; held the world to be eternal, and affirmed that God did not create the soul when he infused it into the body.

BAGPIPE, a musical instrument of the wind kind, chiefly used in country places, especially in the north; it consists of two principal parts; the first a leathern bag, which blows up like a football, by means of a port vent, or little tube, fitted to it, and stopped by a valve; the other part consists of three pipes or flutes, the first called the great pipe, or drone, and the second the little one; which pass the wind out only at the bottom: the third has a reed, and is played on by compressing the bag under the arm, when full, and opening and stopping the holes, which are eight, with the fingers. The little pipe is ordinarily a foot long; that played on, thirteen inches; and the port vent six.

BAGUETTE, in architecture, a small round moulding, less than an astragal, and so called from the resemblance it bears to a ring.

BAHAR, or BARRE, in commerce, weights used in several places in the East Indies.

There are two of these weights, the one the great bahar, with which they weigh pepper, cloves, nutmegs, ginger, &c. and contains about 5cwt. and 24 pounds 9 ounces, avoirdupois weight. With the little bahar they weigh quicksilver, vermilion, ivory, silk, &c. It contains about 437 pounds 9 onnces.

BAIL, in law, the setting at liberty one arrested, or imprisoned, upon an action either civil or criminal, upon sureties taken for his appearance at a day and place assigned. In civil cases the bail is either common or special. Common bail is a matter of course, being nothing but a mere form upon appearance, after personal service of the writ, and notice to appear upon the defendant. If he appear thereto, his attorney puts in imaginary sureties for his future attendance, as John Doe and Richard Roe. But if the plaintiff will make affidavit that the cause of action amounts to 10*l.* or upward, in order to arrest the defendant, and make him put in substantial sureties for his appearance, called special bail; it is then required that the true cause of action be expressed in the body of the writ, or process. 3 Blacks. 287.

Special bail, are two or more persons, who, after the arrest, undertake generally, or enter into bond to the sheriff in a certain sum, to ensure the defendant's appearance at the return of the writ; this obligation is called the bail bond.

Bail in criminal cases. Upon offering sufficient surety, bail may be taken either in court, or in some particular cases, by the sheriff, coroner, or other magistrate, but most usually by justices of the peace, in the following cases: Persons of good fame charged with a bare suspicion of manslaughter, or other inferior homicide. Persons charged with petit larceny, or any felony not before specified. Accessories to felony, not being of evil fame, nor under strong presumption of guilt. But bail cannot be taken upon an accusation of treason, nor of murder, nor in the case of manslaughter if the person is clearly the slayer; nor such as being committed for felony have broken prison, nor persons outlawed, nor such as have abjured the realm, nor approvers, nor persons taken with the maner, or in the fact of felony, nor persons charged with housebnrning, nor persons taken by writ of excommunicato capiendo.

BAILE, or BALE, in the sea language. The seamen call throwing the water by hand out of the ship or boat's hold, bailing. They also call those hoops that bear up the tilt of a boat, its bails.

BAILMENT, in law, is a delivery of things, whether writings, goods, &c. to another, sometimes to be delivered back to the bailer; that is, to him who so delivered them; sometimes to the use of the bailee; that is, of him to whom they are delivered; and sometimes also to be delivered to a third person; this delivery is called a bailment. 2 Blacks. 451.

The following rules are laid down as actions in the law of bailments: A bailee, who derives no benefit from his undertaking, is responsible only for gross negligence. A bailer, who alone receives benefit from the bailment, is responsible for slight neglect. When the bailment is beneficial to both parties, the bailee must answer for ordinary neglect. A special agreement of the bailee to answer for more or less, is in general valid. All bailers are answerable for actual fraud, even though the contrary be stipulated. No bailee shall be charged for a loss by inevitable accident, or irresistible force, except by special agreement. Robbery by force is considered as irresistible; but a loss by private stealth, is presumptive evidence of ordinary neglect. Gross neglect is a violation of good faith. No action lies to compel performance by a naked contract. The negligence of a servant acting by his master's orders, expressed or implied, is the negligence of the master.

BAILIFF, a keeper, or protector. Hence the sheriff is considered as bailiff to the crown: and the county of which he has the care, and in which he is to execute the king's writ, is called his bailiwick; so also his officers who execute writs, warrants, &c. are called bailiffs.

BAILIFF, *water*, an officer appointed in all port towns, for the searching of ships, gathering the toll for anchorage, &c. and arresting persons for debts, &c. on the water.

BAILIFF is still applied to the chief magistrate of several corporate towns. The government of some of the king's castles is also committed to persons called bailiffs, as the bailiff of Dover castle.

In France, bailiffs have some considerable prerogatives; they are reputed heads of their respective districts, or administer justice by their lieutenants, at least within the precincts of the several parliaments or provinces of France. In their name justice is administered, contracts and other deeds passed, and to them is committed the command of the militia.

In Scotland, bailiff is the name of a judge, as well as the appellation of alderman.

BAILIFFS *of courts baron*, summon those courts, and execute the process thereof; they present all pound breaches, cattle strayed, &c.

BAILIWICK, signifies sometimes that liberty which is exempted from the sheriff of the county, over which the lord of the liberty appoints a bailiff, such as the bailiff of Westminster.

BAILS, *clerk of the*, is an officer belonging to the court of king's bench: he files the bail pieces taken in that court, and attends for that purpose.

BAIOCAO, a copper coin, current at Rome, and throughout the whole state of the church, ten of which make a julio, and an hundred a Roman crown.

BAIRAM, in the Mahometan customs, a yearly festival of the Turks, which they keep after the fast of ramazan.

The Mahometans have two bairams, the great and the little. The little bairam continues for three days, and is seventy days after the first, which follows immediately after the ramazan. During the bairam the people leave their work for three days, make presents to one another, and spend the time with great manifestations of joy. If the day after ramazan should prove so cloudy as to prevent the sight of the new moon, the bairam is put off to the next day, when it is kept, even if the moon should still be obscured. When they celebrate this feast, after numerous ceremonies, or rather strange mimicries, in their mosque, it is concluded with a solemn prayer against the infidels, to extirpate Christian princes, or to arm them against one another, that they may have an opportunity to extend the limits of their law.

BAITING is applied to the act of smaller or weaker beasts attacking and harassing greater and stronger ones. Bulls and bears are baited by mastiffs, or bull dogs. The practice of bull baiting, and other sports of the same kind, which cannot be too strongly reprobated, may be traced to an early period of our history. In the twelfth century, it was a common practice on every holiday. In the reign of Henry VIII. many herds of bears were maintained for the purpose of baiting. Queen Mary had a great exhibition of bear baiting immediately after mass, with which to entertain her sister Elizabeth, then a prisoner in Hatfield house; and the same princess, soon after her accession to the throne, entertained the foreign ambassadors with the baiting of bulls and bears. The custom of bull baiting was most ingeniously defended by Mr. Windham in the house of commons in the session of 1803, when a bill was brought in to stop that inhuman practice. Whales are baited by a kind of fish called oriæ, or killers, ten or twelve of which will attack a young whale at once, and not leave him till he is killed. Philos. Trans. No. 287.

BAJULUS, an ancient officer in the court of the Greek emperors.

BAKER, a person whose occupation or business is to prepare bread, or to reduce meals of any kind, whether simple or compound, into bread, biscuits, &c.

It is not known when this very useful business first became a particular profession. Bakers were a distinct body of people in Rome nearly two hundred years before the Christian era, and it is supposed that they came from Greece. To these were added a number of freemen, who were incorporated into a *college*, from which neither they nor their children were allowed to withdraw. They held their effects in common without enjoying any power of parting with them. Each bakehouse had a *patron*, who had the superintendency of it; and one of the patrons had the management of the others, and the care of the college. So respectable were the bakers at Rome, that occasionally one of the body was admitted among the senators.

Even by our own statutes the bakers are declared not to be handicrafts; and in London they are under the particular jurisdiction of the lord mayor and aldermen, who fix the price of bread, and have the power of fining those who do not conform to their rules.

Bread is made of flour mixed and kneaded with yeast, water, and a little salt. It is known in London under two names, the *white* or *wheaten*, and the *household:* these differ only in degrees of purity: and the loaves must be marked with a W or H, or the baker is liable to suffer a penalty.

The process of bread making is thus described: To a peck of meal are added a handful of salt, a pint of yeast, and three quarts of water, cold in summer, hot in winter, and temperate between the two. The whole being kneaded, will rise in about an hour; it is then moulded into loaves, and put into the oven to bake. The oven takes more than an hour to heat properly, and bread about three hours to bake.

The price of bread is regulated according to the price of wheat; and bakers are directed in this by the magistrates, whose rules they are bound to follow. By these the peck loaf of each sort of bread must weigh seventeen pounds six ounces avoirdupois weight, and smaller loaves in the same proportion. Every sack of flour is to weigh two hundred and a half; and from this there ought to be made, at an average, twenty such peck loaves, or eighty common quartern loaves.

If the bread was short in its weight only one ounce in thirty-six, the baker formerly was liable to be put in the pillory; and for the same offence he may now be fined, at the will of the magistrate, in any sum not less than one shilling, nor more than five shillings for every ounce wanting; such bread being complained of and weighed in the presence of the magistrate within twenty-four hours after it is baked, because bread loses in weight by keeping.

It is said that scarcely any nation lives without bread, or something as a substitute for it. The Laplanders have no corn, but they make bread of their dried fishes, and of the inner rind of the pine, which seems to be used not so much on account of the nourishment to be obtained from it, as for the sake of having a dry food. In Norway they make bread that will keep thirty or forty years, and the inhabitants esteem the old and stale bread in preference to that which is newly made. For their great feasts particular care is taken to have the oldest bread; so that at the christening of a child, for instance, they have usually bread which has been baked perhaps at the birth of the father, or even grandfather. It is made from barley and oats, and baked between two hollow stones.

The process of biscuit baking, as practised at the victualling office at Deptford, is curious and interesting. The dough, which consists of flour and water only, is worked by a large machine. It is then handed over to a second workman, who slices it with a large knife for the bakers, of whom there are five. The first, or the *moulder*, forms the biscuits two at a time; the second, or *marker*, stamps and throws them to the *splitter*, who separates the two pieces, and puts them under the hand of the *chucker*, the man that supplies the oven, whose work of throwing the bread on the peel must be so exact, that he cannot look off for a moment. The fifth, or the *depositor*, receives the biscuits on the peel, and arranges them in the oven. All the men work with the greatest exactness, and are, in truth, like parts of the same machine. The business is to deposite in the oven seventy biscuits in a minute; and this is accomplished with the regularity of a clock, the clacking of the peel operating like the motion of the pendulum. There are twelve ovens at Deptford, and each will furnish daily bread for 2040 men.

The bakers of London make a distinct company, the nineteenth in order.

BALÆNA, the whale, in zoology, a genus of the mammalia class, belonging to the order of ceti. The characters of this genus are these: the balæna, in place of teeth, has a horny plate on the upper jaw, and a double fistula or pipe for throwing out water. There are four species: *viz.*

1. Balenæa bo-ops, the pike headed whale, has a double pipe in its snout, three fins, and a hard horny ridge on its back. The belly is full of longitudinal folds or rugæ. It frequents the northern ocean. The length of one taken on the coast of Scotland, as remarked by sir Robert Sibbald, was forty-six feet, and its greatest circumference twenty. This species takes its name from the shape of its nose, which is narrower and sharper pointed than that of other whales.

2. Balæna musculus has a double pipe in its front, and three fins; the under jaw is much wider than the upper one. It frequents the Scotch coasts, and feeds upon herrings.

3. Balæna mysticetus, the common or great Greenland whale, which has no fin on the back. This is the largest of all animals; it is even at present sometimes found in the northern seas ninety feet in length; but formerly they were taken of a much greater size, when the captures were less frequent, and the fish had time to grow. Such is their bulk within the arctic circle: but in the torrid zone, where they are less molested, whales are still seen one hundred and sixty feet long. The head is very much disproportioned to the size of the body, being one third of the size of the fish: the under lip is much broader than the upper. The tongue is composed of a very soft spongy fat, capable of yielding five or six barrels of oil. The gullet is very small for so vast a fish, not exceeding four inches in width. In the middle of the head are two orifices, through which it spouts water to a vast height, and with a great noise, especially when disturbed or wounded; the eyes are placed toward the back of the head, being the most convenient situation for enabling them to see both before and behind; as also to see over them, where their food is principally found. They are guarded by eyelids and eyelashes, as in quadrupeds; and the animals seem to be very sharp sighted. Nor is their sense of hearing in less perfection; for they are warned at a great distance of any danger preparing against them. It is true, indeed, that the external organ of hearing is not perceptible, for this might only embarrass them in their natural element; but as soon as the thin scarf skin after mentioned is removed, a black spot is discovered behind the eye, and under that is the auditory canal, that leads to a regular apparatus for hearing. In short, the animal hears the smallest sounds at very great distances, and at all times, except when it is spouting water; which is the time that the fishers approach to strike it. What is called whalebone, adheres to the upper jaw, and is formed of thin parallel laminæ, some of the longest four yards in length; of these there are commonly 350 on each side, but in very old fish more. They are surrounded with long strong hair, not only that they may not hurt the tongue, but as strainers to prevent the return of their food, when they discharge the water out of their mouth. The real bones of the whale are hard, porous, and full of marrow. Two very strong bones sustain the upper lip, lying against each other in the shape of a half moon. The tail is broad and semilunar; and when the fish lies on one side, its blow is tremendous. The tail alone it makes use of, to advance itself forward in the water; and it is surprising with what force and celerity its enormous bulk cuts through the ocean. The fins are only made use of for turning in the water, and giving a direction to the velocity impressed by the tail. The female also makes use of them, when pursued, to bear off her young, clapping them on her back, and supporting them by the fins on each side from falling. The whale varies in colour; the back of some being red, the belly generally white. Others are black, some mottled, and others quite white. Their colours in the water are extremely beautiful, and their skin is very smooth and slippery. The outward or scarf skin of the whale is no thicker than parchment; but this removed, the real skin appears, of about an inch thick, and covering the fat or blubber that lies beneath: this is from eight to twelve inches in thickness; and is, when the fish is in health, of a beautiful yellow. The muscles lie beneath; and these, like the flesh of quadrupeds, are very red and tough. The teats in the female are placed in the lower part of the belly. They breed only once in two years. Their fidelity to each other exceeds whatever we are told even of the constancy of birds. Some fishers, as Anderson informs us, having struck one of two whales, a male and a female, that were in company together, the wounded fish made a long and terrible resistance; it struck down a boat with three men in it, with a single blow of its tail, by which all went to the bottom. The other still attended its companion, and lent it every assistance; till, at last, the fish that was struck sunk under the number of its wounds; while its faithful associate, disdaining to survive the loss, with great bellowing, stretched itself upon the dead fish, and shared its fate. The whale goes with young nine or ten months, and is then fatter than usual, particularly when near the time of bringing forth. It is said that the embryo, when first perceptible, is about seventeen inches long, and white; but the cub, when excluded, is black, and about ten feet long. She generally produces one young one, and never above two. When she suckles her young, she throws herself on one side of the surface of the sea, and the young one attaches itself to the teat. Nothing can exceed the tenderness of the female for her offspring. Even when wounded, she still clasps her young one; and when she plunges to avoid danger, takes it to the bottom; but rises sooner than usual, to give it breath again. The young ones continue at the breast for a year; during which time, they are called by the sailors, *short heads*. They are then extremely fat, and yield above fifty barrels of blubber. The mother at the same time is equally lean and emaciated. At the age of two years they are called *stunts*, as they do not thrive much immediately after quitting the breast; they then yield scarcely above twenty or twenty-four barrels of blubber: from that time forward they are called *skull fish*, and their age is wholly unknown. The food of the great whale is a small sea insect well known under the name of the Medusa or sea blubber.

4. Balæna physalus, or fin fish, see Plate XV. Nat. Hist. fig. 44. is distinguished from the common whale by a fin on the back, placed very low and near the tail. The length is equal to that of the common kind, but much more slender. It is furnished with whalebone in the upper jaw, mixed with hairs, but short and knotty, and of little value. The blubber also in the body of this kind is very inconsiderable. These circumstances, added to its extreme fierceness and agility, which render the capture very dangerous, cause the fishers to neglect it. The natives of Greenland, however, hold it in great esteem, as it affords a quantity of flesh which to their palate is very agreeable. The lips are brown, and like a twisted rope: the spout hole is seemingly split in the top of its head, through which it blows water with much more violence, and to a greater height, than the common whale. The fishers are not very fond of seeing it, for on its appearance the others retire out of those seas. It feeds on herrings and small fish. Inoffensive as the whale is, it is not without enemies. There is a small animal, of the shell fish

kind called the whale louse, that sticks to its body, as we see shells sticking to the foul bottom of a ship. This insinuates itself chiefly under the fins; and whatever efforts the great animal makes, it still keeps its hold, and lives upon the fat, which it is provided with instruments to arrive at.

The swordfish, however, is the whale's most terrible enemy. "At the sight of this little animal," says Anderson, "the whale seems agitated in an extraordinary manner, leaping from the water as if with affright: wherever it appears, the whale perceives it at a distance, and flies from it in the opposite direction. I have been myself," continues he, "a spectator of their terrible encounter. The whale has no instrument of defence except the tail; with that it endeavours to strike the enemy; and a single blow taking place would effectually destroy its adversary: but the swordfish is as active as the other is strong, and easily avoids the stroke; then bounding into the air, it falls upon its enemy, and endeavours not to pierce with its pointed beak, but to cut with its toothed edges. The sea all about is soon dyed with blood, proceeding from the wounds of the whale; while the enormous animal vainly endeavours to reach its invader, and strikes with its tail against the surface of the water, making a report at each blow, louder than the noise of a cannon."

There is still another powerful enemy to this fish, which is called the orien or killer. A number of these are said to surround the whale in the same manner as dogs get round a bull. Some attack it with their teeth behind; others attempt it before: until, at last, the great animal is torn down, and its tongue is said to be the only part they devour when they have made it their prey.

But of all the enemies of these enormous fishes man is the greatest: he alone destroys more in a year than the rest in an age; and actually has thinned their numbers in that part of the world where they are chiefly sought. At the first discovery of Greenland, whales not being used to be disturbed frequently, came into the very bays, and were accordingly killed almost close to the shore; so that the blubber being cut off, was immediately boiled into oil on the spot. The ships, in those times, took in nothing but the pure oil and the whalebone, and all the business was executed in the country; by which means a ship could bring home the product of many more whales than she can according to the present method of conducting this trade. The fishery also was then so plentiful, that they were obliged sometimes to send other ships to fetch off the oil they had made, the quantity being more than the fishing ships could bring away. But time and change of circumstances have shifted the situation of this trade. The ships coming in such numbers from Holland, Denmark, Hamburgh, and other northern countries, all intruders upon the English, who were the first discoverers of Greenland, the whales were disturbed; and gradually, as other fish often do, forsaking the place, were not to be killed so near the shore as before; but are now found, and have been so ever since, in the openings and space among the ice, where they have deep water, and where they go sometimes a great many leagues from the shore.

The whale fishery begins in May, and continues all June and July; but whether the ships have good or bad success, they must come away, and get clear of the ice, by the end of August; so that in the month of September at furthest they may be expected home; but a ship that meets with a fortunate and early fishery in May, may return in June or July.

The manner of taking whales at present is as follows: Every ship is provided with six boats, to each of which belong six men for rowing the boat, and an harpooner, whose business is to strike the whale with his harpoon. Two of these boats are kept constantly on the watch at some distance from the ship, fastened to pieces of ice, and are relieved by others every four hours. As soon as a whale is perceived, both the boats set out in pursuit of it, and if either of them can come up before the whale finally descends, which is known by his throwing up his tail, the harpooner discharges his harpoon at him. There is no difficulty in choosing the place where the whale is to be struck, as some have asserted; for these creatures only come up to the surface in order to spout up the water, or *blow*, as the fishermen term it, and therefore always keep the soft and vulnerable part of their bodies above water. A late improvement was made in the method of discharging the harpoon, namely, by shooting it out of a kind of swivel or musketoon: but it does not appear that since this improvement was made, the whale fishing ships have had better success than before. As soon as the whale is struck, the men set up one of their oars in the middle of the boat as a signal to those in the ship. On perceiving this, the watchman alarms all the rest with the cry of *fall! fall!* upon which all the other boats are immediately sent out to the assistance of the first.

The whale, finding himself wounded, runs off with prodigious violence. Sometimes he descends perpendicularly; at others, goes off horizontally, at a small depth below the surface. The rope which is fastened to the harpoon is about two hundred fathoms long, and properly coiled up, that it may freely be given out as there is a demand for it. At first the velocity with which this line runs over the side of the boat is so great, that it is wetted to prevent its taking fire: but in a short time the strength of the whale begins to fail, and the fishermen, instead of letting out more rope, strive as much as possible to pull back what is given out already, though they always find themselves necessitated to yield at last to the efforts of the animal, to prevent his sinking their boat. If he runs out the two hundred fathoms of line contained in one boat, that belonging to another is immediately fastened to the end of the first, and so on; and there have been instances, where all the rope belonging to the six boats has been necessary, though half that quantity is seldom required. The whale cannot stay long below the water, but again comes up to blow: and being now much fatigued and wounded, stays longer above water than usual. This gives another boat time to come up with him, and he is again struck with another harpoon. He again descends, but with less force than before; and when he comes up again, is generally incapable of descending, but suffers himself to be wounded and killed with long lances, which the men are provided with for the purpose. He is known to be near death when he spouts up the water deeply tinged with blood.

The whale being dead, is lashed alongside the ship. They then lay it on one side, and put two ropes, one at the head, and the other in the place of the tail, which together with the fins, is struck off as soon as he is taken, to

keep these extremities above water. On the off side of the whale are two boats, to receive the pieces of fat, utensils, and men, that might otherwise fall into the water on that side. These precautions having been taken, three or four men with irons at their feet, to prevent slipping, get on the whale, and begin to cut out pieces of about three feet thick and eight long, which are hauled up at the capstan or windlass. When the fat is all got off, they cut off the whiskers of the upper jaw with an axe. Before they cut, they are all lashed to keep them firm: which also facilitates the cutting, and prevents them from falling into the sea. When on board, five or six of them are bundled together, and properly stowed; and after all is got off, the carcass is turned adrift, and devoured by the bears, who are very fond of it. In proportion as the large pieces of fat are cut off, the rest of the crew are employed in slicing them smaller, and also in picking out all the lean. When this is prepared, they stow it under the deck, where it lies till the fat of all the whales is on board; then cutting it still smaller, they put it up in casks in the hold, cramming them very full and close. Nothing now remains but to sail homeward, where the fat is boiled, and melted down into train oil.

BALANCE, or *ballance*, in mechanics, one of the simple powers which serve to find out the equality or difference of weight in heavy bodies. See MECHANICS.

The modern balance consists of a lever, suspended exactly by the middle, and scales affixed to each extremity: the principle on which each is founded is the same, and may be easily conceived.

BALANCE, *hydrostatical*. See the article HYDROSTATICS.

BALANCE *of trade*, in commerce, the equality between the value of the commodities bought of foreigners, and the value of the native productions transported into other nations.

It is reckoned that that nation has the advantage in the balance of trade, which exports more of native commodities, and imports less of the foreign; so that the nation grows so much richer in bullion as the balance of that trade amounts to, which must be made up of bullion or money.

Among various others, the most received methods of arriving at the knowledge whether a nation gains or loses by foreign trade, or any branch thereof, are the following:

1°. A strict survey must be taken of what proportion the value of the commodities exported bears to those imported. If the exports exceed the imports, it is concluded that that nation is so far in a gaining way, by the overplus imported in bullion. But this method is uncertain, from the difficulty of obtaining a true account, either of the exports or imports; as custom house books are no rule in this case, on account of the running of goods, especially many fine commodities of small bulk, but great value; besides the various accidents which affect the value of the stock, either sent out or brought in, as losses at sea, &c.

2°. The second method, no less defective than the other, is by observing the course of exchange, which if generally above the intrinsic value, or par of the coins of foreign countries, we not only lose by such exchange, but the same is a proof that we lose by the general course of our trade.

3°. The third method is made from the increase or the diminution of our trade and shipping in general; for if these diminish, the nation loses, and *vice versa:* this seems equally imperfect with the following.

4°. A fourth way is, by observing the increase and diminution of our coin and bullion.

BALANCE of a clock or watch. See the article CLOCKWORK.

BALANCE *fish*. See ZYGÆNA.

BALANI *marini*, certain multivalve shells, usually growing in clusters on the shells of the larger sort of sea shell fish. See LEPAS.

BALCONY, in architecture, a projection in the front of a house, or other building, supported by pillars or consoles, and encompassed with a balustrade: or it is a kind of open gallery for people to stand in, to behold any public show, or for taking the air in.

BALCONY, in a ship, is a gallery either covered or open, made abaft, either for ornament or convenience of the captain's cabin.

BALDACHIN, or BALDAQUIN, in architecture, a building in form of a canopy, supported by pillars, and frequently used as a covering to insulated altars. Some also use the term baldachin for the shell over a door.

BALE, in commerce, is said of merchandises packed up in cloth, and corded round very tight, in order to keep them from breaking, or preserve them from the weather.

A bale of cotton yarn is from three to four hundred weight; of raw silk, it is from one to four hundred; of lockram or dowlass either three, three and a half, or four pieces.

BALE *goods*, among the English merchants, are all such as are imported or exported in bales; but the French give that name to certain hard wares, and other sort of merchandise, which come to Paris, and are commonly made by bad workmen, of indifferent materials.

BALISTES, in ichthyology, a genus of fishes belonging to the order of amphibia nantes. The characters are these: the head is flat; there are eight teeth in each side, and the two anterior ones are longest; in the place of gills, the balistes has an aperture immediately above the pectoral fins; the body is flat, the scales are joined together by the skin, and the belly is keeled. There are 24 species of this genus: the most remarkable are,

1. Balistes aculeatus, which has a triradiated back fin; and the spines of the tail lean upon each other. It is a native of India.

2. Balistes hispidus has the head fin uniradiated; and there is a round black spot in the tail fin. The body is rough, and bristly toward the tail. The spine or horn is situated between the eyes; the snout is subulated; and instead of a belly fin, it has a ragged sharp spine. This species is a native of Carolina.

3. Balistes monoceros, whose head fin consists of but one ray, and the tail rays are carinated. It is called the *unicorn fish* by Catesby, who informs us that the intestines of this fish are full of small shells and coralline substances, which by the strength and hardness of its jaw it is enabled to grind very small. These fish, he adds, are not eaten, being accounted poisonous. They most frequent those seas, amongst the Bahama islands, where the corals are in greatest plenty.

4. Balistes papillosus has a biradiated back fin, and a papillous body.

5. Balistes ringens has a triradiated back fin; there are three folds in each side of the head, and the tail fin is forked. It is found at Ascension Island.

6. Balistes tomentosus, whose head fin is biradiated, and the body of it toward the hind part is hairy. It is a native of America.

7. Balistes verrucosus has a triradiated back fin, and the tail is full of little warts. In the place of a belly fin, this species has a large, thick, warty ray. It has 25 small reversed sharp spines at the side of the tail, disposed in four rows. It is a native of India.

8. Balistes vetula, or old wife, has a triradiated back fin; the belly fin is longitudinal, and somewhat carinated; and the tail is fin forked. It is found at Ascension Island. See Plate XV. Nat. Hist. fig. 45.

Nearly all the fishes of this genus, which by Linnæus is divided into nineteen species, but by later writers into twenty-four, are remarkable for their splendid colours.

BALIVO *amovendo*, in law, was a writ for removing a bailiff from his office, for want of having sufficient land in his bailiwick to answer the king and his people, according to the statute of Westminster, 2 reg. Orig. 78.

BALLS *of fire*, in meteorology, are meteors seen passing over countries, and estimated to be at considerable heights in the atmosphere.

Ball, in the military art, comprehends all sorts of bullets for fire arms, from the cannon to the pistol.

Cannon balls are of iron; musket balls, pistol balls, &c. are of lead. The experiment has been tried of iron balls for pistols and fusees, but they are justly rejected, not only on account of their lightness, which prevents them from flying straight, but because they are apt to furrow the barrel of the pistol.

Cannon balls are distinguished by their calibres thus:

A 42	pound ball, the diameter of which is	6,684 inches
32		6,105
24		5,547
18		5,040
12		4,403
9		4,000
6		3,498
3		2,775
2		2,423
1		1,923

Balls, *fire*, } of which there are various sorts used
Balls, *light*, } for various purposes. Their composition is mealed powder two, saltpetre one and a half, sulphur one, resin one, turpentine two and a half. Sometimes they are made of an iron shell, sometimes of a stone, filled and covered with various coats of the above composition, till it conglomerates to a proper size; the last coat being of grained powder. But the best sort is to take thick brown paper, and make a shell the size of the mortar, and till it with a composition of an equal quantity of sulphur, pitch, resin, and mealed powder; which being well mixed, and put in warm, will give a clear fire, and burn a considerable time.

When they are intended to set fire to magazines, buildings, &c. the composition must be mealed powder ten, saltpetre two, sulphur four, and resin one; or rather mealed powder forty-eight, saltpetre thirty-two, sulphur sixteen, resin four, steel or iron filings two, fir tree sawdust boiled in saltpetre lye two, birch wood charcoal one, well rammed into a shell for that purpose, having various holes filled with small barrels, loaded with musket balls; and, lastly, the whole immerged in melted pitch, resin, and turpentine oil.

Balls, *smoke*, are prepared as above, with this difference, that they contain five to one of pitch, resin, and sawdust. This composition is put into shells made for that purpose, having four holes to let out the smoke. Smoke balls are thrown out of mortars, and continue to smoke from twenty-five to thirty minutes.

Balls, *stink*, are prepared by a composition of mealed powder, resin, saltpetre, pitch, sulphur, rasped horses' and asses' hoofs burnt in the fire, asafœtida, seraphim gum or ferula, and bug or stinking herbs, made up into balls, as mentioned of *light balls*, agreeably to the size of the mortar out of which you intend to throw them.

Balls, *poisoned*. We are not sure that they have ever been used in Europe; but the Indians and Africans have always been very ingenious at poisoning several sorts of warlike stores and instruments. Their composition is mealed powder 4, pitch 6, resin 3, sulphur 5, asafœtida 8, poisonous substances, chiefly euphorbia, 12, made into balls as above directed. At the commencement of the French revolution, poisoned balls were exhibited to the people, as pretended to have been fired by the Austrians, particularly at the seige of Lisle. They contained glass, small pieces of iron, &c. and were said to be concocted together by means of a greasy composition which was impregnated with poisonous matter. In 1792 they were deposited in the archives of Paris.

Balls, *red hot*, are fired out of mortars, howitzers, or cannon. Use which you will, the ball must be made red hot, which is done upon a large coal fire in a square hole made in the ground, six feet every way, and four or five feet deep. Some make the fire under an iron grate, on which the shell or ball is laid; but the best way is to put the ball into the middle of a clear burning fire, and when red hot, all the fiery particles must be swept off. Whatever machine you use to throw the red hot ball out of, it must be elevated according to the distance you intend it shall range, and the charge of powder must be put into a flannel cartridge, and a good wadding upon that; then a piece of wood of the exact diameter of the piece, and about three and a half inches thick, to prevent the ball from setting fire to the powder; then place the ball on the edge of the mortar, &c. with an instrument for that purpose, and let it roll of itself against the wood, and instantly fire it off. Should there be a ditch or parallel before such a battery, with soldiers, the wood must not be used, as the blast of powder will break it to pieces, and its own elasticity prevent it from flying far; it would in that case either kill or wound your own people: for this deficiency the wadding must be double.

Balls, *chain*, are two balls linked together by a chain of eight or ten inches long, and some have been made with a chain of three or four feet long; they are used to destroy the palisadoes, wooden bridges, &c. of a fortification; they are also very destructive to the rigging of a ship.

Ball *and socket* is an instrument made of brass, with a perpetual screw, so as to move horizontally, vertically, and obliquely; and is generally used for the managing of surveying instruments, and astronomical instruments.

BALL, *puff*, the English name of the lycoperdon. See LYCOPERDON.

BALLAD generally means a kind of song, adapted to the capacity of the lower class of people. It has not, however, been always confined to low and inferior compositions. In an old English version of the Bible, Solomon's Song is designated as the *ballad of ballads*. Some have supposed that the knowledge of the ballads in common use is necessary to a minister of state to learn the temper and disposition of the people; and lord Cecil, prime minister to queen Elizabeth, is said to have made an ample collection of ballads for this purpose. See Dr. Percy's Collection of old English and Scottish Ballads, and a dissertation prefixed to Dr. Aikin's Collection of Songs.

BALLAST, a quantity of stones, gravel, or sand, laid in a ship's hold, to make her sink to a certain depth into the water, and sail upright, rendering her of a prodigious weight. The ballast is sometimes one quarter, one third, or one half, of the ship's burden, according to the difference of the bulk. Flat vessels require the most ballast.

The following table will exhibit in one view the quantity of ballast allowed to ships of different sizes:

Ballast allowed to the following Ships.

Guns.	Tonnage.	Iron Tons.	Shingle Tons.
110	2290	180	370
100	2090	180	370
98	2110	160	350
90	1870	160	350
80	1620	140	300
74	1700	80	270
64	1370	70	260
50	1100	65	170
44	900	65	160
38	930	70	170
36	870	65	160
32	700	65	140
28	600	60	100
24	500	50	80
22	450	50	70
20	400	50	60
Sloop	300	50	40
Brig	160	30	15
Cutter	——	20	Seldom
Sloop	——	15	any.

The iron ballast is first stored fore and aft, from bulk head to bulk head; then the shingle ballast is spread and levelled over the iron.

Ships are said to be in ballast when they have no other loading. Masters of vessels are obliged to declare the quantity of ballast they bear, and to unload it at certain places. They are prohibited unloading their ballast in havens, roads, &c. inattention to which has ruined many excellent ports.

BALLET, a kind of dramatic poem, representing some fabulous action or subject divided into several acts, in which several persons appear, and recite things under the name of some deity, or other illustrious character. The term is now particularly used for a stage dance.

BALLET is likewise the name given, in France, to a whimsical kind of opera, in which dancing is a principal part of the performance. In most of these ballets the several acts seem so many different subjects, connected only by some general relation foreign to the action, which the spectator could not discover, if it was not made known in the prologue.

BALLIAGE, a small duty paid to the city of London by aliens and others for certain commodities exported by them, which they claim by their charter.

BALLISTA, in antiquity, a military machine used by the ancients in besieging cities, to throw large stones, darts, and javelins.

It resembled our crossbows, though much larger and superior in force.

From this engine, stones of a size not less than mill stones were thrown with so great violence as to dash whole houses in pieces at a blow. It is described thus: a round iron cylinder was fastened between two planks, from which reached a hollow square beam, placed crosswise, and fastened with cords, to which were added screws; at one end of this stood the engineer, who put a wooden shaft with a big head into the cavity of the beam: this done, two men bent the engine by drawing some wheels: when the top of the head was drawn to the utmost end of the cords, the shaft was driven out of the ballista, &c.

BALLOON, or *ballon*, in a general sense, signifies any spherical hollow body, of whatever matter it is composed, or for whatever purposes it is designed.

Thus, with chymists, balloon denotes a round short necked vessel, used to receive what it is distilled by means of fire; in architecture, a round globe on the top of a pillar; and among engineers, a kind of bomb made of pasteboard, and played off in fireworks, either in the air or in the water, in imitation of a real bomb.

Balloon, in the French paper trade, is a term for a quantity of paper, containing twenty four reams. It is also the name of a sort of brigantine used in the kingdom of Siam.

BALLOON, *air*. See AIR BALLOON.

BALLOTA, white horehound, a genus of the gymnospermia order and didynamia class of plants; and in the natural method ranking under the 42d order, verticillatæ. The calyx has five teeth, with ten striæ; and the upper lip of the corolla is crenated. It is a common weed growing on the sides of banks in most parts of England, so is seldom admitted into gardens. The flowers grow in whorls, upon branching peduncles, and lean on one side of the stalk; they are commonly of a dull red colour, but sometimes white. It was formerly used in hysteric cases, but is now fallen into disuse. The Swedes reckon it almost an universal remedy in the diseases of their cattle. Horses, cows, sheep, and goats refuse to eat it. There are five species.

BALLS, or *ballets*, in heraldry, a frequent bearing in coats of arms, usually denominated according to their colours, bezants, plates, hurts, &c.

BALLUSTRADE, a series or row of balusters, joined by a rail; serving as well for a rest to the elbows, as for a fence or enclosure to balconies, altars, staircases, &c.

BALNEUM, a term used by chymists to signify a vessel, filled with some matter, as sand, water, &c. in which another is placed that requires a more gentle heat than the naked fire. Thus balneum arenosum, called also balneum siccum, or sand heat, is when the cucurbit is placed in sand, in ashes, or filings of iron. Balneum mariæ, or maris,

is when the vessel, containing the ingredients to be distilled, &c. is put into a vessel of water, which is made to boil; so that no greater heat than that of boiling water can be communicated to the substance to be treated. And balneum vaporis, or vaporarium, is when two vessels are disposed in such a manner, that the vapour raised from the water contained in the lower, heats the matter contained in the upper. See CHYMISTRY.

BALSAM, or *native balsam*, an oily, resinous, liquid substance, flowing either spontaneously, or by means of incision, from certain plants of sovereign virtue in the cure of several disorders. There are many kinds of balsams, but the most remarkable are benzoin, storax, styrax, balsam of Peru, balsam of Tolu. They owe their most important properties to the resinous ingredient.

1. *Benzoin.* This substance is obtained from the styrax benzoin, a tree which grows in Sumatra, &c. It flows from incisions made in the trunk. Benzoin comes to Europe in large masses of a light brown colour with yellow specks. It is very brittle, and breaks vitreous. When rubbed it emits a fragrant odour, and when heated sufficiently lets the benzoic acid escape. It is soluble in alcohol, but insoluble in water. It is used chiefly to perfume apartments, and extract from it benzoic acid. It has not been examined by any modern chymist. Its specific gravity is 1.092. It is considered as a compound of resin and benzoic acid.

2. *Storax.* This substance is obtained by incision from the styrax officinale, a tree which grows abundantly in the islands of the Levant, and in Italy and France. The storax is sometimes in large masses, sometimes in small tears; it is brittle, and has a brown colour. It has an aromatic taste and fragrant smell. It is soluble in alcohol, and yields benzoic acid by the usual processes. It is composed apparently of benzoic acid and resin.

3. *Styrax.* This is a semifluid juice, used in medicine on the continent, though scarcely in Britain. Its natural history is but imperfectly known; but it is said to exude from a tree called by the natives *rosamallos*, which is cultivated in Arabia. Bouillon Lagrange has published an account of its properties. Its colour is greenish, and its taste aromatic, and its smell agreeable. It is easily volatilized by heat. When treated with water, its benzoic acid is dissolved, while the other constituent remains. It is totally soluble in alcohol, except the impurities. When exposed to air it becomes harder, and absorbs oxygen. Hence we may consider it as a combination of benzoic acid and an imperfect resin.

4. *Balsam of Peru.* This substance is obtained from the myroxylon peruiferum, which grows in the warm parts of South America. The tree is full of resin, and the balsam is obtained by boiling the twigs in water. It has the consistency of honey, a brown colour, an agreeable smell, and a hot acrid taste. Like the last it consists of benzoic acid and volatile oil, not completely converted into resin. Water dissolves part of the acid, alcohol the whole balsam. It is easily volatilized by heat.

5. *Balsam of Tolu.* This substance is obtained from the tolnifera balsamum, a tree which grows in South America. The balsam flows from incisions made in the bark. It comes to Europe in small gourd shells. It is of a reddish brown colour, and considerable consistence; and when exposed to the air, it becomes solid and brittle. Its smell is fragrant. The composition of this substance has not been ascertained. It is only from analogy that it has been put among the balsams. Mr. Hatchett's experiments on it are very curious and important. He has ascertained that the balsams in general are soluble in alkalies. When Tolu is dissolved in the smallest possible quantity of lixivium of potash, it completely loses its own odour, and assumes a most fragrant smell, somewhat resembling that of the clove pink. "This smell," Mr. Hatchett observes, "is not fugitive, for it is still retained by a solution which was prepared in June, and has remained in an open glass during four months." Mr. Hatchett found that it dissolved in nitric acid with nearly the same phenomena as the resins; but it assumed the odour of bitter almonds, which leads him to suspect the formation of prussic acid.

Such are the balsamic substances at present known. *Tar*, which has been sometimes placed among them, is obtained by a rude distillisation of the fir. Hence it contains a variety of ingredients, oil, resin, pyrolignous acid, water. When concentrated by heat it loses these volatile parts, and is converted into *pitch*; a substance which possesses the properties of resin.

BALSAMICS, in pharmacy, softening, restoring, healing, and cleansing medicines, of gentle attenuating principles, very friendly to nature. See PHARMACY.

BALTIMORA, in botany, a genus of the polygamia necessaria order and syngenesia class of plants. The receptaculum is chaffy; there is no pappus; the calyx is cylindrical and polyphillous; and the ray of the corolla is quinqueflorous. There is but one species, *viz.* baltimora recta, a native of Maryland.

BAMBOE, or *bambou*. See ARUNDO.

BAMBUSA, in botany. See ARUNDO.

BAN, in commerce, a sort of smooth, fine muslin, which the English import from the East Indies. The piece is almost a yard broad, and runs about twenty yards and a half.

BANANA, in botany. See MUSA.

BAND, in architecture, a general name for any flat, low member, or moulding, that is broad, but not very deep.

BAND *of pensioners*, are a company of 120 gentlemen, who receive a yearly allowance of 100*l.* for attending on his majesty on solemn occasions.

BAND is also the denomination of a military order in Spain, instituted by Alphonsus XI. king of Castile, for the younger sons of the nobility, who, before their admission, must serve ten years, at least, either in the army, or at court: and are bound to take up arms for the Catholic faith against the infidels.

BANDAGE, in surgery, a fillet, roller, or swathe, used in dressing and binding up wounds, restraining dangerous hæmorrhages, and in joining fractured or dislocated bones. See SURGERY.

BANDAL, or *bandle*, the name of a measure in the south of Ireland, which is something more than half a yard; but the coarse narrow linen is sold in the markets, on which account it is called *bandle cloth*.

BANDALEER, or *bandeleer*, in military affairs, a large leathern belt, thrown over the right shoulder, and hanging under the left arm; worn by the ancient musketeers, both for the sustaining of their fire arms, and for the carriage of their musket charges.

BANDE, or *inbend*, in heraldry, expresses the position of a lion, when he is placed diagonally in the shield.

BANDERET, a general, or one of the commanders in chief of the forces.

BANDEROLE, in heraldry, is a stream affixed by small lines or strings immediately under the crook, on the staff of a crosier, and folding over the staff.

BANDEROLL, a little flag, in form of a guidon, extended more in length than breadth, used to be hung out on the masts of vessels, &c. It is a name also for camp colours.

BANGUE, a species of opiate, in great use throughout the east for drowning cares, and inspiring joy.

BANIANS, a religious sect in the empire of the Mogul, who believe a metempsychosis, and will therefore eat no living creature, nor even kill noxious animals; but endeavour to release them when in the hands of others: whence the vulgar phrase *banian* day for a fast.

BANISHMENT, a kind of punishment, by which the guilty person is obliged to leave the realm.

There are two kinds of banishment; one voluntary and upon oath, the other upon compulsion, for some crime or offence; the former, properly called abjuration, is now ceased; the latter is chiefly enjoined by judgment of parliament, or other courts of justice.

By Magna Charta, none shall be outlawed, or banished his country, but by lawful judgment of his peers, according to the law of the land, 9 Hen. III. 29.

BANK, in commerce, a common repository, where many persons agree to keep their money, to be always ready at their call or direction: or certain societies or communities, who take the charge of other people's money, either to improve it, or to keep it secure.

There are banks of various kinds, and different in the nature of their constitutions and establishments: some are instituted wholly on the public account, and put under the direction of the magistrates, as the famous bank of Amsterdam, where the money deposited shall be always kept for the use of the proprietors, and shall never be let out for profit or advantage.

Payments made by assignments upon this bank are valued from three to six per cent. above the payment of the money in specie, arising from an opinion that the proprietors entertain of the equity of its administration; for judging themselves secure that their money lies always ready at hand, they seldom draw out large sums, but make their mutual payments by transferring the sums from one man's account to another.

A second sort of bank is such as consists of a company of monied men, who being duly established, and incorporated by the laws of their country, agree to deposite a certain considerable fund, or joint stock, to be employed for the use of the society; as lending money upon good security, buying and selling bullion, gold, and silver, discounting bills of exchange, &c. Such is the bank of England, which was established in the year 1694, with a capital of 1,200,000*l*. This they lent to government, for which eight per cent. interest was paid, and 4000*l*. per annum for charges of management. The corporation was entitled "The governor and company of the bank of England;" and their charter directed that there be a governor and twenty-four directors; it also lays down rules respecting the qualifications of voters and of directors, with other regulations. In 1697 the bank was allowed to enlarge its capital to 2,201,171*l*. 10*s*. for the purpose of supporting public credit, bank notes having been at twenty per cent. discount, owing to the want of punctuality in the payments of government. This capital was allowed to increase from time to time, till at Michaelmas, 1746, when the whole debt due to the bank from the public was 11,686,800*l*. and its divided capital has been raised to 10,780,000*l*.

From an early period after the establishment of the bank, it had been the practice of the company to assist government with money in anticipation of the land and malt taxes, and by making temporary advances on exchequer bills and other securities. In the year 1781, the sums thus lent to government amounted to upward of eight millions, in addition to the permanent debt of 11,686,800*l*. The company now sought a renewal of their charter, and offered to advance two millions on exchequer bills: this being agreed to, a call was made of eight per cent. on their capital, which was now increased from 10,780,000*l*. to 11,642,400*l*. the sum on which they divide at present.

The bank of England acts not only as an ordinary bank, but as a great engine of state. It receives and pays the greater part of the annuities which are due to the creditors of the public; it circulates exchequer bills; and it advances to government, as we have already seen, the annual amount of the land and malt taxes, which are frequently not paid up for some years. It discounts bills of merchants; and upon different occasions it has supported the credit of the principal houses, not only of England, but of Hamburgh and Holland.

The company is properly a trading company; and that which is peculiarly distinguished by the appellation of bank stock is a trading stock, the dividend of which, on a capital of 11,642,400*l*. paid half yearly, and now seven per cent. besides occasional bonuses, accrues from the annual income of the company; and this arises from the interest received for the money advanced by the proprietors to the public, or the permanent debt; from interest on annual temporary advances; from the profits of their dealings in bullion, and of their discounts; from the interest of stock held by the company; and from the sums allowed by government for the management of the annuities paid at the offices of the bank.

Such was also the bank of the United States of America.

There are indeed public banks established in most of the trading cities of Europe, as in Venice, Paris, Hamburgh, &c. The bank of Venice is the most ancient. It is established by a solemn edict of the commonwealth, which enacts, that all payments for wholesale merchandise, and letters of exchange, shall be in bank notes; that all debtors shall be obliged to carry their money to the bank, and all creditors receive their money from the bank; so that payments are performed by a simple transfer from the one person to the other. In matters of retail effective payments are sometimes made, which do not diminish, but rather augment the stock, in consequence of the liberty of withdrawing their money at pleasure, &c.

A third sort is the banks of private men, or partnerships, who deal in the same way as the former, upon their own single stock or credit; and such are the Lombard street, or other bankers, as they are called.

BANK, an elevation of the ground, or bottom of the sea, so as sometimes to surmount the surface of the water, or at least to leave it so shallow, as not to allow a vessel to remain afloat over it. Bank, in this sense, is much the same with flat, shoal, &c. There are banks of sand, and others of stone, called shelves and rocks. Sometimes the vapours at sea lead mariners to imagine that they see certain objects at a distance; these they call fog banks. The BANK denotes that of Newfoundland, celebrated for its cod fishery: it is more than two hundred miles long. Banks at sea are usually distinguished by a buoy, the colour of which is varied. Sand banks are denoted by light coloured buoys, and rocks by black ones.

BANK, in vessels moved with oars, is the bench on which the rowers are seated.

BANK denotes an elevation of earth, &c. to stop the waters, and prevent inundations.

BANKAFALET, a game at cards, which being cut into as many heaps as there are players, every man lays as much money on his own card as he pleases; and the dealer wins or loses as many as his card is superior or inferior to those of the other gamesters. The best card is the ace of diamonds; the next to it the ace of hearts; then the ace of clubs; and lastly, the ace of spades: and so of the rest of these suits in order, according to their degree. The cheat lies in securing an ace, or any other sure winning card; which are somehow marked, that the sharper may know them.

BANKER, in bricklaying, a piece of timber, six or eight feet long, and eight or nine inches square, on which they cut the bricks.

BANKRUPT, a trader, whom misfortune or extravagance has induced to commit an act of bankruptcy. The benefit of the bankrupt laws is allowed to none but *actual traders*, or such as buy and sell, and gain a livelihood by so doing.

Requisites to constitute a trading: the merchandising, or buying and selling, must be of that kind, whereby the party gains a credit upon the profits of an uncertain capital stock. Manufacturers, or persons purchasing goods or raw materials to sell again under other forms, or ameliorated by labour, as bakers, brewers, butchers, shoemakers, smiths, tanners, tailors, &c. are also within the statutes.

The following description of persons are not within the statutes of bankruptcy, *viz.* proprietors or persons having an interest in land, if buying and selling to whatever extent, for the purposes of disposing merely of the produce and profits of such land; graziers and drovers; owners of coal mines working and selling the coals; owners or farmers of alum rocks; farmers who make cheeses for sale, or those who sell cider made from apples of their own orchard. In all such cases, and others of a similar nature, where the several materials are purchased, and even some kind of manufacture exercised; yet as this is the necessary and customary mode of receiving the benefit arising from the land, such persons are not held to be traders within the statutes; nor are persons buying and selling bank stock or government securities. Buying or selling only will neither *singly* constitute trading; neither will a single act of buying *and* selling; or drawing or redrawing bills of exchange merely for the purpose of raising money for *private* occasions, and not with a view to gain a profit upon the exchange. Being a part owner in a ship, barge, or waggon, does *not constitute* a trader; nor holding a share or interest in a joint stock with others who trade, unless he share in the profit and loss upon the disposition of the capital. The merchandise must also be general, and not in a qualified manner only, as victuallers or innkeepers, schoolmasters, commissioners of the navy who victual the fleet by private contract, the king's butler, steward, or other officers; officers of excise or customs, sutlers of the armies, butlers, stewards of inns of court, clergymen, &c. as acting in such capacities *merely*, are not liable to be made bankrupts; the buying and selling in such cases not being general, but in the exercise of particular employments. Neither, upon the same principle, are receivers of the king's taxes, or persons discounting exchequer bills. If the parties above enumerated, however, are themselves within the bankrupt laws in any other respect, they will be liable to their operation, although they should evidently not profit by trading, or such trading should be illegal; although the trading should not be wholly carried on in England, buying only in England and selling beyond sea. Any person, native, denizen, or alien, residing in any part of the British dominions, or in foreign countries, though never a resident trader in England, yet if he is a trader, and coming to England commits an act of bankruptcy, he will be subject to the bankrupt laws.

No one can be a bankrupt on account of any debt which he is not compellable by law to discharge, as infants or married women. And if a single woman is a trader, and committing any act of bankruptcy, afterward marry, a commission issued against her after such marriage cannot be supported. But according to the custom of London, where a married woman is *sole trader*, she is held liable to a commission of bankruptcy like a *feme sole*.

Acts of bankruptcy. Departing the realm. This must be done with intent to defraud or delay creditors: when it appears that there was no such intention, it will not be a departure within the meaning of the statutes. 7 T. R. 509.

Departing from the dwelling house. Such departure must also be with intent to defraud *and delay* creditors; for the departure with an *intent* to delay, has been held insufficient, without *an actual* delay of some creditors. St. 803.

Beginning to keep the house; the being denied to a creditor who calls for money; but an *order* to be denied is not enough, without *an actual denial*, and that also to a creditor who has a debt demandable at the time. 5 T. R. 575.

Voluntary arrest, not only for a fictitious debt, but even for a just one, if done with the intent to delay creditors, is an act of bankruptcy.

Suffering an outlawry, with intent to defraud the creditors; but this will not make a man a bankrupt, if reversed before issuing a commission, or for default of proclamation after it, unless such *outlawry* was originally fraudulent.

Escaping from prison. Being arrested for a just debt of 100*l.* or upward, and escaping against the consent of the sheriff.

Fradulent procurement of goods to be attached or sequestered. A fradulent execution, though void against creditors, is not within the meaning of the words *attachment*, or *sequestration*, used in the statute; because they

relate only to proceedings used in London, Bristol, and other places.

Making any fraudulent conveyance. Any conveyance of property, whether total or partial, made with a view to defeat the claims of creditors, is a fraud, and if it be by deed, is held to be an act of bankruptcy.

A conveyance by a trader of all his effects and stock in trade by deed, to the exclusion of any one or more of his creditors, has been ever held to be an act of bankruptcy.

A mortgage, amongst other things, of all the stock in trade of a tradesman, was held to be an act of bankruptcy, as being an assignment of all the stock in trade, without which he could carry on no business.

A conveyance by a trader of part of his effects to a particular creditor carries no evidence whatever of fraud, unless made in contemplation of bankruptcy.

Being arrested for debt; lying in prison two months or more, upon that or any other arrest, or detention in prison for debt, will make the party a bankrupt, from the time of the first arrest; but where the bail is fairly put in, and the party at a future day surrenders in discharge of his bail, the two months are computed from the time of the surrender.

Of proceedings under a commission. The lord chancellor is empowered to issue a commission of bankrupt, and is bound to grant it as matter of right. By 5 Geo. II. c. 30. no commission can issue, unless upon the petition of a single creditor, to whom the bankrupt owes a debt which shall amount to 100*l.* the debt of two or more, *being partners*, shall amount to 150*l.* and of three or more to 200*l.*

If the debt against the bankrupt amounts to the sum required, it is not material, though the creditor should have acquired it for less.

If a creditor to the *full amount*, before an act of bankruptcy committed, receive after notice of the bankruptcy a part of his debt, such payment being illegal, cannot be retained, and the original debt remains in force, and will support a commission.

The debt must be a legal and not an equitable one, and if the legal demand be not in its nature assignable, the assignee cannot be the petitioning creditor, as the assignee of a bond.

If the creditor, for a debt at law, has the body of his debtor in execution, he cannot at the same time sue out a commission upon it; that being, in point of law, a satisfaction for the debt.

Of opening the commission. When the commissioners have received proof of the petitioning creditor's debt, the trading, and act of bankruptcy, they declare and adjudge the party a bankrupt. They are authorized to issue a warrant under their hands and seals, for the seizure of all the bankrupt's effects, books, or writings, and for that purpose to enter the house, or any other place belonging to the bankrupt.

Such debts only can be proved under a commission, as were either debts certainly payable, and which existed at the time of the bankruptcy, or which although originally contingent, yet, from the contingency happening before the bankruptcy, were become absolute. In every case the amount of the debt must be precisely ascertained.

Time and method of proving. Creditors were formerly precluded from proving after four months; but the court now, except in cases of gross negligence, allows them to come in at any time, whilst any thing remains to be disposed of. The usual proof required, is the oath of the creditor himself; either in person, or by affidavit if he live remote from the place of meeting, or reside in foreign parts. 5 Geo. II.

Corporations, or *companies*, are generally admitted to prove by a treasurer, clerk, or other officer duly authorized.

Of the assignees. Immediately after declaration of the bankruptcy, the commissioners are to appoint a time and place for the creditors to meet and choose assignees, and are directed to assign the bankrupt's estate and effects to such persons as shall be chosen by the major part in value.

The powers and duties of assignees are principally those of collecting the bankrupt's property, reducing the whole into ready money, and making distribution as early as possible. One assignee is not answerable for the neglect of another. Assignees, if they act improperly, are not only liable at law to the creditors for a breach of trust, but may be removed on account of misbehaviour, &c. by petitioning the lord chancellor. Upon the removal of an assignee, he is directed to join with the remaining one, in assignment to the latter and new assignee.

Provisions for wife, children, &c. By the statute of Eliz. the commissioners may assign any lands, &c. that the bankrupt shall have purchased jointly with his wife, and the assignment shall be effectual, against the bankrupt, his wife, or children; but this shall not extend to conveyances made before the bankruptcy *bona fide*, and not to the use of the bankrupt himself only, or his heirs, and where the parties to the conveyance are not privy to the fraudulent purposes to deceive the creditors.

Examination of the bankrupt. By the 5th Geo. II. the commissioners are empowered to examine the bankrupt, and all others, as well by parole, as by interrogations in writing. The said statute requires the bankrupt to discover all his estate and effects, and how, and to whom, and in what manner, on what consideration, and at what time, he has disposed of it; and all books, papers, and writings, relative thereto, of which he was possessed or interested, or whereby he or his family may expect any profit, advantage, &c. and on such examination he shall deliver up to the commissioners all his effects, (except the necessary wearing apparel of himself, his wife, and children,) and all books, papers, and writings, relating thereto.

With respect to his privilege from arrest. By the above act, the bankrupt shall be free from all arrest in coming to surrender, and from his actual surrender to the commissioners for and during the forty-two days, or the further time allowed to finish his examination, provided he was not in custody at the time of his surrender.

Books and papers. By 5 Geo. II. c. 30. the bankrupt is entitled, before the expiration of the forty-two days, or enlarged time, to inspect his books and papers, in the presence of the assignees, or some person appointed by them, and make such extracts as he shall deem necessary.

Power of commissioners in case of contumacy. The statutes empower the commissioners to enforce their authority by commitment of the party, in the following cases: persons refusing to attend on the commissioners' summons; refusing to be examined, or to be sworn, or to

sign and subscribe their examination, or not fully answering to the satisfaction of the commissioners.

Of the certificate. By the 5 Geo. II. a bankrupt surrendering, making a full discovery, and in all things conforming to the directions of the act, may with the consent of his creditors obtain a certificate. If the commissioners certify his conformity, and the same be allowed by the lord chancellor, his person, and whatever property he may afterward acquire, will be discharged and exonerated from all debts owing by him at the time he became a bankrupt. But no bankrupt is entitled to the benefit of the act, unless *four parts in five*, both in number and value of his creditors, who shall be creditors for not less than 20*l.* respectively, and who shall have duly proved their debts under the commission, or some other person duly authorized by them, shall sign the certificate.

Of the dividends. The assignees are allowed four months from the date of the commission to make a dividend; and should apply to the commissioners to appoint a meeting for that purpose, or they may be summoned by them to show cause why they have not done so.

Allowance to the bankrupt. Every bankrupt surrendering, and in all things conforming to the directions of the act, shall be allowed five per cent. out of the nett produce of his estate, provided, after such allowance, it be sufficient to pay his creditors ten shillings in the pound, and that the said five per cent. shall not in the whole exceed 200*l.* Should his estate in like manner pay 12*s.* 6*d.* in the pound, he shall be allowed seven and a half per cent. so as not to exceed 250*l.* and if his estate pay 15*s.* in the pound, he shall be allowed ten per cent. so as not to exceed 300*l.* But the bankrupt is not entitled to such allowance, till after a second dividend, nor can he be entitled to it till he has received his certificate.

Of the surplus. The commissioners are, on request of a bankrupt, to give a true and particular account of the application and disposal of his estate, and to pay the overplus, if any, to the bankrupt.

Of superseding commissions. Commissions may be superseded for the want of a sufficient debt of the petitioning creditor, or because he was an infant, or for want of sufficient evidence of the trading or act of bankruptcy, or in cases of fraud, or by agreement or consent of the creditors.

Joint commissions. Partners are liable to a joint commission, or individually, against each; but a joint and separate commission cannot in point of law be concurrent. A joint commission must include all partners; if there be three partners, and one of them an infant, there can neither be a commission against the three, nor against the other two.

Felony of bankrupts. If any person, who shall be duly declared a bankrupt, refuse, within forty-two days after notice left at his place of abode, and in the London Gazette, to surrender himself to the commissioners, and to fully disclose and discover all his estate and effects, real and personal, and all transferences thereof, and also all books, papers, and writings, relating thereto; and deliver up to the said commissioners, all such estate and effects, books, papers, &c. as are in his power, except his necessary wearing apparel, &c. or in case he shall conceal, or embezzle, any part of his estate, real or personal, to the value of 20*l.* or any books of accounts, papers, or writings, relating thereto, with *intent to defraud his creditors*, being lawfully convicted thereof, by judgment or information, he shall be adjudged guilty of felony, without benefit of clergy, and his goods divided amongst his creditors. 5 Geo. II. c. 30.

BANKSIA, in botany, a genus of the monogynia order, belonging to the tetandria class of plants. The amentum is scaly, the corolla consists of four petals; the antheræ are in the cavity of the folds, and sessile; the capsule is bivalvular; and the seed is solitary and bipartite. There are eight species, all greenhouse plants, and natives of New Holland.

BANN, or Ban, in the feudal law, a solemn proclamation or publication of any thing. Hence the custom of asking, or bans, before marriage.

Bann, in military affairs, a proclamation made in the army by beat of drum, sound of trumpet, &c. requiring the strict observance of discipline, either for the declaring a new officer, or punishing an offender. At present such kind of proclamations are given out in the written orders of the day.

Bann *of the empire*, an imperial proscription, being a judicial punishment, wherewith such as are accessary in disturbing the public peace are judged unworthy of the immunities and protection of the empire, and are outlawed or banished, &c.

BANNER. We find a multiplicity of opinions concerning the etymology of this word; some deriving it from the Latin bandum, a band or flag; others, from the word bann, to summon the vassals to appear in arms; others, again, from the German ban, a field or tenement, because landed men alone were allowed a banner; and, finally, there are some who think it is a corruption of panniere, from pannus, cloth, because banners were originally made of cloth.

Banner, the ordnance flag fixed on the fore part of the drum major's kettle drum carriage of the royal artillery.

Banner, in the horse equipage, for the kettle drums and trumpets, must be of the colour of the facing of the regiment. The badge of the regiment, or its rank, to be in the centre of the banner of the kettle drums, as on the second standard. The king's cypher and crown to be on the banner of the trumpets, with the rank of the regiment in figures underneath. The depth of the kettle drum banners to be three feet six inches; the length four feet eight inches, excluding the fringe. Those of trumpets to be twelve inches in depth, and eighteen inches in length.

BANNERET, an ancient order of knights, or feudal lords, who possessing several large fees, led their vassals to battle under their own flag, when summoned thereto by the king. This order never was conferred but upon some heroic action performed in the field. Anciently there being but two kinds of knights, great and little, the first were called bannerets, the second bachelors; the first composed the upper, the second the middle nobility. Till lately we have had none of this order created in England since the time of king Charles the First; the late sir William Erskine, however, on his return from the continent in 1764, was made a knight banneret, in Hyde park, by his present majesty, in consequence of his distinguished conduct at the battle of Emsdorff. But he was not acknowledged as such in this country, although he was invested with the order between the two standards of the

fifteenth regiment of light dragoons, because the ceremony did not take place where the engagement happened. Captain Trollope, of the royal navy, is the last created knight banneret. Knights banneret take precedence next to knights of the bath.

The form of the banneret's creation was this: on a day of battle, the candidate presented his flag to the king, or general, who cutting off the train or skirt thereof, and making it a square, returned it again; the proper banner of bannerets, who from hence are sometimes called knights of the square flag.

BANNEROLS, in heraldry, are small flags used at funerals.

BANNISTERIA, in botany; a genus of the trigynia order, and decandria class of plants; and in the natural method ranking under the 23d order, trihilatæ. The calyx is quinquepartite, with nectareous pores on the outside of the base; the petals are roundish and ungulated; the seeds are three, with membranaceous wings. There are 24 species, all natives of warm countries, but possessing no remarkable properties.

BANNIMUS, the form of expulsion of any member from the university of Oxford, by affixing the sentence up in some public place, as a denunciation of it.

BANQUET, in the manege, that small part of the branch of a bridle that is under the eye.

Banquet line, an imaginary line drawn, in making a bit, along the banquet, and prolonged up or down, to adjust the designed force or weakness of the branch, in order to make it stiff or easy.

Banquet, or Banquette, in fortification, a little foot bank, or elevation of earth, forming a path, which runs along the inside of a parapet, upon which the musketeers get up, in order to discover the counterscarp, or to fire on the enemy in the moat, or in the covert way.

BANTAM WORK, a kind of painted or carved work, resembling that of Japan, only more gaudy.

There are two sorts of Bantam as well as Japan work: as in the latter, some are flat, and others embossed; so in Bantam work some are flat, and others cut in, or carved into the wood. The Japan artists work in gold and other metals, and the Bantam generally in colours, with a small sprinkling of gold.

BAPTES, a name given by the ancients to a fossil substance used in medicine: it was soft and of an agreeable smell, and probably one of the bitumens.

BAR, in courts of justice, an enclosure made with a strong partition of timber, where the counsel are placed to plead causes. Hence our lawyers, who are called to the bar, or licensed to plead, are termed barristers, an appellation equivalent to licentiate in other countries.

Bar, in law, a plea of a defendant, which is said to be sufficient to destroy the plaintiff's action. It is divided into bar special, bar to common intendment, bar temporary, and bar perpetual. Bar special, falls out upon some special circumstances of the case in question, as where an executor being sued for his testator's debt, pleads that he had no goods in his hands at the day on which the writ was sued out. Bar to common intendment is a general bar, which commonly disables the plaintiff's declaration. Bar temporary is such as is good for the present, but may afterward fail; and bar perpetual is that which overthrows the plaintiff's action for ever. In personal actions, once barred and ever so, is the general rule; but it is intended, where a bar is to the right of the cause, not where a wrong action is brought.

Bar, in heraldry, an ordinary in form of the fess, but much less. It differs from the fess only in its narrowness, and in this, that the bar may be placed in any part of the field, whereas the fess is confined to a single place.

Bar, in the manege, the highest part of that place of a horse's mouth situated between the grinders and tushes.

Bar, a stroke drawn perpendicularly across the lines of a piece of music, including between each two a certain quantity or measure of time, which is various, as the time of the music is either triple or common. In common time, between each two bars is included the measure of four crotchets; in triple, three. The principal use of bars is to regulate the beating of time in a concert.

Bar, in hydrography, denotes a bank of sand, or other matter, whereby the mouth of a river is in a manner choked up.

BARALIPTON, among logicians, a term denoting the first indirect mode of the first figure of syllogisms. A syllogism in baralipton, is when the two first propositions are general, and the third particular, the middle term being the subject in the first proposition, and the predicate in the second. Thus:

Every evil ought to be feared:
Every violent passion is an evil:
Therefore something that ought to be feared is a violent passion.

BARALLOTS, a sect of the Manicheans at Bologna in Italy, who had all things in common, even their wives and children.

BARANGI, officers among the Greeks of the lower empire. Cujas calls them in Latin protectores, and others give them the name of securigeri. It was their business to keep the keys of the city gates where the emperor resided.

BARATHRUM, in antiquity, a deep dark pit at Athens, into which condemned persons were cast headlong. It had sharp spikes at the top, that no man might escape out, and others at the bottom to pierce and torment such as were cast in.

The term is also applied to certain baleful caverns, inaccessible on account of their fetid or poisonous fumes.

BARBACAN, or Barbican, a watch tower, for the purpose of descrying an enemy at a great distance: it also implies an outer defence, or sort of ancient fortification to a city or castle, used especially as a fence to the city or walls; also an aperture made in the walls of a fortress to fire through upon the enemy. It is sometimes used to denote a fort at the entrance of a bridge, or the outlet of a city, having a double wall with towers.

BARBADOES TAR. See Bitumen.

BARBICAN, in architecture, a canal, or opening left in the wall for water to come in and go out, when buildings are erected in places liable to be overflowed, or to drain off the water from a terrace, or the like.

BARBARA, among logicians, the first mode of the first figure of syllogisms.

A syllogism in barbara, is one of which all the propositions are universal, and affirmative; the middle term being the subject of the first proposition, and attribute in the second. For example,

Bar. Every wicked man is miserable;
Ba. All tyrants are wicked men;
Ra. Therefore all tyrants are miserable.

BARBATED *leaf*, one terminated by a bunch of strong hairs.

BARBE, in commerce, a Barbary horse, greatly esteemed for its beauty, strength, and swiftness.

BARBE, in the military art: to fire in barbe means to fire the cannon over the parapet instead of firing through the embrasures; in which case the parapet must not be above three feet and a half high.

BARBE, or *Barde*, is an old word denoting the armour of the horses of the ancient knights and soldiers.

BARBED and CRESTED, in heraldry, an appellation given to the combs and gills of a cock, when particularized for being of a different tincture from the body.

A barbed cross is a cross, the extremities of which are like the barbed irons used for striking of fish.

BARBELICOTÆ, in church history, a sect of gnostics, who affirmed that an immortal eon had commerce with a virgin called Barbelath, to whom he granted successively the gift of prophecy, incorruptibility, and eternal life.

BARBER, one who makes a trade of shaving, or trimming, the beards of other men, for money. Besides curling the hair, and shaving, the ancient barbers trimmed the nails. Formerly some musical instrument was part of a barber's stock in trade; and it was customary for persons above the common rank to resort to his shop, either for surgical operations, or for shaving, &c. The music was for the amusement of the waiting customers, and answered the same purpose as a newspaper in modern times. Barbers were uniformly bleeders; and the *pole* now used as a sign, was a representation of the staff which was put into the hand of a person undergoing the operation of phlebotomy. The white band which surrounds it is designed to represent the fillet that binds up the arm. The surgeon barbers were incorporated by Henry the VIIIth, and separated from the surgeons by an act of Anne.

BARBET, in ornithology, the name of a *genus* of birds in Latham's Synopsis, corresponding with the bucco of Linnæus. Barbets are described as a dull stupid race of birds, inhabiting the tropical climates. They probably take their name from the strong bristles which surround the bill. They are in general larger than a lark, and vary in plumage, being black, green, reddish, pied, &c. See Bucco.

BARBING, is sometimes used for shearing: by an ancient statute, cloth was not to be sold, till barbed, rowed, and shorn.

BARBLES, or BARBS, in farriery, the knots of superfluous flesh that grow up in the channels of a horse's mouth, that is, in the intervals that separate the bars, and lie under the tongue.

BARCALON, an appellation given to the prime minister of the king of Siam.

BARCONE, a short and broad vessel used in the Mediterranean for the carriage of corn, salt, and other provisions, from one place to another.

BARDESANISTS, Christians of the second century, who maintained that the devil was a self existent independent being; that Jesus Christ was not born of a woman, but brought his body with him from heaven; and denied the resurrection of the body.

BAREGE *waters*, are celebrated for their mineral virtues: they are situated at Barege on the French side of the Pyrenes, and differ in the degree of temperature from 120 degrees, to 73 degrees. By analysis they are found to contain sulphurated hydrogen and soda, some common salt, and a bitumen. See MINERAL WATERS.

BAR FEE, a fee of twenty pence, which every prisoner acquitted of felony pays to the gaoler.

BARGAIN and Sale. See CONTRACT.

BARGE COURSE, with bricklayers, a term used for that part of the tiling which projects over without the principal rafters, in all sorts of buildings, where there is either a gable or kirkin head.

BARGHMOTE, a court which takes cognisance of causes and disputes between miners. By custom of the mines, no person is to sue a miner for ore, debt, &c. but in this court, on penalty of forfeiting the debt, and paying the charge at law.

BARILLA, a kind of Spanish alkaline salt used in the glass trade. It is procured by burning to ashes several plants of the kali kind. It is brought over in brown speckled masses, without smell and strongly alkaline. See SODA.

BARK, in the anatomy of plants, the exterior part of trees, corresponding to the skin of an animal. See PHYSIOLOGY of PLANTS.

BARK, in navigation, a little vessel with two or three triangular sails; but, according to Guillet, it is a vessel with three masts, *viz.* a mainmast, foremast, and mizenmast.

BARK, or Jesuit's Bark. See CINCHONA.

BARK BED, in gardening, that sort of hot bed, which is wholly or principally constituted of tanner's bark, commonly employed in a hot house, because it retains its heat longer and emits less steam than a hot bed of horse dung.

BARK BOUND, a disease in trees thought to be capable of being cured by making a slit or opening through the bark.

BARK LONGUE, or Barca Longa, a small low sharp built but very long vessel, without a deck. It goes with sails and oars, and is very common in Spain.

BARLERIA, a genus of the angiospermia order, and didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The calyx is quadripartite; two of the stamina are much less than the rest: the capsule is quadrangular, bilocular, bivalved, elastic, and without claws; and the seeds are two. There are eleven species; all natives of the warm parts of America, and therefore require to be kept in a stove, and treated like other tender exotics. They possess no great beauty nor any remarkable property; but are kept for the sake of variety.

BARLEY. See HORDEUM.

BARLEYCORN, the least of our long measures, being the third of an inch.

BARLEY, *pearl*, and *French* BARLEY, are barley freed from the husk, and rounded by a mill; the distinction between the two being that the *pearl* barley is reduced to the size of small shot, all but the heart being ground away.

BARM. See YEAST.

BARNABITES, a religious order, founded in the sixteenth century, by three Italian gentlemen, who had been advised by a famous preacher of those days to read carefully the epistles of St. Paul. Hence they were called

clerks of St. Paul, and Barnabites, because they performed their first exercise in a church of St. Barnabas at Milan. Their habit is black, and their office is to instruct, catechise, and serve in mission.

BARNACLE, or BERNICLE, in ornithology. See ANAS.

BARNACLES, in farriery, an instrument composed of two branches joined at one end with a hinge, to put upon horses' noses when they will not stand quietly to be shod, blooded, or dressed.

BARNADESIA, in botany; a genus of the polygamia æqualis order, and syngenesia class of plants; the characters of which are: the corolla is radiated; the calyx is naked, imbricated, and pungent; the pappus of the rays feathery, of the disk bristly and retrofracted. There is but one species, *viz.*

Barnadesia Spinosa, a native of South America.

BAROCO, in logic, a term given to the fourth mode of the second figure of syllogisms. A syllogism in baroco has the first proposition universal and affirmative, but the second and third particular and negative, and the middle term is the predicate in the two first propositions. For example:

Every virtue is attended with discretion;
Some kinds of zeal are not attended with discretion;
Therefore some kinds of zeal are not virtues.

BAROMETER, a machine for measuring the weight of the atmosphere. The barometer is founded on an experiment of Torricelli, who considering that a column of water of about thirty-three feet was equal in weight to a column of air of the same base, concluded that a column of mercury, no longer than about twenty-nine inches and a half, would be so too, such a column of mercury being as heavy as thirty-three feet of water. Accordingly he tried the experiment, and the apparatus he made use of is now the common barometer or weather glass.

The tubes of which barometers are made ought to be at least one fourth of an inch bore; but one third or even one half of an inch is better. The tube should be new, and perfectly clean within. In order to this, it should be hermetically sealed at both ends, at the glasshouse, when made; one of the ends may be cut off with a file, when you use it. The mercury ought to be perfectly pure, and should be purged from air by boiling it in a tube.

To fill the tube with mercury, warm it, and pour some mercury into it by a small paper funnel, so as to reach within an inch of the top; you will see that as the tube fills, there are bubbles of air in several parts. When the tube is full, apply your finger hard against the open end, and invert it; by which means the air that was on the top, now rising through all the quicksilver, gathers every bubble in its way. Turn the tube up again, and the bubble of air reascends; and, if there are many small bubbles left, carries them away. If, however, any remain, the operation must be repeated. The tube is now to be filled to the top, and stopping the open end with the finger, must be inverted into a basin of mercury. When the end of the tube is perfectly plunged under the surface of the mercury, the finger must be taken away, and the mercury in the tube will subside, remaining suspended at the height of 29 or 30 inches, according to the pressure of the atmosphere at the time. The space at the top of the tube is a perfect vacuum.

The following is a still better way of filling the tube: Pour the purest mercury into the tube, which must be very dry and well cleaned, to within two inches of the top, and then hold it with the sealed end lowest, in an inclined position, over a chafingdish of burning charcoal, placed near the edge of a table, in order that all parts of the tube may be exposed successively to the action of the fire, by moving it obliquely over the chafingdish. The sealed end is to be first gradually presented to the fire. As soon as the mercury becomes hot, the internal surface of the tube will be studded with an infinite number of air bubbles, giving the mercury a kind of gray colour: these increase in size by running into one another, and ascend toward the higher parts of the tube, where, meeting with a cooler part of the fluid, they are condensed, and nearly disappear. In consequence, however, of successive emigrations toward the upper parts of the tube, which are successively heated, they finally acquire a bulk, which enables them in their united form entirely to escape. When the first part of the tube is sufficiently boiled, move it onward, by little and little, through its whole length. When the mercury boils, its parts strike against each other, and against the sides of the tube, with such violence, that a person unacquainted with the operation, naturally apprehends the destruction of his tube. By this process the mercury is entirely deprived of the air which adhered to it.

The tube is now fixed with its basin to a wooden frame prepared for it, having a scale of inches at the upper end, which is accurately measured from the surface of the mercury in the cistern. Plate XIV. Miscel. fig. 6. Fig. 7 shows the scale or vernier at the top, drawn larger.

This is the common construction of the barometer, and is still found to be the best. However, as the space through which the upper part of the mercury in the tube has to rise and fall does not exceed three inches, from 28 inches to 31 above the mercury in the basin, several contrivances have been used to increase the scale, and thereby show more sensibly small changes; the chief of which are the following:

The diagonal barometer. A B C, fig. 8, is a tube sealed at C, immersed in mercury at A; this tube is perpendicular from A to B, where the scale of variation begins; thence it is bent into B C. This part B C proceeds to the highest limit in the scale of variation, *viz.* I C; and consequently, while the mercury rises from I to C in the common barometer, it will move in this from B to C; and so the scale will be by this means enlarged in the proportion of B C to I C.

This form however, being subject to a great degree of friction, on account of the obliquity in the part B C, which inclination makes the quicksilver frequently divide into several parts, it requires the trouble of filling tubes anew too often.

The horizontal, or rectangular barometer, consists of a tube A C D F, fig. 9, sealed on the upper end A, and bent to a right angle at D. The mercury stands in both legs from E to C. Here it is evident, that in moving three inches from A to C, it will move through so many times three inches in the small leg D F, as the bore of D F is less than the bore of A C, whence the motion of the mercury at E must be extremely sensible. This form is liable to the same exceptions as remarked in that of fig. 8; and, besides a great degree of friction, and the frequent breaking off of the mercury in the leg E, the part D F being a very small

bore, the free motion of the mercury must be impeded by the attraction of cohesion.

The wheel barometer. A, fig. 10, represents the quicksilver in a glass tube, having a large round head or ball, and turned up at bottom B; upon the surface of the mercury in the recurved leg, there is then placed a short glass tube loaded with mercury, with a string going over a pulley, and is balanced by another weight hanging freely in the air. As the surface at A is very large, and that at B very small, the motion of the quicksilver and consequently of the ball, will at the bottom be very considerable; but as the weight moves up and down, it turns the pulley, and that a hand or index; and by the divisions of a large graduated circle, the minutest variations of the air are plainly shown, if the instrument is accurately made, and the friction of the several parts inconsiderable.

There is also a barometer, contrived so as not to be affected by the motion of a ship, called the marine barometer.

Also a portable barometer, for moving from place to place without injury; and for measuring the heights of mountains, by observing the difference of the altitude of the mercury at the bottom and top of the mountain.

A thermometer should always be attached to the barometer, as a necessary appendage; and by the side of it a scale of correction, to show how much to add or subtract from the height of the mercury in the barometer for the degree of temperature; for it is evident that the mercury in the tube will be affected by heat and cold in the same manner as the thermometer, and on that account it will not show the true weight of the atmosphere. This correction is, therefore, very necessary.

Ever since it was observed that a change of weather generally accompanied or followed a variation in the height of the barometer, it has been used as a prognostic of the weather. A great variety of observations have been made by different people, relative to the effect which certain changes of weather have upon this instrument; and thence they have derived a system of rules, to enable any one to know what change will happen in the weather, by knowing the alteration that has taken place in the height of the mercury.

Before we proceed to mention the rules, which are the result of the long observation and experience of philosophers, it is necessary to observe, that they are by no means so certain, and so much to be depended upon, as many people suppose. So numerous are the causes that affect the state of the atmosphere, with which we are but little acquainted, that no single instrument can point out with precision the alterations likely to happen. Besides the barometer, there are several other instruments used for meteorological purposes, such as the thermometer, hydrometer, wind gage, rain gage, electrometer, &c. with which we shall become acquainted in their turn. To be best enabled to prognosticate the change of weather, accurate observations ought to be made with all these instruments, aided by considerable experience and the knowledge of natural philosophy and chymistry; and even then, it requires more science than we are possessed of, to predict with certainty the alterations of the weather. See METEOROLOGY.

As the barometer, however, is the most useful of these, and as it undoubtedly affords us considerable assistance, we shall lay down such directions as are most approved of for this purpose.

1. The rising of the mercury presages, in general, fair weather; and its falling, foul weather; as rain, snow, high winds, and storms. 2. In very hot weather, the falling of the mercury foretells thunder. 3. In winter, the rising presages frost; and in frosty weather, if the mercury falls three or four divisions, there will certainly follow a thaw. But in a continued frost, if the mercury rises, it will certainly snow. 4. When foul weather happens soon after the falling of the mercury, expect but little of it; and, on the contrary, expect but little fair weather, when it proves fair shortly after the mercury has risen. 5. In foul weather, when the mercury rises much and high, and continues so for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow. 6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes, then expect a great deal of wet, and probably high winds. 7. The unsettled motion of the mercury denotes uncertain and changeable weather. 8. You are not so strictly to observe the words engraved on the plates, though in general it will agree with them, as the mercury's rising and falling; for if it stands at much rain, and then rise up to changeable, it presages fair weather; though not to continue so long as if the mercury had risen higher; and, on the contrary, if the mercury stood at fair, and falls to changeable, it presages foul weather; though not so much of it as if it had sunk lower.

From these observations it appears, that it is not so much the height of the mercury in the tube that indicates the weather, as the motion of it up and down; wherefore, in order to form a right judgment of what weather is to be expected, we ought to know whether the mercury is actually rising or falling; to which end, the following rules are of use:

1. If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides, it is generally a sign that the mercury is then rising. 2. If the surface is concave, it is then sinking. And, 3. if it is level, the mercury is stationary, or rather, if it is a little convex; for mercury, being put into a glass tube, especially a small one, will naturally have its surface a little convex, because the particles of mercury attract one another more forcibly than they are attracted by glass. If the glass is small, shake the tube; and then if air is grown heavier, the mercury will rise about half the tenth of an inch higher than it stood before; if it is grown lighter, it will sink as much. This proceeds from the mercury's sticking to the sides of the tube, which prevents the free motion of it until it is disengaged by the shock; and therefore, when an observation is to be made by such a tube, it ought always to be shaken first; for sometimes the mercury will not vary of its own accord, until the weather it ought to have indicated is present.

Here we must observe, that the above mentioned phenomena are peculiar to places lying a considerable distance from the equator; for in the torrid zone, the mercury in the barometer seldom either rises or falls much. In Jamaica, it is observed by sir William Beeston, that the mercury in the morning constantly stood at one degree

below changeable, and at noon sunk to one degree above rain; so that the whole scale of variation there was only three tenths of an inch. At St. Helena, too, where Dr. Halley made his observations, he found the mercury to remain almost stationary, whatever weather happened. Of these phenomena, their causes, and why the barometer indicates an approaching change of weather, the doctor gives us the following account:

1. In calm weather, when the air is inclined to rain, the mercury is commonly low. 2. In serene, good, and settled weather, the mercury is generally high. 3. Upon very violent winds, though they are not accompanied with rain, the mercury sinks lowest of all, with relation to the point of the compass the wind blows upon. 4. The greatest heights of the mercury are found upon easterly or northeasterly winds. 5. In calm frosty weather, the mercury generally stands high. 6. After very great storms of wind, when the mercury has been very low, it generally rises again very fast. 7. The more northerly places have greater alterations of the barometer than the more southerly. 8. Within the tropics, and near them, according to the accounts we have had from others, and the observations made at St. Helena, the changes of the weather made very little or no variation in the height of the mercury.

Hence it is thought that the principal cause of the rise and fall of the mercury is from the variable winds which are found in the temperate zone, and whose great inconstancy in England is notorious.

A second cause is, the uncertain exhalation and precipitation of the vapours lodging in the air, whereby it is at one time much more crowded than at another, and consequently heavier; but this latter depends in a great measure upon the former. Now, from these principles we may explain the several phenomena of the barometer, taking them in the same order as they are laid down. Thus,

1. The mercury being low, indicates rain; because the air being light, the vapours are no longer supported by it, being become specifically heavier than the medium in which they floated; so that they descend toward the earth, and, in their fall, meeting with other aqueous particles, they incorporate together, and form little drops of rain: but the mercury's being at one time lower than another, is the effect of two contrary winds blowing from the place where the barometer stands; whereby the air of that place is carried both ways from it, and consequently the incumbent cylinder of air is diminished, and accordingly the mercury sinks: as, for instance, if in the German Ocean it should blow a gale of westerly wind, and at the same time an easterly wind in the Irish Sea; or if in France, it should blow a northerly wind, and in Scotland a southerly; it must be granted, that that part of the atmosphere impendent over England would be exhausted and attenuated, and the mercury would subside, and the vapours which before floated in these parts of the air of equal gravity with themselves, would sink to the earth.

2. The greater height of the barometer is occasioned by two contrary winds blowing toward the place of observation, by which the air of other places is brought thither and accumulated; so that the incumbent cylinder of air being increased both in height and weight, the mercury pressed by it must needs stand high, as long as the winds continue so to blow; and then the air being specifically heavier, the vapours are kept suspended, so that they have no inclination to precipitate, and fall down in drops which is the reason of the serene good weather which attends the greater heights of the mercury.

3. The mercury sinks the lowest of all by the very rapid motion of the air in storms of wind. For the tract or region of the earth's surface, in which the winds rage, not extending all round the globe, that stagnant air which is left behind, as likewise that on the sides, cannot come in so fast as to supply the vacuity made by so swift a current; so that the air must necessarily be attenuated when and where the winds continue to blow, and that more or less, according to their violence: add to which, that the horizontal motion of the air being so quick, may in all probability take off some part of the perpendicular pressure; and the great agitation of its particles is the reason why the vapours are dissipated, and do not condense into drops, so as to form rain, otherwise the natural consequence of the air's rarefaction.

4. The mercury stands highest upon the easterly and northeasterly wind; because, in the great Atlantic Ocean, on this side the thirty-fifth degree of north latitude, the winds are almost always westerly or southwesterly; so that, whenever here the wind comes up at east and northeast, it is sure to be checked by a contrary gale as soon as it reaches the ocean; wherefore, according to the second remark, the air must needs be heaped over this island, and consequently the mercury must stand high as often as these winds blow. This holds true in this country; but is not a general rule for others, where the winds are under different circumstances: and we have sometimes had the mercury here so low as 29 inches, upon an easterly wind, but then it blew exceedingly hard; and thus is accounted for, what was observed in the third remark.

5. In calm frosty weather, the mercury generally stands high, because it seldom freezes but when the winds come out of the northern and northeastern quarters, or at least, unless those winds blow at no great distance off; for the northern parts of Germany, Denmark, Sweden, Norway, and all that tract whence northeastern winds come, are subject to almost continual frost through the winter, and thereby the lower air is very much condensed, and in that state is brought hitherward by those winds; and, being accumulated by the opposition of the westerly wind blowing in the ocean, the mercury must needs be forced to a more than ordinary height; and, as a concurring cause, the shrinking of the lower parts of the air into lesser room, by cold, must cause a descent of the upper parts of the atmosphere, to reduce the cavity made by this contraction to an equilibrium.

6. After great storms, when the mercury has been very low, it generally rises again very fast. It has been observed to rise one inch and a half in less than six hours, after a long continued storm of southwest wind. The reason is, that the air being very much rarefied by the great evacuation which such continued storms make of that fluid, the neighbouring air runs in the more swiftly to bring it into an equilibrium.

Lastly. The variations are greater in the more northerly places.

BARON, a degree of nobility next below a viscount, and above a baronet. It is probable that formerly all those were barons who had lordships with courts baron, and soon

after the Conquest all such sat in the house of peers; but being very numerous, it grew an order and custom, that none should sit but such as the king thought fit to call up by writ, which ran pro hac vice tantum. This state of nobility being very precarious, they at length obtained of the king letters patent, and these were called barons by patent, or creation; the only way now in use of making barons, unless when the son of a lord, in his ancestor's life time, is summoned by writ.

Barons *of the cinque ports* are members of the house of commons, elected by the five ports, two for each port.

Those who have been mayors of Corfecastle in Dorsetshire are also denominated barons; as were formerly the principal citizens of London.

Baron and Feme, in our law, a term used for the husband and wife; and they are deemed but one person, so that a wife cannot be witness for or against her husband, nor he for or against his wife, except in cases of high treason.

Baron and Feme, in heraldry, is when the coats of arms of a man and his wife are borne per pale in the same escutcheon, the man's being always on the dexter side, and the woman's on the sinister.

BARONET, a modern degree of honour, which is hereditary, and has the precedence of all knights, except those of the garter, bannerets, and privy counsellors.

Baronets *of Ireland*, an hereditary dignity instituted in 1619. There are also baronets of Nova Scotia, an order instituted by Charles I. in 1625.

BARONY, the honour and territory which gives title to a baron, whether he is a layman or a bishop.

Barony, in Ireland, the name of the divisions of the counties, answering to English hundreds.

BARRA, in commerce, a long measure used in Portugal and some parts of Spain, to measure woollen cloths, linen cloths and serges.

BARRATOR, in law, a common mover or maintainer of suits and quarrels, either in courts or elsewhere in the country. A man cannot be adjudged a barrator for bringing any number of suits in his own right, though they are vexatious. Barrators are punished by fine and imprisonment. 4 Blacks. 134.

BARRATRY, in a ship master, is his cheating the owners. If goods delivered on ship board are embezzled, all the mariners ought to contribute to the satisfaction of the party that lost his goods, by the maritime law; and the cause is to be tried in the admiralty.

BARREL, a measure of liquids. The English barrel, wine measure, contains the eighth part of a tun, the fourth part of a pipe, and one half of an hogshead; that is to say, it contains thirty-one gallons and a half: a barrel, beer measure, contains thirty-six gallons. The barrel of beer, vinegar, or liquor preparing for vinegar, ought to contain thirty-four gallons, according to the standard of the ale quart.

Barrel, also denotes a certain weight of several merchandises, which differs according to the several commodities: a barrel of Essex butter weighs one hundred and six pounds, and of Suffolk butter, two hundred and fifty-six pounds. The barrel of herrings ought to contain thirty-two gallons wine measure, which amount to about twenty-eight gallons old standard, containing about a thousand herrings. The barrel of salmon must contain forty-two gallons. The barrel of eels the same. The barrel of soap must weigh two hundred and fifty-six pounds.

Barrel, in anatomy, a pretty large cavity behind the tympanum of the ear, about four or five lines deep, and five or six wide.

Barrels, *thundering*, in the military art, are filled with bombs, grenades, and other fire works, to be rolled down a breach.

BARRERIA, in botany, a genus of the syngenesia monogamia class and order. The essential character is, calyx five toothed, very small; corolla five parted; style short; stigma trifid. There is but one species, a tree of Guiana, which rises to the height of 40 or 50 feet.

BARRICADE, a warlike defence, consisting of barrels and similar vessels filled with earth, stones, &c. or trees cut down, against an enemy's shot, or assault; but generally pales which are crossed with battoons as long as a half pike, bound about with iron at the feet.

Barricade, in the marine, a strong wooden rail supported by pillars, and extending as a fence across the foremost part of the quarter deck. In ships of war, the intervals between the pillars are filled with cork, old cable, &c. About a foot above the rail, there extends a double rope netting; and between the two parts of the netting are stuffed hammocks, seamen's bedding, &c. to intercept small shot fired by swivel guns and muskets in time of battle.

BARRIER, in fortification, a kind of fence made at a passage, retrenchment, &c. composed of great stakes, about four or five feet high, placed at the distance of eight or ten feet from one another, with transums, or overthwart rafters, to stop either horse or foot that would enter or rush in with violence.

BARRINGTONIA, in botany, a genus of the polyandria order, and monadelphia class of plants, the characters of which are: female, the calyx diphyllous above, with a drupa which it crowns; and the seed is a quadrilocular nut. There is but one species known, *viz.*

Barringtonia speciosa, a native of China and Otaheite.

BARRISTER, in common law, a person qualified and empowered to plead and defend the cause of clients in the courts of justice. They are of two sorts: the outward or outer barristers, who, by their long study in, and knowledge of, the law, which must be for a term of five years at least, are called to public practice, and always plead without the bar. The inner barristers are those who, because they are either attorney, solicitor, serjeant, or counsel to the king, are allowed out of respect, the privilege of pleading within the bar. But at the rolls, and some other inferior courts, all barristers are admitted within the bar.

BARROW, in the salt works, wicker cases almost in the shape of a sugar loaf, in which the salt is put to drain.

Barrows, a name usually given to those hillocks or mounds of earth which were anciently raised over the bodies of deceased heroes, and persons of distinguished character. These are considered by some antiquarians as the most ancient sepulchral monuments in the world.

BARRULET, in heraldry, the fourth of the bar, or the one half of the closset: an usual bearing in coat armour.

BARRULY, in heraldry, is when the field is divided bar ways, that is, across from side to side, into several parts.

BARRY, in heraldry, is when an escutcheon is divided bar ways, that is, across from side to side, into an even number of partitions, consisting of two or more tinctures, interchangeably disposed.

Barry *bendy* is when an escutcheon is divided evenly, bar and bend ways, by lines drawn transverse and diagonal, interchangeably varying the tinctures of which it consists.

Barry *pily* is when a coat is divided by several lines drawn obliquely from side to side, where they form acute angles.

BARTERING, in commerce, the exchanging of one commodity for another, or the trucking wares for wares, among merchants. Such was the original and natural mode of commerce, there being no buying till money was invented, though, in exchanging, both parties are buyers and sellers. The only difficulty in this way of dealing lies in the due proportioning the commodities to be exchanged, so as that neither party sustain any loss.

The value of the goods bartered are always equal to the product of the quantities bartered into their respective rates. Therefore multiply the given quantity and rate of one commodity, and this product divided by the rate of the other commodity, will give the quantity, or divided by the quantity will give the rate.

BARTON is used in the west of England for the demesne lands of a manor: also for the manor house; and in some parts for outhouses, &c.

BARTONIA, in botany, a genus of the class tetandria, monogynia order of plants; the essential character is, the calyx four parted, corolla, do. capsule one celled, two valved. There are but two species.

1. B. Verna. Corolla white, flowers about the beginning of January, a native of Georgia.

2. B. Paniculata, corolla white, flowers in August, a native of Pennsylvania. (*a*)

BARTRAMIA, in botany, a genus of plants of the class cryptogamia, order musci: there are five species. 1. The B. Oederiana. 2. B. Crispa. 3. B. Longiseta. 4. B. Marchica, and 5. B. Menziesii. (*a*)

BARTSIA, *painted cup*, a genus of the angiospermia order, and didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is bilbous, emargined, and coloured; the corolla less coloured than the calyx, with its upper lip longer than the under one. There are five species, of which the principal are,

1. Bartsia alpina, the mountain eye bright cow wheat. It is a native of Britain, and is found near rivulets in hilly countries. Sheep and goats eat it.

2. Bartsia viscosa, marshy, or yellow marsh eye bright, is about 10 or 12 inches high, with an erect stalk, downy and unbranched: the leaves are sessile, spear shaped, and a little viscous; the flowers are yellow, and the plant dries black. It is found in marshy places in Cornwall.

BARULES, in church history, certain Christians who held that the Son of God had only a phantom of a body; that souls were created before the world, and that they lived all at one time.

BARYTES, in mineralogy and chymistry, an earth that was discovered by Scheele in 1774, and the first account of its properties was published by him in his Dissertation on Manganese.

The experiments of Scheele were confirmed by Bergmann, who gave the earth the name of terra ponderosa. Morveau gave it the name of barote, and Kirwan of barytes; which last was approved of by Bergmann, and is now universally adopted. Different processes for obtaining barytes were published by Scheele, Bergmann, Wiegleb, and Afswelius; but little addition was made to the properties ascertained by the original discoverer, till Dr. Hope published his experiments in 1793. In 1797, our knowledge of its nature was still further extended by the experiments of Pelletier, Fourcroy, and Vauquelin.

1. Barytes may be obtained from ponderous spar, or sulphat of barytes as it is now called, by the following process, for which we are indebted to Vauquelin. Reduce the mineral to a fine powder; mix it with the eighth part of its weight of charcoal powder, and keep it for some hours red hot in a crucible, and it will be converted into sulphuret of barytes. Dissolve the sulphuret in water, and pour nitric acid into the solution, and the sulphur will be precipitated. The solution, which consists of nitric acid combined with barytes, is to be filtered and evaporated slowly till it crystalizes. Put the crystal into a crucible, and expose it to a strong heat; the nitric acid is driven off, and the barytes remains in a state of purity.

Another method attended with less expense was pointed out long ago by Dr. Hope, and has been since proposed by several foreign chymists without taking any notice of the original discoverer. The method is this: Decompose the sulphat of barytes, by heating it strongly along with charcoal powder. The product is to be treated with water to dissolve every thing that is soluble: and the liquid, being filtered, is to be mixed with a solution of carbonat of soda. A white powder falls. Wash this powder; make it up into balls with charcoal, and heat it strongly in a crucible. When these balls are treated with boiling water, a portion of barytes is dissolved, which crystalizes as the water cools.

Barytes obtained by the first method is a grayish white porous body, which may be very easily reduced to powder. It has a harsh and more caustic taste than lime; and when taken into the stomach proves a most violent poison. It has no perceptible smell. It tinges vegetable blues green, and decomposes animal bodies like the fixed alkalies, though not with such energy.

Its specific gravity, according to Fourcroy, is 4; but according to Hassenfratz, only 2.374. But there is reason to conclude, from the method employed by this philosopher, that the specific gravities which he assigns are all too low.

When heated it becomes harder, and acquires internally a bluish green shade. When exposed to the blow pipe on a piece of charcoal, it fuses, bubbles up, and runs into globules, which quickly penetrate the charcoal. This is probably in consequence of containing water, for Lavoisier found barytes not affected by the strongest heat which he could produce.

When exposed to the air, it immediately attracts moisture; in consequence of which it swells, heat is evolved, and the barytes falls to a white powder, just as happens to quicklime when water is sprinkled on it. After the barytes is thus slacked, it gradually attracts carbonic acid, and loses its acrid properties, its weight being increased. It cannot therefore be kept pure except in close vessels.

When a little water is poured upon barytes it is slacked like quick lime, but more rapidly, and with the evolution of more heat. The mass becomes white, and swells considerably. If the quantity of water is sufficient to dilute it completely, the barytes crystalizes in cooling, and assumes the appearance of a stone composed of needle form crystals; but when exposed to the air it gradually attracts carbonic acid and falls to powder.

Water is capable of dissolving 0.05 parts of its weight of barytes. This solution, which is known by the name of barytes water, is limpid and colourless, has an acrid taste, and converts vegetable blues first to a green and then destroys them. When exposed to the air, its surface is soon covered with a stony crust, consisting of the barytes combined with carbonic acid.

Boiling water dissolves more than half its weight of barytes. As the solution cools, the barytes is deposited in crystals; the shape of which varies according to the rapidity with which they have been formed. When most regular, they are flat hexagonal prisms. These crystals are transparent and colourless, and appear to be composed of about 53 parts of water and 47 of barytes. When exposed to the heat of boiling water, they undergo the watry fusion; that is to say, the water which they contain becomes sufficient to keep the barytes in solution. A stronger heat makes the water fly off. When exposed to the air, they attract carbonic acid, and crumble into dust. They are soluble in $17\frac{1}{2}$ parts of water at the temperature of 60°; but boiling water dissolves any quantity whatever: the reason of which is evident; at that temperature their own water of crystalization is sufficient to keep them in solution.

Barytes undergoes no change from light; neither is it capable, as far as is known, of combining with oxygen.

None of the simple combustibles combine with it except sulphur and phosphorus.

Sulphuret of barytes may be formed by mixing its two ingredients together, and heating them in a crucible. The mixture melts at a red heat, and when cold forms a mass of a reddish yellow colour, without any smell, which is sulphuret of barytes. This sulphuret decomposes water with great rapidity: sulphureted hydrogen is formed, which, combining with the sulphuret, converts it into a hydrogenated sulphuret. This change takes place whenever the sulphuret is moistened with water, or even exposed to the atmosphere. When boiling water is poured upon sulphuret of barytes, a great quantity of sulphureted hydrogen is formed almost instantaneously, which combines with the water and occasions the solution of the sulphuret. When the solution cools, a great number of brilliant white crystals are deposited.

Phosphuret of barytes may be formed by putting a mixture of phosphorus and barytes into a glass tube close at one end, and heating the mixture by putting the tube upon burning coals. The combination takes place very rapidly. This phosphuret is of a dark brown colour, very brilliant and very fusible. When moistened, it exhales the odour of phosphureted hydrogen gas. When thrown into water it is gradually decomposed, phosphureted hydrogen gas is emitted, which takes fire when it comes to the surface of the water, and the phosphorus is gradually converted into phosphoric acid.

Barytes is not acted on by azote; but it combines readily with muriatic acid, and forms a compound called muriat of barytes.

Barytes has no action on metals; but it is capable of combining with several of the metallic oxides, and forming with them compounds which have not hitherto been much examined. For instance, if poured into a solution of silver or lead in nitric acid, it precipitates the first brown, and the second white; but if an excess of barytes water is added, the precipitates are redissolved.

Barytes does not combine with the alkalies. Its component parts are unknown; but it resembles the alkalies in so many of its properties, that it is thought the composition of both is analogous.

BASALTES, in natural history, a kind of stone of a very fine texture, of a deep glossy black, resembling that of polished steel, and mixed with no other colour, nor any extraneous matter of any kind. The most remarkable quality of this stone is its figure, being never found in strata, but standing up in the form of regular angular columns, composed of a number of joints, one placed on and nicely fitted to another, as if formed by the hands of a skilful workman. It is remarkably hard and heavy, will not strike fire with steel, and is a fine touchstone.

The basaltes was originally found in columns in Ethiopia, in fragments in the river Tmolus, and some other places; we now have it frequently, both in columns and small pieces, in Spain, Russia, Poland, near Dresden, and in Silecia; but the noblest store in the world seems to be that called the giant's causeway in Ireland, where it rises far up in the country, runs into the sea, crosses its bottom, and rises again on the opposite land.

The constituent parts of this mineral are:

Silex -	44
Alumina -	16
Oxyd of iron	16
Lime -	9
Water -	5
Soda - -	4
Muriatic acid	1
	95.

Besides the use of basalt in building and paving, it is now employed as an ingredient in the manufacture of glass bottles; and when calcined and pulverized it makes excellent mortar, which has the property of hardening under water.

A dispute is still carried on in the philosophical world concerning the origin of basaltes; some considering it as a crystalization in water, others regarding it as a species of lava.

BASARUCO, in commerce, a small base coin in the East Indies, being made only of very bad tin.

BASE, in geometry, the lowest side of the perimeter of a figure: thus, the base of a triangle may be said of any of its sides, but more properly of the lowest, or that which is parallel to the horizon. In rectangled triangles, the base is properly that side opposite to the right angle.

BASE *of a solid figure*, the lowest side, or that on which it stands; and if the solid has two opposite parallel plane sides, and one of them is the base, then the other is called the base also.

Base *of a conic section*, a right line in the hyperbola and parabola, arising from the common intersection of the secant plane, and the base of the cone.

Base, in architecture, is used for any body which bears another, but particularly for the lower part of a column and pedestal.

The base of a column is that part between the shaft and the pedestal, if there be any pedestal, or if there be none, between the shaft and the plinth, or zocle. The base is different in the different orders. See Plates Architecture.

Base, in fortification, the exterior side of the polygon, or that imaginary line which is drawn from the flanked angle of a bastion to the angle opposite to it.

Base, in gunnery, the least sort of ordnance, the diameter of whose bore is $1\frac{1}{4}$ inch, weight 200 ponnds, length 4 feet, load 5 pound, shot $1\frac{1}{2}$ pound weight, and diameter $1\frac{1}{8}$ inch.

Base *line*, in perspective, the common section of a picture, and the geometrical plane.

Base, or Basis. By this term modern chymists express either species or families of saline matters, which differ with regard to the acid, but agree as to the alkali, earth, or metallic oxyd, which they contain. Thus, salts with the base of potash include all those which are formed by the combination of the several acids with potash. Salts with an alkaline base comprehend those, the bases of which are potash, soda, or ammonia, as distinguished from those with earthy or metallic bases.

The term base is used to denote species; as when we say sulphuric acid is composed of oxygen united with a base of sulphur: the vegetable acids consist of oxygen and componnd base of hydrogen and carbon. The term is also used more indefinitely; as phosphate of lime is the base of animal bone, azote is the base of muscular fibre; that is, the characteristic or principal part.

Base, in law. Base estate, such as base tenants have in their hands. Base tenure, the holding by villenage or other customary services, as distinguished from the higher tenures in capite, or by military service. Base fee, is to hold in fee at the will of the lord, as distinguished from soccage tenure. Base court, any court not of record.

BASELLA, *climbing nightshade*, from Malabar, a genus of the pentandria class of plants and trigynia order, and in the natural method ranking under the 12th order, holoraceæ. The calyx is wanting; the corolla is seven cleft, with the two opposite divisions broader, and at last berried; there is one seed. There are four species, but the two following suffice to give an idea of the plant:

1. Basella alba, with oval, waved, flaccid leaves, and small flowers and fruit. These plants will climb to a considerable height, and send forth a great number of branches; so they should be trained up to a trellis, or fastened to the back of the stove, otherwise they will twist themselves about whatever plants stand near them.

2. Basella rubra, with red leaves and simple footstalks, has thick, strong, succulent stalks and leaves, which are of a deep purple colour. This plant will climb to the height of 10 or 12 feet, provided it is kept in a stove. The flowers have no great beauty, but it is cultivated on account of the odd appearance of its stalks and leaves, and the flowers of a whitish green colour tipped with purple. The berries are said to be used for staining calicoes in India. Mr. Miller assures us, that he has seen a very beautiful colour drawn from them, but which did not continue long when used in painting. He is of opinion, however, that a method of fixing the colour might be invented, in which case the plant would be very useful. This, the Scotch Encyclopedists apprehend, might be accomplished by means of solution of tin in aqua regia, which has a surprising effect both in brightening and giving durability to other vegetable colours. Both species are propagated from seeds, which should be sown in a moderate hotbed in spring, and treated afterward as stove plants.

BASEMENT, the lower part or story of a building, when it is in the form of a pedestal, with a base or plinth, die, and cortice or plat band.

BASHAW, a Turkish governor of a province, city, or other district.

Bashaws include beglerbegs; and sometimes sangiacbegs; though a distinction is sometimes made, and the name bashaw is appropriated to the middle sort, or such as have two ensigns or horse tails carried before them. Those who have the honour of three tails, are called beglerbegs; and those who have only one, sangiacbegs.

BASIL, in botany. See Ocymum.

Basil, among joiners, the sloping edge of a chissel, or of the iron of a plane, to work on soft wood: they usually make the basil twelve degrees, and for hard wood eighteen: it being remarked that the more acute the basil is, the better the instrument cuts; and the more obtuse, the stronger and fitter it is for service.

Basil, *order of St.* the most ancient of all the religious orders, was very famous in the East. It passed into the West about the year 1057, and was held in great esteem, especially in Italy. By their rules, the Italian monks of that order fast every Friday in the year: they eat meat but three times a week, and then but once a day; they work all together at certain hours of the day: their habit is nearly like that of the Benedictines, and they wear a small beard like the fathers of the mission.

BASILIC, in ancient architecture, a term used for a large hall, or public place, with aisles, porticos, galleries, tribunals, &c. where princes sat and administered justice in person.

BASILICA, in anatomy, the interior branch of the axillary vein, running the whole length of the arm.

BASILICON, in pharmacy, an epithet for a great many compositions to be found in the ancient medicinal writers: but it more particularly denotes an officinal ointment, composed of wax, resin, pitch, and oil of olives, from hence called tetrapharmacum.

BASILICS, a body of the Roman laws, translated into Greek. The basilics comprehend the institutes, digests, code, novels, and some edicts, of Justinian and other emperors.

BASILICUS, in astronomy, cor leonis, a fixed star of the first magnitude in the constellation Leo.

BASILIDIANS, in church history, a branch of gnostics who maintained that Christ's body was only a phantom, and that Simon the Cyrenian suffered in his stead.

BASILISK, in military affairs, a large piece of ordnance, being a forty-eight pounder, and weighing about seven thousand two hundred pounds.

BASKETS *of earth*, in the military art, called by the French corbeilles, are small baskets used in sieges, on the parapet of a trench, being filled with earth. They are

about a foot and a half high, about a foot and a half diameter at the top, and eight or ten inches at bottom; so that being set together, there is a sort of embrasure left at their bottoms, through which the soldiers fire without exposing themselves.

Baskets are made of rushes, splinters, or willows; which last, according to their manner of growth, are called osiers and sallows. They thrive best in moist places; and the proprietors of such marsh lands, generally let what they call the willow beds to persons who cut them at certain seasons, and prepare them for basket makers. To form an osier bed, the land should be divided into plots, six, eight, or ten feet broad, by narrow ditches; and if there is a power of keeping water in these cuts at pleasure, by means of a sluice, it is highly advantageous in many seasons. Osiers planted in small spots, and along hedges, will supply a farmer with hurdle stuff, as well as with a profusion of all sorts of baskets. The common osier is cut at three years, but that with yellow bark is permitted to remain a year longer.

When the osiers are cut down, those that are intended for white work, such as baskets used in washing, are to be stripped of their bark or rinds while green. This is done by means of a sharp instrument fixed into a firm block: the osiers are placed over this, and stripped of their covering with great velocity. They are then dried, and put in bundles for sale. Before they are worked up, they must be soaked in water, which gives them flexibility. The basket maker usually sits on the ground to his business, unless when the baskets are too large for him to reach their upper parts in that position.

Hampers and other coarse work are made of osiers without any previous preparation except soaking. It requires no great capital either of money or ingenuity to exercise the business of a basket maker. Some expert workmen make a variety of articles of wicker manufacture, as work baskets of different descriptions, table matts, small baskets used for fruit at desserts, &c.

The ancient Britons were noted for their ingenuity in making baskets, which they exported in large quantities. They were of very elegant workmanship, and bore a high price. Martial takes notice of them:

> "A basket I, by painted Britons wrought,
> And now to Rome's imperial city brought."

Basket, as a measure, denotes an uncertain quantity; as, a basket of medlars is two bushels, of asafœtida from 20 to 30lb. weight.

BASON, in mechanics, a term used by glass grinders for a dish of copper, iron, &c. in which they grind convex glasses, as concave ones are formed on spheres; and by hatters for a round iron mould, in which they form the matter of their hats; and also for a leaden one for the brims of hats, having an aperture in the middle, of a diameter sufficient for the largest block to go through.

Bason, *sale by the*, at Amsterdam, is a public sale made by authority, over which presides an officer appointed by the magistrates. It is so called because, before the lots are delivered to the highest bidder, they commonly strike on a copper bason, to give notice that the lot is going to be adjudged.

BASS, in music, that part of a concert which is most heard, which consists of the gravest and deepest sounds, and which is played on the largest pipes or strings of a common instrument, as of an organ, lute, &c. or on instruments larger than ordinary for that purpose, as bass viols, bassoons, bass hautboys, &c. The bass is the principal part of a musical composition, and the foundation of harmony; for which reason it is a maxim among musicians that when the bass is good the harmony is seldom bad.

Bass, *thorough*, is the harmony made by the bass viols, or theorbos, continuing to play both while the voices sing, and the other instruments perform their parts, and also filling up the intervals when any of the other parts stop. It is played by cyphers marked over the notes on the organ, spinnet, harpsichord, &c. and frequently simply and without cyphers, on the bass viol, and bassoon.

Bass, *counter*, is a second or double bass, where there are several in the same concert.

BASSET, a game at cards, said to have been invented by a noble Venetian, for which he was banished. The persons concerned in it are a dealer, or banker; his assistant, who supervises the losing cards; and the punter, or any one who plays against the banker.

BASSIA, in botany, a genus of the dodecandria class of plants, and monogynia order, the characters of which are: the calyx is quadriphyllous; the corolla octofid, with the tube inflated; the stamina are 16; and the drupe is quinquespermos. There are three species, natives of Malabar and the South Seas.

BASSOON, a musical instrument of the wind sort, blown with a reed furnished with eleven holes, and used as a bass in a concert of hautboys, flutes, &c.

BASSORIA, a genus of the pentandria monogynia class and order. The essential character is: calyx five cleft, spreading with a short tube; berry ovate, knobbed, and many seeds. There is but one species, an herbaceous plant of Guiana, of little note.

BASSO RELIEVO, or Bass relief, a piece of sculpture, where the figures or images do not project or stand out far above the plane on which they are formed. Whatever figures or representations are thus cut, stamped, or otherwise wrought, so that not the entire body, but only part of it is raised above the plane, are said to be done in relief, or relievo; and when the work is low, flat, and but a little raised, it is called low relief; when a piece of sculpture, a coin, or a medal, has its figure raised so as to be well distinguished, it is called bold, and we say its relief is strong.

The origin of basso relievo is thought to have been described in the story of the maid of Corinth, related by Pliny; who says that Dibutades, the Sicyonian potter, her father, invented a method of taking likenesses in the following manner: His daughter being in love with a young man who was going on foreign service, she circumscribed the shadow of his face with lines upon the wall by lamp light; her father took the impression in clay, and baked it among his vases.

BASS VIOL, a musical instrument of the same form with that of a violin, but much larger. It is struck with a bow as that is, has the same number of strings, and has eight stops, which are subdivided into semi-stops: its sound is grave, and has a much nobler effect in a concert than that of the violin.

BASTARD, one who is born of any woman not married, so that his father is not known by order of the law. A bastard by our English laws, is one that is not only be-

gotten, but born out of lawful matrimony. As all children born before matrimony are bastards, so are all children born so long after the death of the husband, that by the usual course of gestation they could not be begotten by him.

If a man marry a woman grossly big with child by another, and even within three days afterward she is delivered, the issue is no bastard. 1 Danv. Abr. 729.

If a child is born within a day after marriage between parties of full age, if there be no apparent impossibility that the husband should be the father of it, the child is no bastard, but supposed to be the child of the husband. 1 Rol. Abr.

If a bastard die without issue, though the land cannot descend to any heir on the part of the father, yet to the heir on the part of the mother, being no bastard, it may; because he is of the blood of the mother, but he has no father. 2 Rol. Abr. If a bastard die intestate, leaving neither widow nor issue, the king is entitled to the personality. 2 Blacks. 505.

The incapacity of a bastard consists principally in this, that he cannot be heir to any one, neither can he have heirs but of his own body: for being nullius filius, he is therefore of kin to no one, nor has he any ancestor from whom any inheritable blood can be derived. 3 Salk. 66.

A bastard may be made legitimate, and capable of inheriting, by the transcendent power of an act of parliament. 1 Blacks. 459.

If any single woman be delivered of a bastard child which shall be chargeable or likely to become chargeable; or shall declare herself to be with child, and that such child is likely to be born a bastard, and to be chargeable; and shall in either of such cases, in an examination to be taken in writing, on oath, before one justice of the peace of the county, &c. where such parish or place shall lie, charge any person with having gotten her with child, it shall be lawful for such justice, upon application made to him by the overseers of the poor of such parish, or one of them, or by any substantial householder of any extra parochial place, to issue out his warrant for the immediate apprehending such person so charged as aforesaid, and for bringing him before such justice, or before any other justices of the peace of such county, city, or town corporate: and the justice, before whom such person shall be brought, shall commit him to the common gaol or house of correction, unless he shall give security to indemnify such parish or place; or shall enter into a recognisance, with sufficient security, upon condition to appear at the next general quarter session, or general session of the peace. 6 Geo. II. c. 31.

Though a bastard child is prima facie settled where born, yet this rule admits of several exceptions: as where a bastard is born under an order of removal, and before the mother can be sent to her place of settlement: or if a woman be delivered on the road in transitu, while the officers are conducting her, by virtue of an order of removal; or if the child be born in the house of correction, or in the house of industry, of any hundred or district, or in a lying-in hospital, it shall follow the mother's settlement. 1 Sess. Cr. 33. 94. 2 Salk. 474. 13 Geo. III. c. 29. 20 Geo. III. c. 36.

Bastard *eigne*, is a son born before marriage, whose parents afterward intermarry, and by the civil law he is mulier, or lawful issue, but not by the common law. 2 Inst. 99.

BASTARDY, arms of, in heraldry, should be crossed with a bar, fillet, or traverse from left to right. Bastards were formerly not allowed to carry the arms of their father, and therefore they invented arms for themselves, and this is still done by the natural sons of a king.

BASTION, in the modern fortification, a huge mass of earth, faced usually with sods, sometimes with brick, and rarely with stone, standing out from a rampart, whereof it is a principal part, and is what, in the ancient fortification, is called a bulwark, *propugnaculum*.

A bastion consists of two faces and two flanks; the faces include the angle of the bastion, and their union makes the outmost or the salient angle, called also the angle of the bastion; and the union of the two faces to the two flanks makes the side angles, called also the shoulders or epaules; and the union of the two other ends of the flanks to the two curtains makes the angles of the flanks.

In regard to the bastion, the great rule is, that every part of it be seen and defended from some other part: whence mere angles are not sufficient, but flanks and faces are necessary. For the proportion of the faces, they are not to be less than 24 Rhineland perches, nor more than 30. The flanks of a bastion, in case they stand at the same angle under the line of defence, are so much the better the longer they are; whence they must stand at right angles to the line of defence: and the disposition of the flanks makes the principal part of fortification, as it is that on which the defence chiefly depends, and which has introduced the various forms of fortifying. The angle of the bastion must be more than 60 degrees, otherwise it will be too small to give room for guns, and will either render the line of defence too long, or the flanks too short; so that it must be either a right angle or some intermediate one between that and 60 degrees; for it is disputed whether or not it should exceed a right angle. See Fortification.

BASTON, or Batoon, in heraldry, a kind of bend, having only one third of the usual breadth.

BAT, see Vespertilio.

Bat, Bate, or Batz, a small copper coin, mixed with a little silver, current in several cities in Germany; it is worth four crutzers. It is also a coin of Switzerland, current at five livres or one hundred sols French money.

BATCHELOR, in the livery companies of London, are those not yet admitted to the livery.

Batchelors, in the university, are persons who have taken the first degree in the liberal arts and sciences. Before a person can be admitted to this degree at Oxford, it is necessary that he study there four years; three years more may entitle him to the degree of master of arts; and in seven years more he may commence batchelor of divinity. At Cambridge the degrees are usually taken as at Oxford, excepting in law and physic, in either of which the batchelor's degree may be taken in six years. In France the degree of batchelor of divinity is attained in five years' study, that is, in two years of philosophy and three of divinity.

BAT fowling, a method of catching birds in the night, by lighting some straw or torches near the place where they are at roost; for upon beating them up they fly to

the flame, where being amazed, they are easily caught in nets, or beaten down with bushes fixed to the end of poles, &c.

BATH, warm, cold, vapour, &c. See MEDICINE and MINERAL WATERS.

BATH, in Hebrew antiquity, a measure of capacity, containing the tenth part of an omer, or seven gallons and four pints, as a measure for things liquid: or three pecks and three pints, as a measure for things dry.

BATH. See BALNEUM, and CHYMISTRY.

BATH, *knights of*, a military order in England, supposed to have been instituted by Richard the Second, who limited their number to four: his successor, however, Henry IV. increased them to forty-six. Their motto was *tres in uno*, signifying the three theological virtues.

This order derived this denomination from a custom of bathing before they received the golden spur. It is seldom or never conferred but at the coronation of kings, or the inauguration of a prince of Wales or duke of York. They wear a red riband beltwise.

The order of the bath, after remaining many years extinct, was revived under George the First, by a solemn creation of a great number of knights.

BATIS, in botany, a genus of the tetandria order and dioecia class of plants, the characters of which are: of the male the amentum is four ways imbricated, and both the calyx and corolla are wanting: of the female the amentum is ovate, the involucrum diphyllous; calyx and corolla wanting; the stigma is bilobate and sessile; the berries condunate and four seeded. There is but one species, *viz.* batis mantina, a native of Jamaica.

BATMAN, in commerce, a kind of weight used at Smyrna, containing six okes of four hundred drams each, which amount to sixteen pounds, six ounces, and fifteen drams, of English weight.

BATTALION, or BATALLION, an undetermined body of infantry in regard to number, generally from 600 to 1000 men. The companies of grenadiers and light infantrymen having been detached from their several corps and formed into separate battalions, the guards at present consist of nine battalions. The different companies are likewise considerably augmented; so that it is impossible to affix any specific standard to their complement of men. The royal regiment of artillery consists of four battalions. Sometimes regiments consist each of one battalion; but if more numerous, are divided into several battalions, according to their strength; so that every one may come within the numbers mentioned. A battalion in one of our marching regiments consists of 1000 and sometimes of 1200 men, officers and noncommissioned included. When there are companies of several regiments in a garrison to form a battalion, those of the eldest regiment post themselves on the right, those of the second on the left, and so on until the youngest fall into the centre. The officers take their posts before their companies, from the right and left, according to seniority. Each battalion is divided into four divisions, and each division into two subdivisions, which are again divided into sections. The companies of grenadiers being unequal in all battalions, their post must be regulated by the commanding officer.

BATTEN, a name that workmen give to a scantling of wooden stuff, from two to four inches broad, and about one inch thick, the length undetermined.

BATTER, a cannonade of heavy ordnance, from the first or second parallel of entrenchment, against any fortress or works.

BATTER in breach, implies a heavy cannonade of many pieces directed to one part of the revetement from the third parallel.

BATTERING, in military affairs, implies the firing with heavy artillery on some fortification or strong post possessed by an enemy, in order to demolish the works.

BATTERING *pieces* are large pieces of cannon used in battering a fortified town or post.

It is judged by all nations that no less than 24 or 18 pounders are proper for that use. Formerly much larger calibres were used; but, as they were so long and heavy, and very troublesome to transport and manage, they were for a long time rejected, till adopted among the French, who, during the late war, have brought 36 and 42 pounders into the field.

BATTERING *train*, a train of artillery used solely for besieging strong places, inclusive of howitzers: all heavy 24, 18, and 12 pounders, come under this denomination; as likewise the 13, 10, and 8 inch mortars and howitzers.

BATTERY, in military affairs, implies any place where cannon or mortars are mounted, either to attack the forces of the enemy, or to batter a fortification: hence batteries have various names, agreeable to the purposes they are designed for.

BATTERY, *gun*, is a defence made of earth faced with green sods or fascines, and sometimes made of gabions filled with earth: it consists of a breastwork, parapet, or epaulement, of 18 or 20 feet thick at top, and of 22 or 24 at the foundation; of a ditch 12 feet broad at the bottom, and 18 at the top, and 7 feet deep. They must be $7\frac{1}{2}$ feet high. The embrasures are 2 feet wide within, and 9 without, sloping a little downward, to depress the metal on occasion. The distance from the centre of one embrasure to that of the other is 18 feet; that is, the guns are placed at 18 feet distance from each other; consequently the merlins, or that part of solid earth between the embrasures, are 16 feet within and 7 without. The genouilliers, or parts of the parapet which cover the carriage of the gun, are generally made $2\frac{1}{2}$ feet high from the platform to the opening of the embrasures; though this height ought to be regulated according to the semi-diameter of the wheels of the carriage or the nature of the gun. The platforms are a kind of wooden floors, made to prevent the cannon from sinking into the ground, and to render the working of the guns more easy; and are, strictly speaking, a part of the battery. They are composed of five sleepers or joists of wood, laid lengthwise, the whole length of the intended platform; and to keep them firm in their places, stakes must be driven into the ground on each side; these sleepers are then covered with sound thick planks, laid parallel to the parapet; and at the lower end of the platform, next to the parapet, a piece of timber six inches square, called a hurter, is placed, to prevent the wheels from damaging the parapet. Platforms are generally made 18 feet long, 15 feet broad behind, and 9 before, with a slope of about 9 or 10 inches, to prevent the guns from recoiling too much, and for bringing them more easily forward when loaded. The dimensions of the platforms, sleepers, planks, hurters, and nails, ought to be regulated according to the nature of the pieces that are to be mounted.

The powder magazines to serve the batteries ought to be at a convenient distance from them, as also from each other; the large one at least 55 feet in the rear of the battery, and the small ones about 25. Sometimes the large magazines are made either to the right or left of the battery, in order to deceive the enemy; they are generally built five feet under ground; the sides and roof must be well secured with boards, and covered with earth, clay, or something of a similar substance, to prevent the powder from being fired; they are guarded by sentinels. The balls are piled in readiness beside the merlins, between the embrasures.

The officers of the artillery ought always to construct their own batteries and platforms, and not the engineers, as is practised in England; for certainly none can be so good judges of those things as the artillery officers, whose daily practice it is; consequently they are the most proper to direct the situation and to superintend the making of batteries on all occasions.

Battery, *mortar*. These kinds of batteries differ from gun batteries, only in having no embrasures. They consist in a parapet of 18 or 20 feet thick, $7\frac{1}{2}$ high in front, and 6 in the rear; of a berme $2\frac{1}{2}$ or 3 feet broad, according to the quality of the earth; of a ditch 24 feet broad at the top, and 20 at the bottom. The beds must be 9 feet long, 6 broad, 8 from each other, and 5 feet from the part; they are not to be sloping like the gun platforms, but exactly horizontal. The insides of these batteries are sometimes sunk two or three feet into the ground, by which they are much sooner made than those of cannon. The powder magazines and piles of shells are placed as is mentioned in Gun battery.

Battery, *ricochet*, so called by its inventor, M. Vauban, and first used at the siege of Aeth, in 1697. It is a method of firing with a very small quantity of powder, and a little elevation, so as just to fire over the parapet; and then the shot will roll along the opposite rampart, dismounting the cannon, and driving or destroying the troops. In a siege they are generally placed at about 300 feet before the first parallel, perpendicular to the faces produced, which they are to enfilade. Ricochet practice is not confined to cannon alone; small mortars and howitzers may effectually be used for the same purpose. They are of singular use in action to enfilade the enemy's ranks; for when the men perceive the shells rolling about with their fuses burning, expecting them to burst every moment, the bravest among them will not have courage to wait their approach and face the havock of their explosion.

Batteries, *horizontal*, are such as have only a parapet and ditch; the platform being only the surface of the horizon made level.

Batteries, *breach* or *sunk*, are such as are sunk upon the glacis with a design to make an accessible breach in the faces or salient angles of the bastion and ravelin.

Batteries, *cross*, are such as play athwart each other against the same object, forming an angle at the point of contact; whence greater destruction follows, because what one shot shakes, the other beats down.

Batteries, *oblique*, or *batteries en echarpe*, are those which play on any work obliquely, making an obtuse angle with the line of range, after striking the object.

Batteries, *enfilading*, are those that sweep or scour the whole length of a straight line, or the face or flank of any work.

Batteries, *redan*, are such as flank each other at the salient and rentrant angles of a fortification.

Batteries, *direct*, are those situated opposite to the place intended to be battered, so that the balls strike the works nearly at right angles.

Batteries, *reverse*, are those which play on the rear of the troops appointed to defend the place.

Batteries, *glancing*, are such whose shot strike the object at an angle of about 20°, after which the ball glances from the object, and recoils to some adjacent parts.

Batteries, *joint*, } when several guns fire on the
Batteries, *camarade*, } same object at the same time. When ten guns are fired at once, their effect will be much greater than when fired separately.

Batteries, *sunk*, are those whose platforms are sunk beneath the level of the field, the ground serving for the parapet, and in it the embrasures are made. This often happens in mortar, but seldom in gun, batteries. Battery sometimes signifies the guns themselves placed in a battery.

Batteries, *fascine*, } are batteries made of those ma-
Batteries, *gabion*, } chines where sods are scarce and the earth very loose or sandy.

Battery *planks*, are those planks or boards used in making platforms.

Battery *boxes*, are square chests or boxes filled with earth or dung, used in making batteries, where gabions and earth are not to be had; they must not be too large, but of a size that is governable.

Battery *nails*, are wooden pins made of the toughest wood, with which the planks that cover the platforms are fastened. Iron nails might strike fire against the iron work of the wheels, in recoiling, &c. and be dangerous.

Battery, in law, the striking, beating, or offering any violence to another person, for which damages may be recovered. But if the plaintiff made the first assault the defendant shall be quit, and the plaintiff amerced to the king for his false suit. Battery is frequently confounded with assault, though, in law, they are different offences; for in the trespass for assault and battery, one may be found guilty of assault, yet acquitted of the battery; there may therefore be assault without battery, but battery always implies an assault. See Assault.

BATTLE, in the military art, has ever been the last resource of good generals. A situation where chance and accident often baffle and overcome the most prudential and most able arrangements, and where superiority of numbers by no means ensures success, is such as is never entered into without a clear necessity for so doing. The fighting a battle only because the enemy is near, or from having no other formed plan of offence, is a direful way of making war. Darius lost his crown and life by it; king Harold of England did the same; and Francis I. at Pavia lost the battle and his liberty. King John of France fought the battle of Poictiers, though ruin attended his enemy if he had not fought.

The true situation for giving battle is when an army's situation cannot be worse, if defeated, than if it does not fight at all: and when the advantage may be great, and the

loss little. Such was the duke of Cumberland's at Hastenbeck, in 1757, and prince Ferdinand's at Vellinghausen, in 1761. The reasons and situations for giving battle are so numerous, that to treat of them all would fill a large volume; we shall therefore content ourselves with the following: There may be exigencies of state that require its army to attack the enemy at all events. Such were the causes of the battle of Blenheim in 1704, of Zorndorff in 1758, of Cunnersdorff in 1759, and of Rosbach in 1757. To raise a siege, to defend or cover a country. An army is also obliged to engage when shut up in a post. An army may give battle to effect its junction with another army, &c.

The preparations for battle admit of infinite variety. By a knowledge of the detail of battles, the precept will accompany the example. The main general preparations are, to profit by any advantage of ground; that the tactical form of the army be in some measure adapted to it; and that such form be, if possible, a form tactically better than the enemy's; and, in forming the army, to have a most careful attention to multiply resources, so that the fate of the army may not hang on one or two efforts; to give any particular part of the army, whose quality is superior to such part of the enemy's army, a position that ensures action; and, finally, to have a rear by nature or if possible by art, capable of checking the enemy in case of defeat.

The dispositions of battles admit likewise of an infinite variety of cases; for even the difference of ground which happens at almost every step, gives occasion to change the disposition or plan; and a general's experience will teach him to profit by this, and take the advantage the ground offers him. It is an instant, a *coup-d'œil*, which decides this; for it is to be feared the enemy may deprive you of those advantages, or turn them to his own profit; and for that reason this admits of no precise rule, the whole depending on the time and the occasion.

With regard to battles, there are three things to be considered: what precedes, what accompanies, and what follows the action. As to what precedes the action, you should unite all your force, examine the advantage of the ground, the wind, and the sun, things not to be neglected, and choose if possible a field of battle proportioned to the number of your troops.

You must post the different kinds of troops advantageously for each: they must be so disposed as to be able to return often to the charge; for he who can charge often with fresh troops, is commonly victorious. Your wings must be covered so as not to be surrounded; and you must observe that your troops can assist each other without any confusion, the intervals being proportioned to the battalions and squadrons.

Great care must be taken about the regulation of the artillery, which should be so disposed as to be able to act in every place to the greatest advantage; for nothing is more certain than that, if the artillery is well commanded, properly distributed, and manfully served, it will greatly contribute to gaining the battle, being looked upon as the general instrument of the army, and the most essential part of military force. The artillery must be well supplied with ammunition, and each soldier have a sufficient number of cartridges. The baggage, provisions, and treasure of the army, should, on the day of battle, be sent to a place of safety.

In battle, where the attacks are, there is also the principal defence. If an army attacks, it forms at pleasure; it makes its points at will: if it defends, it will be sometimes difficult to penetrate into the designs of the enemy, but when once found, succour succeeds to the discovery. Ground and numbers must ever lead in the arrangement of battles; impression and resource will ever bid fairest for winning them.

Battle *array*, } the method and order of arranging
Battle, *line of*, } the troops in order or line of battle; the form of drawing up the army for an engagement. This method generally consists of three lines, *viz.* the front line, the rear line, and the reserve.

The second line should be about 300 paces behind the first, and the reserve at about 5 or 600 paces behind the second. The artillery is likewise divided along the front of the first line. The front line should be stronger than the rear line, that its shock may be more violent; and that, by having a greater front, it may more easily close on the enemy's flanks. If the first line has the advantage, it should continue to act, and attack the enemy's second line, terrified by the defeat of their first. The artillery must always accompany the line of battle in the order it was at first distributed, if the ground permit it; and the rest of the army should follow the motions of the first line, when it continues to march on after its first success.

Battle *ax*, an offensive weapon, formerly much used by the Danes, and other northern infantry. It was a kind of halbert, and did great execution when wielded by a strong arm.

Battle, *naval*, the same with a sea fight or engagement between two fleets of men of war. Before a naval battle, every squadron usually subdivides itself into three equal divisions, with a reserve of certain ships out of every squadron to bring up their rear. Every one of these, observing a due birth and distance, are in the battle to second one another; and the better to avoid confusion and falling foul of each other, to charge, discharge, and fall off by threes or fives, more or less, as the fleet is greater or smaller. The ships of reserve are instructed either to succour and relieve those that are any way in danger, or to supply and put themselves in the place of those that shall be made unserviceable.

As for a fleet consisting but of few ships, when obliged to fight in an open sea, it should be brought up to battle in only one front, with the chief admiral in the middle of them, and on each side of him the strongest and best provided ships of the fleet.

The English mode of fighting at sea has latterly been, to bear down on the enemy in a single column or line, to break the line of the enemy ship by ship, raking them by a broadside as they pass. By thus breaking the enemy's line at a particular part, an opportunity is afforded, wind and other circumstances favouring, of cutting off any given number of their force, and reducing them to an equality. Such was the famous manœuvre of sir John Jervis off cape St. Vincent, by which he gained a victory over a very superior force. In the ever memorable battle of Trafalgar, lord Nelson bore down upon the combined fleets in two columns, which brought them to action sooner and to

greater advantage than could otherwise have been effected. The disposition of the enemy on the same occasion was most masterly; for by ranging a part of their fleet behind the others in the intervals between ship and ship, they rendered it so much the more difficult and hazardous to break their line.

BATTLEMENTS, in architecture, are indentures or notches in the top of a wall or other building, in the form of embrasures, for the sake of looking or firing through them.

BATZ, a copper coin mixed with some silver, and current at different rates, according to the alloy, in Nuremberg, Basil, Fribourg, Lucerne, and other cities of Germany and Switzerland.

BAUHINIA, mountain ebony, a genus of the monogynia order and decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is quinquefid and deciduous; the petals are oblong, expanded, and clawed, the superior one more distant, all inserted on the calyx; the capsule is a legumen. There are 13 species, all trees and shrubs, which are propagated by seeds; and must be sown in hotbeds, and afterward kept in a bark stove. The most remarkable are,

1. Bauhinia aculeata, with a prickly stalk, very common in Jamaica and other American sugar islands, where it rises to 16 or 18 feet, with a crooked stem, and divides into many irregular branches armed with strong short spines, compound winged leaves, each having two or three pair of lobes ending with an odd one, which are oblique, blunt, and indented at the top. The stalks are terminated by several long spikes of yellow flowers, succeeded by bordered pods about three inches long, containing two or three swelling seeds. It is called in America the savin tree, from its strong odour somewhat resembling the common savin.

2. Bauhinia acuminata, with oval leaves, is a native of both the Indies, and rises with several pretty strong, upright, smooth stems, sending out many slender branches. The flowers come out at the extremities of the branches, three or four in a loose bunch; some of the petals are red or striped with white, but others are plain upon the same branch; the stamina and style are white, and stand out beyond the petals. The wood of this tree is very hard, and veined with black; whence its name of mountain ebony.

3. Bauhinia divaricata, with oval leaves, whose lobes spread different ways. This grows naturally in great plenty on the north side of the island of Jamaica. It seldom rises more than five or six feet, but divides into several branches. The flowers grow in loose panicles at the end of the branches, have a white colour, and a very agreeable scent. They appear the greatest part of summer, which makes it one of the greatest beauties of the hothouse.

4. Bauhinia tomentosa, with heart shaped leaves, is a native of Campeachy, and rises to 12 or 14 feet, with a smooth stem dividing into many branches, having two smooth pointed lobes. Every branch is terminated by a long spike of yellow flowers, so that when these trees are in flower they make a fine appearance.

5. Bauhinia variegata, with heart shaped leaves, and lobes joining together, is a native of both the Indies. It rises with a strong stem upward of 20 feet, dividing into many strong branches. The flowers are large, and grow in loose panicles at the extremity of the branches. They are of a purplish red colour marked with white, and have a yellow bottom. The flowers have a very agreeable scent, and are succeeded by compressed pods about six inches long, and three quarters of an inch broad, containing three or four compressed seeds in each.

BAWN, or Ban, to construct and secure with branches of trees an area enclosed with thick ditches of earth, square or circular, impaled with wooden stakes or branches of trees, and surrounded with a deep trench. Numerous remains of such fortresses are found in Britain, Germany, and other countries in the north of Europe.

BAY, among farmers, a term used to signify the magnitude of a barn; as, if a barn consists of a floor and two heads, where they lay corn, they call it a barn of two bays. These bays are from 14 to 20 feet long.

BAYONET, in the military art, a short broad dagger, fitted for the bore of a firelock, to be fixed there after the soldier has fired.

BAYS, in commerce, a sort of open woollen stuff, having a long nap, sometimes friezed, and sometimes not. This stuff is without wale, and is wrought in a loom with two treddles, like flannel. It is chiefly manufactured at Colchester, and Bocking in Essex, where there is a hall called the Dutch bay hall, or raw hall. The exportation of bays was formerly much more considerable than at present. However, the English bays are still sent in great quantities to Spain and Portugal, and even to Italy.
